The first question was to determine whether the membership composition manipulation of the contingency and relationship factors actually had measurable effects on probation supervision. The answer was an unqualified yes (Table 7). Program managers, including the screening interviewers and both the preservice and inservice trainers of volunteers, gave their most positive evaluations to those volunteers who were the more interpersonally skilled. The probationers assigned to the more interpersonally skilled officers—volunteer or professional—reported more open and warm relationships with their officers than did the probationers assigned to the less interpersonally skilled officers. Probationers' reports on the amount of real help and assistance offered by their officers varied positively with officer SOC scores. Finally, during audiotaped supervision sessions, it was the more conventionally socialized officers who were making more anticriminal statements—and who were most likely to approve of their probationer's anticriminal expressions and disapprove of their probationer's procriminal expressions. The more conventionally socialized officers were also less likely to offer noncontingent friendly expressions.

The in-program recidivism of the probationers was analyzed in a 2 (Officer EMP) × 2 (Officer SOC) × 2 (Officer ICO) format, with the professional status of officers and the probationers' age and sex as covariates. The main effects of the officer factors were not statistically reliable but there was an EMP × SOC interaction ($p<.004$). In a different setting, with different operational definitions of the contingency and relationship factors, and

Table 7. The Effects of Officer Empathy and Socialization on the Socioemotional Climate and Anticriminal Contingencies During Probation Supervision: Pearson *r*'s (Study V)

	Empathy	Socialization

Friendly Expressions	(*ns*)	−.40**

* $p<.05$.
** $p<.01$.

Table 8. Proportion of Probationers "Recidivating" by Probation Officer Empathy and Socialization Levels (Study V)

	Socialization		
Empathy	Low	High	$p<$
Low	.163 (37)	.418 (31)	.02
High	.298 (48)	.148 (72)	.05
$p<$	.10	.01	

Note: The recidivism rates were adjusted for probationer age, sex and professional status of officer. The unadjusted rates yield the same pattern of results. The number of probationers on which the proportions were based are recorded in parentheses.

with a different measure of anticriminal influence, the interaction plotted in Table 8 was a direct confirmation of the Andrews et al. (forthcoming) findings, previously outlined in Table 6. With anticriminal contingencies in effect (high SOC officers), the relationship factor (officer EMP) was negatively related to recidivism: the probationers assigned to the more empathetic officers "recidivated" at lower rates than did probationers with the less empathetic officers. With the less anticriminal contingencies in effect (low SOC officers), officer EMP scores were positively related to probationer recidivism. The particularly poor performance of the probationers with the low-EMP/high-SOC officers (the austere moralistic officers in Grief and Hogan's [1973] terms) represents the first convincing empirical confirmation of Cressey's (1955) and Empey and Rabow's (1961) fear of establishing "rejection of the rejectors."

A close inspection of Table 8 might suggest that both the low-EMP/low-SOC and high-EMP/high-SOC combinations represented relatively neutral conditions, while the other two conditions were associated with the active production of criminal behavior. Note that there was not a significant difference in outcome between the low-EMP/low-SOC and high-EMP/high-SOC conditions. We expected, however, that the recidivism rates for the high-EMP/high-SOC officers were inflated by the fact that EMP and ICO are positively correlated: the more empathetic officers identified most with offenders ($r = .23, p<.05$). Thus, and in view of the a priori significance of ICO, officers in the high-EMP/high-SOC categories were further split on the basis of ICO. Relative to the probationers assigned to the other types of officers, the probationers of the high-EMP/high-SOC/low-ICO officers "recidivated" at significantly lower rates (Table 9). However, splitting the low-EMP/low-SOC officers on ICO had no such effect on the recidivism of their probationers.

To maintain continuity with the Community Group studies and to compare behavior (recidivism) with verbalization, probationer attitude change was also monitored as a function of officers' interpersonal skills and conventional orientation. Consistent with the Community Group studies and DA, it was those probationers assigned to the high-EMP/high-SOC officers who not only "recidivated" least, but also showed both the greatest increases in respect for the law, courts, and police, and the greatest reductions in tolerance for law violation and identification with offenders. The attitudinal effects were evident regardless of probationers' age, sex, prescores, "faking good" or the professional status of their officers (Table 9).

Table 9. Mean Change in the Criminal Sentiments of Probationers and Recidivism by Officer Empathy and Socialization Levels (Study V)

	High Empathy, High Socialization Officers	Other Officers	*F*	*p*
Law, Courts, Police	4.41	1.23	4.98	.03
Tolerance for Law Violations	−2.35	−0.35	5.81	.02
Ident. with Criminal Others	−1.19	−0.09	3.51	.06
Recidivism (%)	5.37	25.2	5.19	.02

Note: The tabled mean attitude change scores have been adjusted for prescores, probationers' age and sex, changes on the "faking good" scale, and professional status of officers. See text regarding the recidivism effects.

In sum, the studies have provided strong and consistent evidence that the contingency and relationship principles of DA have causal significance with reference to both criminal attitudes and criminal behavior. The self-management factor remains to be reviewed.

The Self-Management Principle

A recurring problem for reviewers of DA has been that of defining "excess." The suggestion here is that one way we can avoid the problem of operational counts of the number of criminal and anticriminal definitions is by focusing, instead, on *changes* on measures relevant to definitions. The focus then becomes that of examining the behavioral correlates of induced *shifts* in the balance of definitions. This can readily be done, assuming we have measures of definitions at two separate points in time, the theoretical and technical wherewithall to induce the changes, and an independent measure of criminal behavior at time two and/or at a later follow-up period.

Toward this end, Andrews et al. (1979) examined the correlations between probationer attitude change and recidivism with statistical controls introduced for probationers' prescores, the professional status of the probationer's officer, and probationer age and sex. In a battery of 24 attitude and personality scales, only six measures of change were reliably predictive of reduced recidivism: more positive attitudes toward the law, courts, and police (−.20, $p<.01$); decreased tolerance for law violations (.15, $p<.05$); decreased identification with offenders (.15, $p<.05$); increased socialization (−.17, $p<.05$); decreased psychopathy (.18, $p<.01$); and decreased wish to exert control over others (.14, $p<.05$). While there may be discussion about the relevance of the latter two change-measures to DA, the first four rather clearly represent shifts in the direction of definitions unfavorable to violation of the law. The multiple correlation between attitude change and recidivism was .48 ($p<.05$), a figure of impressive magnitude, given the well-known problems associated with self-report measures and the fact that we did not have an independent measure of self-management skills.

The above-noted finding is generally consistent with DA—but not sufficiently convincing when one adopts a behavioral perspective on self-management, since the functional process has not been identified. Recall the assumption that changes at the level of attitudes and beliefs would be most evident at the behavioral level when the individual possesses and practices self-management skills. In a study which might well chart an exciting new course for symbolic interactionism, Wormith (1977) attempted to isolate experimentally the conditions under which attitude and belief change become evident in deviant versus conventional behavior. In a 2 × 2 factorial design, he independently manipulated the quality of an attitude-change program to which prisoners were exposed, as well as the programmed opportunity for enhancement of self-management skills. The attitude-change manipulation involved random assignment of prisoners to one of two types of Community Groups: one, in which the volunteers were trained to explicitly model and reinforce anticriminal expressions; and the other, a routine Community Group. The self-management program involved systematic training of prisoners in behavioral principles, including self-observation, self-instruction, and self-consequation. The comparison level of the self-management training factor was participation in a Community Recreation Group. Wormith monitored the behavioral effects of the four program conditions on two reliable institutional-conduct indices involving prosocial versus antisocial changes in participants' behavior toward staff and peers. The analyses revealed a clear Attitude Training × Self-Management Training interaction on prisoner behavior outside of the training context. Those residents who received self-management training, plus high-level attitude training, showed behavioral changes in the prosocial direction; while those who received self-management training, in combination with the lower-level attitude change program, exhibited behavioral changes in the antisocial direction. The Wormith study, like the other

Community Group studies, awaits followups regarding impact on postprogram recidivism.

Summary and Conclusions

The studies and findings have suggested and supported a number of general conclusions regarding how social and behavioral scientists may approach matters concerning the causal and applied significance of their theories:

(a) The Community Group and Ottawa Probation projects, in conjunction with the findings of other controlled evaluations of correctional programs reviewed elsewhere (Andrews, 1979a; 1979b), provide impressive evidence in total that the principles of DA have causal significance and that the principles are of immediate importance to those involved in the design and management of correctional programs. Without due and joint consideration of the contingency and relationship factors, correctional programming may inadvertently produce not simply *zero* impact—but perhaps *negative* impact—on correctional clients. Similarly, although the data-base is still very light on the point, it may be worse than unproductive to focus on criminal learning without equal attention being paid to the processes by which learning is translated into performance.

(b) The analytic and technological power as well as the conceptual flexibility that a behavioral orientation can bring to the study of deviance is too great to be glibly dismissed, as has been done by sociologists strongly committed to symbolic interactionism. Similarly, a commitment to the development of a "clinical sociology," a commitment still strongly associated with the group dynamics tradition, cannot continue to blind programmers and evaluators to the paucity of their returns, relative to complementary behavioral approaches.

(c) Systematic, controlled, and theoretically integrated research programs should precede the design and implementation of large-scale and intrusive interventions in the lives of individuals. If a few small, but careful, investigations of the assumptions underlying guided-group interaction programs had been completed prior to their wide-scale implementation, then many young persons would have been spared the massive intrusion which such programs represent, relative to routine probation. In rejecting the clinical tradition, the clinical sociologists also overlooked a key ethical principle: the explicit testing of the assumptions underlying intervention as opposed to ideological commitment to those assumptions.

(d) Glaser's (1962; 1974) increasingly impassioned pleas for a bridging of the gap between theory and practice will be more systematically adhered to as practitioners recognize the guidance which theory can provide, and as theorists recognize the potential of rigorous program evaluation as a means of testing the causal significance of theoretical principles. The studies reviewed spoke to both concerns.

(e) Program-evaluation research provides an opportunity for sociologists to examine the effects on individual behavior of controlled variations on basic structural factors such as the membership, role, and status composition of social systems. Some of the studies in the review provided concrete examples of the Durkheimian "social fact"—albeit, examples derived from social systems so miniature that Durkheim might have yawned.

(f) Program-evaluation research provides a unique opportunity for interdisciplinary (yet theoretically integrated) research on how structure maintains the contingencies within social systems, and on how those contingencies, in turn, influence the attitudes and behavior of the individuals within the system. This was a major implication of the Burgess and Akers (1966) reformulation of DA; and the studies reviewed in the present paper provide evidence relevant to both levels of analysis. Hopefully, it will be not just sociologists and psychologists who participate in such research. The emerging but still distinctly atheoretical policy and management sciences might do well to consider that it is primarily through role changes (for example, by the training of workers on practice-relevant dimensions), status changes (for example, by policy statements on rights and obligations), and changes in membership composition (for example, by selecting workers on practice-relevant dimensions) that significant organizational change may bring about more cost-efficient attainment of publicly stated goals. An ongoing study of probation services is examining the effects of simultaneously controlled variation of each of these three major elements of social structure (Andrews and Kiessling, 1978).

SOCIAL CLASS AND PSYCHOLOGICAL DISTRESS*

RONALD C. KESSLER
University of Michigan

PAUL D. CLEARY
Rutgers University

American Sociological Review 1980, Vol. 45 (June:463–478)

Although a negative relationship between socioeconomic position and psychological distress has consistently been documented in community surveys, we know very little about the determinants of this relationship. The dominant interpretation argues that distress is caused by exposure to stressful life experiences, that lower status people are highly exposed to this sort of experience, and that statistical adjustment for differential exposure can account for the higher rates of distress among lower status people. In this paper, a different interpretation is emphasized. It is shown that differential exposure to stress, while clearly of some importance, accounts for only a minor part of the status/distress relationship, and that a far more central role is played by class differences in responsiveness to stress—that is, by the fact that lower status people are more likely than middle and upper status people to develop symptoms of distress when exposed to problematic life experience. Several plausible interpretations of this differential responsiveness are presented and an analysis strategy developed to evaluate their relative contributions. Results of an empirical evaluation document the importance of social origins and mobility experiences as determinants of differential responsiveness to stress.

In this paper, we consider the relationship between socioeconomic status and mild forms of psychological distress[1] as measured by symptom-screening scales in community surveys of mental illness. The comparatively higher rates of distress in the lowest social strata in these surveys is one of the most consistently documented findings in the literature on psychiatric epidemiology (Dohrenwend, 1970; 1973; Dohrenwend and Dohrenwend, 1969; Fried, 1975; Langner and Michael, 1963; Myers et al., 1974). Yet, despite the fact that a great deal of empirical and theoretical work has focused on this relationship, we know very little about the factors accounting for the higher rates of distress among lower class people (Liem and Liem, 1978; Wheaton, 1978).

Over the last decade, research on this problem has focused almost exclusively on the hypothesis that greater exposure to stressful life experiences accounts for the higher rates of distress in the lower classes (Dohrenwend, 1970; Myers et al., 1972; 1974). This hypothesis is based on evidence that emotional distress can result from exposure to stressful experiences of either a traumatic nature (Dohrenwend, 1975; Myers et al., 1972) or a more stable and enduring nature (Pearlin and Johnson, 1977; Pearlin and Lieberman, 1978), and

Halaby, David Mechanic, Gillian Stevens, Blair Wheaton, and two anonymous reviewers for helpful comments on earlier drafts.

[1] The terms "distress" and "emotional disorder" are used throughout this paper because they are terms used in the literature and are familiar and meaningful to most readers. We would agree with Clausen (1979:97) however, who asserts that "... what we call 'mental disorder' consists of a variety of behaviors, disordered thought processes, and abnormal emotional states: some reflect the psychological influence of organic disease or genetic constitution; some are reactions to intense psychological stress; some are inadequate or maladaptive personal strategies; and some are deviant modes of behaving, thinking, and feeling that are common to members of particular subcultures." While a full discussion of these issues is beyond the scope of this paper, we would like to make it quite clear that many of the phenomena which are commonly referred to as mental illness are not necessarily, in our opinion, "illness" and that the measure of psychological disorder which will be described later in this paper does not necessarily reflect psychiatric "illness." Similarly, although some terms, such as "vulnerability," imply inadequate coping or defense, it is not necessarily the case that the experience of distress in response to environmental events is a dysfunctional response.

on the plausible assumption that lower class people are more highly exposed to experiences of both sort.

Beginning with the pioneering work of Langner and Michael (1963), efforts to support empirically this hypothesis have failed. It is true that most research on stressful life experiences finds lower class people exposed to more of the life problems that have been shown to precipitate emotional distress (Dohrenwend and Dohrenwend, 1970; Myers et al., 1974). However, statistical adjustments for these differences only partly account for the higher rates of emotional distress among lower class people. Lower class respondents are more likely than people of higher class positions to exhibit symptoms of distress at any given level of exposure to stressful experiences (Langner and Michael, 1963; Kessler, 1979; Brown et al., 1975). Furthermore, the higher the level of stress, the greater the class differences in distress. The implication of these findings is that class differences in emotional distress are partly due to class differences in the influence of stress on psychological functioning. Lower class people are, for some reason(s), more responsive to stress than people of higher class positions.

For a decade after being identified in the work of Langner and Michael (1963), the observed class difference in responsiveness to stress was virtually ignored in the psychiatric epidemiological literature. Only recently have several investigators made attempts to replicate this finding in independent data sets. All of these efforts support the position that lower class people are particularly responsive to stress (Brown et al., 1975; 1977; Dohrenwend, 1973; Kessler, 1979). Indeed, a recent investigation has suggested that this differential responsiveness to stress is the key component accounting for the relationship between social class and emotional disorder (Brown and Harris, 1978).

In the following discussion, we review several plausible interpretations of this class difference in responsiveness to stress, describe an analysis strategy for partially disentangling the influences suggested by these interpretations, and illustrate the usefulness of this strategy in an empirical application.

The Determinants of Responsiveness to Stress

It is generally agreed that the impact of stress on emotional functioning is mediated by characteristics of both the individual and his environment (Dohrenwend and Dohrenwend, 1970). The individual defines the significance of a potentially distressing situation, and this appraisal determines whether or not the situation will be experienced as threatening (Lazarus et al., 1974). Personality characteristics then act to multiply or reduce the impact of subjectively appraised stress. Anxiety proneness (Andrews et al., 1978) and low threshold for uncertainty (Smith et al., 1978), for instance, have both been shown to increase emotional arousal associated with demanding situations. High self-esteem (Kaplan, 1970) and perceived personal control (Johnson and Sarason, 1979), on the other hand, have both been shown to reduce perceptions of threat (Chan, 1977). In addition, concrete coping responses can vary in their effectiveness in routinizing stressful experiences (Pearlin and Schooler, 1978). All of these comprise what has come to be called "social competence," the individual's overall level of psychosocial functioning as seen in his ability to deal with the ongoing stresses associated with living (Smith, 1968).

The individual's environment is implicated in this coping process, both indirectly and directly. Experiences in living indirectly influence coping by helping shape the appraisals, beliefs, values, and behavior dispositions that make up one's coping repertoire. That is, the environment helps shape the individual's *intrapsychic resources* for coping. The environment can also influence responsiveness to stress more directly, by providing *social resources* for acting on the problem situation that creates stress. We are thinking here not only of financial and political power but also of guidance concerning coping options and of emotional support, both of which can be extremely important in helping a person deal effectively with a problem (Cobb, 1976; Miller and Ingham, 1976; Henderson, 1977; Henderson et al., 1978).

With these considerations as a background, it is relatively easy to offer a plausible explanation for the fact that stressful life experiences have their most damaging psychological effects among lower class people. This is so because lower class people are disadvantaged in their access to both intrapsychic resources and social resources. On the intrapsychic side, we know that feelings of self-worth and control over the environment are both positively related to class (Pearlin and Schooler, 1978; Rosenberg and Pearlin, 1978), as are several other intrapsychic characteristics thought to play some part in coping (Dohrenwend and Dohrenwend, 1970; Kohn, 1976; 1977). On the social side, we know that the poor are disadvantaged not only in terms of objective resources, like money and political power (Antonovsky, 1979), but also in their comparatively limited access to supportive social relationships and stable community ties (Dohrenwend and Dohrenwend, 1970; Liem and Liem, 1978).

Yet, while we know something about the broad outlines of the coping process and something about the coping resources differentially available to persons of varying class position, it is less clear how these various resources come to play a part in the comparatively greater emotional responsiveness of the poor. What are the relative roles of intrapsychic and social resources? And, if it seems that intrapsychic resources play a central part, how can we account for the fact that these resources are comparatively less available to the poor? These are centrally important questions, the answers to which (or, at least, more information about which) are needed for a more complete understanding of class differences in responsiveness to stress than we presently possess.

Contending Perspectives on Class Differences in Responsiveness to Stress

For researchers concerned with the relationship between social class and psychological disorder, the major research issue over the last several decades has been to disentangle the relative importance of two contending perspectives on this relationship: what have come to be known as the social-selection and social-causation perspectives (Dohrenwend, 1975; Liem and Liem, 1978; Wheaton, 1978). The former argues that people with psychological disabilities are more common in the lower socioeconomic strata because of natural competitive conditions that distribute people across the class structure according to their abilities. The social-causation argument, by comparison, holds that the life conditions to which lower class people are subjected lead to comparatively high levels of emotional disorder. In short, then, the contending hypotheses are: (1) that one's mental state helps determine his social position; and (2) that one's social position helps determine his mental state.

It is of some importance to recognize that the social-selection argument, as stated in this general form, is completely agnostic as to the relative importance of nature and nurture in bringing about psychological disorder. There has been a tendency, in the literature, to associate the social-selection argument with a genetic theory of causation (Dohrenwend and Dohrenwend, 1969; Dohrenwend, 1975). While it is true that if genetic factors play a significant role in mental disorders known to be associated with social class, then the only plausible way of understanding this fact is by positing a selection process. However, it is also perfectly conceivable that selection takes place on the basis of learned intrapsychic frailties distributed randomly (with respect to social class origins) among children who subsequently drift into the lower class as adults.

The central premise of the selection argument is that some chronic disorder *or* predisposition to disorder causes downward mobility. The traditional version of the argument has been associated with research on schizophrenia, where the symptoms of the disorder themselves are thought to be primarily responsible for downward drift (Dunham, 1965; Turner et al., 1970). Since it is inconceivable that a similar causal process (that is, symptoms themselves serving as a causal force and persisting chronically through time) could lead to downward mobility when less debilitating forms of disorder are involved, it is now believed that selection processes are of little importance in explaining the negative relationship between social class and scores on symptom screening scales in community surveys (Wheaton, 1978). However, it is perfectly conceivable that the factors which influence an individual's ability to compete successfully for social position also play a part in the ability to cope with stress. If this is so, and if we remember that class differences in mild forms of distress appear to be due largely to differences in *responsiveness* to stress, then the selection of competent copers out of the lower class and the selection of incompetent copers into the lower class could play important parts in accounting for class differences in the less debilitating psychological disorders.

We should note here that the social-selection argument tacitly assumes that intrapsychic resources are primarily responsible for class differences in responsiveness to stress. The social-causation perspective, by comparison—at least as it applies to class differences in responsiveness to stress—argues that social class largely determines the life experiences to which one is exposed, thus in large part shaping one's coping repertoire and determining access to social resources.

While the potential importance of social resources in coping with stress is obvious, several social-causation theorists have argued that class operates on responsiveness primarily by shaping intrapsychic resources. The culture of poverty theorists (Lewis, 1966), for instance, argue that individuals born into poverty go through a socialization experience tied to traditional lower class values, thus instilling in them outlooks and orientation to life that are associated with inadequate defenses and coping styles. According to this thinking, social class makes its mark on the individual primarily through childhood socialization, although the intrapsychic resources instilled in the individual during these critical formative years have a continuing influence throughout life (Langner and Michael, 1963; Liem and Liem, 1978). Other social-causation theorists, however, have argued that objective conditions of lower class existence, rather than lower class traditions, primarily determine the content of socialization experiences (Kohn, 1976; 1977). If this is true, an argument can be made that socialization is a lifelong process, one that is shaped as much by adult experiences as by those in one's childhood. This position has, in fact, been advanced (Levinson et al., 1978).

A Critical Contrast

To our knowledge, these various contending perspectives on class differences in responsiveness to stress have not been compared empirically. The approach we have taken, and which is described in this section, goes only part way in this task, leaving unresolved some important issues. Nonetheless, it succeeds in reducing, considerably, the range of plausible interpretations.

Our strategy consists of contrasting the relative influences of comparable stresses on members of different social classes on the basis of intergenerational mobility histories. Consider the patterns of intergenerational mobility diagrammed in Table 1, in which we have arbitrarily made distinctions among upper (u), middle (m), and lower (l) levels of socioeconomic status. Although all the perspectives predict that members of the lower stratum will be most vulnerable to distressing life experiences, they predict different patterns of relative influence within the more refined mobility subdivisions.

The childhood socialization perspective suggests that lower class *origins* will be associated with low resistance to stress and that the impact of a particular stress on some measure of emotional functioning will be large in cells 7, 8, and 9 in Table 1 relative to other cells—that is,

Table 1. A Hypothetical Mobility Table

	Respondent's Social Position		
	Upper	Middle	Lower
Parents' Social Position			
Upper	1	2	3
Middle	4	5	6
Lower	7	8	9

among persons born into the lower stratum, irrespective of their destinations. Consequently, if we find empirically that an observed class difference in responsiveness to some stress cannot, at least in part, be traced to differences in responsiveness among those with different class *origins,* controlling for mobility and destinations, a childhood socialization interpretation can be discounted.

The social resources perspective emphasizes differences in access to resources that can be effective in dealing with stress, thus suggesting that one's current class position (cells 3, 6, and 9) will be associated with low resistance to stress. Consequently, if we find that an observed class difference in responsiveness is not, at least in part, traceable to differences in class *destinations,* controlling for origins and mobility experiences, a social resources interpretation is discredited.

The social-selection perspective emphasizes drift into the lower classes, thus suggesting that *downward intergenerational mobility* (cells 2, 3, and 6) will be associated with responsiveness to stress. Consequently, if it can be documented empirically that social origins are not associated with responsiveness to a particular stress, we can discount the possibility that selection effects are responsible for the greater emotional impact of this stress on the poor.

The strength of this decomposition approach lies in its ability to reject particular interpretations. We learn much less here about the forces that are at work than about those that are not. For instance, if class differences in responsiveness can be traced to current social position and can be shown to be unrelated to both social origins and mobility experiences, we then can, with some confidence, reject the hypotheses that early childhood socialization or social-selection account for class differences in responsiveness. Yet we learn nothing from these data about the relative importance of adult socialization experiences and current social resources in helping the socially advantaged cope with stress.[2]

This illustration presages a pattern of relationships to be reported here, at which point we will have more to say about it. The important point to make at *this* stage of this discussion, though, is that while our approach is only partially successful in disentangling the various perspectives on responsiveness reviewed earlier, it can be effective in reducing considerably the range of plausible interpretations. Furthermore, although the strength of the approach lies in its ability to reject certain otherwise plausible interpretations, it can be augmented (in certain instances) with other data so that we can arrive at some relatively clear understanding of the causal processes at work in a particular instance.

Data and Procedures

Data: The data used to evaluate our strategy come from the New Haven longitudinal survey of mental disorder (Myers et al., 1972; 1974). The sample consists of 720 respondents who were interviewed both in 1967 and 1969, from an original random sample of 938 adults residing in New Haven, Connecticut.[3] These interviews dealt heavily with experiences that might have led to mild anxiety or depression.

---

[2] The major difficulty in making inferences about processes that might be at work lies with the socialization perspective. As we noted above, a case can be made for the premise that any life experience may function as a socialization experience. Consequently, the socialization perspective is consistent with virtually any pattern of origin/destination/mobility effects. And, so, the influence of social origins might be due to heredity—but it might instead be due to socialization; the influence of downward mobility might represent a social-selection process—but it might instead be due to socialization into a pattern of learned helplessness (Seligman, 1975).

We do believe that, at times, it is possible to infer that one process rather than another is at work. Yet we are on much less certain ground here than we are in rejecting an interpretation that is inconsistent with the decomposition results. For instance, if class differences in responsiveness to stress can be traced to differences associated with social origins and not to mobility or to destinations, we can, with some confidence, reject the hypothesis that class differences in access to social resources importantly influence responsiveness. But we cannot be clear, on the basis of these patterns alone, about the relative importance of socialization tied to social origins and genetic factors that might be heavily concentrated in the lower class. However, an additional consideration argues in favor of the socialization hypothesis. If we are to believe that genetic predispositions to disorder are concentrated in the lower class, then we must also believe that selection factors are at work. If this is so, we would expect some sort of downward mobility effect in the data. That such an effect does not exist argues against the genetic hypothesis.

The criterion measure of distress used here is Macmillan's (1957) symptom checklist scale as modified by Gurin et al. (1960). This scale is very similar in content to other "screening scales" of mild distress used in community surveys and can be interpreted as a measure of subjectively experienced mood disorder. In all, the scale is made up of 20 statements about bodily feelings that indicate moods of depression and anxiety through psychophysiological symptoms. These symptoms were selected from among those most frequently presented by patients in treatment.

It should be emphasized that this scale is not intended to measure clinically defined depression or anxiety when administered in a normal population such as this one. Clinical definitions require making qualitative distinctions between "cases" and "normals" on the basis of information about constellations of symptoms. No such distinction is made here. Rather, scores on the scale are used in this paper to order respondents on a continuum of reported magnitude of subjectively experienced distress. Scores on the scale range from 20 (all of the symptoms are reported as occurring "often") to 80 (symptoms are reported as occurring "never").

Socioeconomic status is measured by Hollingshead's Index of Social Position, a five-point scale which is a weighted function of occupation and education created specifically to describe the class structure of New Haven (Hollingshead and Redlich, 1958).[4] As a means of highlighting the contrasts between the lower and upper class strata, we have combined the upper three categories of this index (I–III) in our analysis. This combined category includes not only people who are normally considered members of the upper class but also those normally considered members of the middle class. Category IV on the scale consists largely of skilled and semiskilled workers and their spouses, while category V consists of unskilled workers, their spouses, and persons who are principally supported by some form of public assistance.

In preliminary analyses, we examined several stress measures and found two with significantly higher influences on the Gurin scores of lower class than higher class respondents.[5] The first of these is an index of reported undesirable life events experienced over the two years between data collections. The index consists of 17 events[6] weighted by the life change ratings reported in Holmes and Masuda (1974) and then summed to give an overall score for each individual. The second is an index of physical health problems, made up from a symptom checklist. Since the Gurin scale of emotional stress consists largely of psychophysiological symptoms, great care was taken in constructing this health problems index. The interview schedule contained a list of some 44 physical health complaints. Some of these were clearly psychosomatic. To create the health problems index we selected a subset of 16 complaints for which a psychosomatic component is probably of only minor importance. Larger weights were given to those that were most serious. Each respondent's score is a sum of these weighted complaints.[7]

---

[3] According to Myers et al. (1972:93), "8 percent refused to be reinterviewed; 11 percent had moved out of the area; and 4 percent had died."

[4] A reviewer of an earlier draft pointed out that the decision to combine education and occupation into a single index partially masks intragenerational downward mobility between educational attainment and later job attainment. This decision was made because we wished to focus here on intergenerational mobility. Nonetheless, the reviewer's point is well taken and a more detailed analysis than that presented here could proceed in two parallel steps—first studying intergenerational mobility and then intragenerational mobility.

[5] Five stress measures were examined in all. One (an index of desirable life events) had no meaningful influence on Gurin scores in any of the three social status subsamples examined. Two others (an index of ambiguous life events and an index of financial problems) had significant, but comparable, influences on Gurin scores in all three subsamples.

[6] The 17 events, and their weights in the index, are as follows: (1) moved to a worse neighborhood, 114; (2) widowed, 880; (3) divorced, 630; (4) separated, 541; (5) trouble with in-laws, 195; (6) serious injury or accident, 426; (7) death of a loved one, 380; (8) demoted or changed to a less responsible job, 228; (9) laid off temporarily, 305; (10) business failed, 205; (11) trouble with boss, 174; (12) out of work for over a month, 305; (13) fired, 384; (14) financial status a lot worse than usual, 288; (15) foreclosure, 248; (16) detention in jail, 474; and (17) loss of driver's license, 34.

Procedures: The origin, destination, and mobility patterns of interest in Table 1 can be described completely by eight dummy variables. However, in the New Haven data, two of the downward mobility cells (from I–III to IV, n = 14 and from I–III to V, n = 4) are small, requiring the use of only six dummy variables to describe mobility completely. A variety of ways exists to assess the importance of these contrasts. Our approach was to begin with origin, destination, and mobility effect patterns and to refine our contrasts in light of preliminary findings.

Consider Table 2, which provides a schematic view of the mobility table and our parameterization. The additive model of upper (u), middle (m), and lower (l) status origin and destination effects on average symptoms ($\overline{G}_{ij}$) in the ij^th cell is:

$$\overline{G}_{ij} = b_1 + b_2D(P_m) + b_3D(P_l) + b_4D(R_m) + b_5D(R_l), \qquad (1)$$

where P represents the social status of one's parents, and R the social status of the respondent; where b_1 is the mean in cell P_1R_1 (upper status origins and upper status destinations); where $D(P_i)$ is 1 in the i^th row, 0 elsewhere; and $D(R_j)$ is 1 in the i^th column, 0 otherwise. The parameters of this model estimate the expected cell means—due to the effects of origins, destinations, and the additive component of mobility. (The latter is confounded here with the origin and destination effects. See Halaby and Sobel, 1979.)

With the two additional degrees of freedom in the table, parameters can be estimated to distinguish (a) movers from stayers and (b) upward from downward mobility. Parameters for the influence of degree of mobility (one-step or two-step in these data) cannot be estimated, since they are embedded in the mobility effects and main effects of origin and destination (Halaby and Sobel, 1979). The fully specified model is:

Table 2. Schematic Diagram of Dummy Contrast Coding

	Respondent's Social Position			
	Upper (I–III)	Middle (IV)	Lower (V)	
Parents' Social Position				
Upper (I–III)	PuRu	×	×	(Pu)
Middle (IV)	P<R		P>R	(Pm)
Lower (V)	P<R	P<R		(P1)
	(Ru)	(Rm)	(R1)	

$$\overline{G}_{ij} = b_1 + b_2D(P_m) + b_3D(P_l) + b_4D(R_m) + b_5D(R_l) + b_6D(P \neq R) + b_7D(P < R). \qquad (2)$$

When we create interaction terms representing the products of these dummy variables with a measure of stress and enter these terms along with the main effects in (2), the within-cell slopes of symptoms on stress are recoverable. Just as cell means are partitioned in (2) into the main effects of origin, destination, and nonadditive mobility, the slopes of Gurin scores on stress in each cell are partitioned into origin, destination, and nonadditive mobility components in this more complete model. By examining these components, we can make inferences about the various perspectives on responsiveness to stress.

Results: Table 3 presents the results of three regression analyses, one each for the upper (Index of Social Position I–III), middle (IV), and lower (V) status subgroups. In each subgroup, Time 2 (1969) Gurin scores are regressed on Time 1 (1967) Gurin scores and two indicators of stressful life experience.[8] The first indi-

---

[7] These 16 complaints are: (1) eye trouble, (2) ear trouble, (3) sinus trouble, (4) throat trouble, (5) bronchitis, (6) pneumonia, (7) tuberculosis, (8) boils and abscesses, (9) diabetes, (10) kidney trouble, (11) bodily injury, (12–14) operations, with coding for up to three operations for each respondent, (15) cancer or tumors, and (16) tooth trouble, not including routine prophylaxis. Double weights were assigned to complaints 6, 7, 12, 13, and 14 and a triple weight to complaint 15.

[8] Note that each prediction equation includes the Time 1 (1967) Gurin score as a predictor of the Time 2 Gurin score. This inclusion addresses the possibility, raised by several critics of life events research (Brown, 1974; Rabkin and Struening, 1976; Dohrenwend et al., 1978), that emotionally distressed people often select themselves into stressful situations. For

† Source: New Haven panel data (Myers et al., 1975), restricted to respondent with valid data on both his/her current Social Position and parents' Social Position. All regressions include controls for age, sex, and marital status. Slopes for WTUE are inflated by a factor of 100.

cator is the index of undesirable life events (WTUE). The second indicator is the index of physical health problems (HP). Excluded from the analysis are 124 respondents who failed to report either their own social positions or those of their parents.

There is a clear pattern of increased influence of stress as we move from higher to lower social positions. Neither physical health problems nor undesirable events significantly influence reports of emotional distress among people in positions I–III. Health problems exert a much greater influence in the status IV subsample, one that is both statistically significant in that subsample ($t = 4.523$, $p \leq .05$) and also significantly higher than the comparable coefficient in the I–III subsample ($t = 2.145$, $p \leq .05$). Finally, in the lower status subsample both physical health problems and undesirable events have significant effects on emotional functioning ($t = 3.809$, $t = 3.171$, respectively, both $p \leq .05$), although the WTUE coefficient does not differ significantly from the comparable coefficient in the middle status subsample ($t = 1.249$).[9]

---

instance, a visible emotional depression might lead to being fired from one's job. Anxiety might cause symptoms of physical illness. In the face of these possibilities, one cannot assume that observed relationships between stress and distress are due solely to the causal impact of stress on distress. Fortunately, the fact that we are working with panel data makes it possible for us to adjust for the confounding of causal direction by controlling Time 1 distress. In this way, we can include events that might be partially confounded by selection effects in our indexes and partial out these effects by means of statistical controls.

Over the course of the two years, symptoms of mild distress are relatively stable in the subsamples, with coefficients of stability between .43 and .58. This suggests that a good part of the variance in distress in this sample is due to disorders of considerable duration. Note, though, that both the standardized stability coefficients and the metric autoregression coefficients increase in magnitude as we move from lowest to highest class subsamples. These patterns argue against the suggestion that higher rates of disorder among the poor are partially due to a greater degree of stable emotional problems in this sector of society (Dohrenwend and Dohrenwend, 1965). If anything, it would seem that the stability of distress is greater among members of the higher social statuses.

[9] One reviewer of an earlier version of this paper suggested that the differential slopes observed in Table 3 might reflect a nonlinearity in the relationships between the stress indicators and Gurin scores. This could come about if, as is true for our measures of WTUE, mean levels of the stress increase substantially as we move from the higher to lower social positions. To evaluate this possibility, we estimated the following polynomial regression equation for the sample as a whole:

$$
\begin{array}{rl}
G_2 = & .496\ G_1 \\
 & (.523) \\
 & -1.500\ \text{WTUE} \\
 & (-.183) \\
 & +1.021\ \text{WTUE}^2 \\
 & (.063)
\end{array}
$$

The metric coefficients are presented in the equation, with standardized coefficients in parentheses beneath them. The linear effects of G_1 and WTUE are both significant. The quadratic coefficient is insignificant, which means that no single bend-point in the regression line captures a significantly greater degree of association between undesirable events and Gurin scores than that modelled in the linear relationship.

It is conceivable that this polynomial test overlooks subtle nonlinearities in the data. Therefore, we also estimated a series of 15 spline regressions, each

These slope differences are extremely important when considered in relation to the total difference in Gurin scores reported by respondents in the three strata. We can completely account for the significant difference in average Gurin 2 scores between the I–III and IV subsamples (means of 74.10 and 73.04, respectively) by standardizing on the slope difference associated with health problems.[10] The comparable difference in Gurin scores in the I–III and V subsamples (means of 74.10 and 71.58, respectively) is halved when we standardize on the slope differences associated with health problems and life events. These results clearly show that the differential influences are important components of the overall relationship between social position and distress.[11] However, it is worth noting that differences in average Gurin 2 scores between positions IV and V (means of 73.04 and 71.58, respectively) are reduced by only 18% when we standardize on slope differences associated with HP and WTUE. This means that slope differences are much more important in explaining the comparatively higher symptom levels of persons in social positions IV–V compared to those in positions I–III than in accounting for differences between the two comparatively lower status IV and V positions.

We now turn to an evaluation of the roles played by social-causation and social-selection factors in determining these slope differences. We will demonstrate here that mobility-related factors largely account for the comparatively greater influence of undesirable events on lower status respondents in this sample. Origin-related factors appear to be primarily responsible for the comparatively greater influence of physical health problems.

The differential influence of undesirable life events: Several models were estimated to evaluate the interactive influence of social origins, destinations, and mobility with our scale of undesirable life events on Gurin scores of distress. We began with a baseline model of predictors: Gurin 1 (1967), WTUE, and the six dummy origin/destination/mobility variables ($R^2 = .292$). Interaction terms to test the influences of origins, destinations, and mobility histories were sequentially added to this model. Only the mobility interaction model meaningfully improved on the baseline ($R^2 = .303$, $F_{2,585} = 3.385$, $p \leqslant .05$).[12]

The parameter estimates for the mobility interaction model are presented in Table 4. Here we see that upward mobility modifies the influence of life events on distress. Upwardly mobile people are *less* highly influenced by events than the nonmobile ($t = 2.529$, $p \leqslant .05$), differing in their responsiveness to each unit of WTUE by .598 on the Gurin scale. This difference remains significant when we

---

using a successively higher point on the scale as the bend-point of the spline. The results of this more detailed analysis are available on request. There was no evidence in these results of a significant nonlinearity.

[10] In other words, if people in the IV subsample were no more responsive to the effects of HP on their emotional functioning than people in the I–III subsample, their adjusted Gurin 2 scores would not differ significantly from those observed among people in the I–III subsample.

[11] This is not to say that these particular slope differences are the only components of importance in accounting for class differences in distress. There are doubtlessly a great many forces at work here, some of which work to the advantage (and some to the disadvantage) of people in the different social status positions. We are merely focusing on two of these and noting that, all else equal, these importantly contribute to the greater distress, observed empirically, among the poor.

[12] Having found that social origin and destination interactions are not significant in statistical terms, we know that the significant mobility interaction cannot completely be determined by structural mobility—that part of mobility which is related to the distribution of origin and destination statuses. However, it is possible that some part of the mobility interaction could be attributed to structural mobility and it would be informative to determine exactly how much (McClendon, 1977).

We failed in our efforts to separate the effects of structural and circulation mobility in this particular data set, each component proving too unstable to allow the estimation of a meaningful interaction parameter. We suspect, though, that it would be possible to perform a decomposition of this sort in a data set containing a more refined measure of social position and a larger sample size. This is a task we plan to pursue in our future work. In the present analysis, results are presented without controls for the origin/destination interactions, thus presenting an overall assessment of both structural and circulation mobility effects.

† Slopes for WTUE are inflated by a factor of 100.

introduce controls for sex, marital status, age, and income (.564, t = 2.379, p ≤ .05). There is no meaningful difference in influences of life events on the stable and downwardly mobile (t = .089).

These findings are inconsistent with the childhood socialization perspective and with the social resources perspective, since neither origin nor destination status is meaningfully related to responsiveness to stress. Instead, we find that upwardly mobile people are comparatively unresponsive to stress. These upwardly mobile people are, by definition, not members of the lowest class and, empirically, are less common in the IV subsample than in the I–III subsample, thus creating the aggregate picture of comparatively higher responsiveness as we move down the status hierarchy.

This pattern is consistent with a variant of the social-selection argument—that competent people born into the lower class move up the class hierarchy as they reach adulthood. It is also consistent, though, with an adult socialization interpretation—that the experience of success associated with upward mobility creates the sort of assertive coping skills needed to avoid the psychological damage that can result from undesirable life events. There is no completely convincing way to disentangle these two interpretations in the data. However, we favor the adult socialization argument on the grounds of additional considerations. If selection processes are really at work, we would predict that the remaining members of social position V—both those who were born in this social class and those who have been unable to advance socially as adults—would be highly influenced by stress, as compared to the rest of the sample. A process of this sort would appear as an exacerbating effect of position V origins, after controlling for the ameliorating effect of upward mobility. There is no evidence of such an effect, however, in our data, making us suspicious of a selection interpretation of the mobility pattern.

The plausibility of an adult socialization interpretation is suggested by the literature on human development, which emphasizes the importance of adversity for the creation of competence, especially when this adversity is encountered early in one's life (Coles, 1967; Elder, 1974). According to this reasoning, success in overcoming adversity—one important instance of which is rising above one's disadvantaged social origins—can help create in an individual the sort of personal characteristics—feelings of self-esteem, confidence, perseverance—that are the stuff of competent problem management. Successful mastery of new challenges can help the individual grow in self-esteem and confidence, both of which have been shown to be important coping resources in adulthood (Pearlin and Schooler, 1978). By the same token, failures in meeting the challenges of developmental problems can lead to feelings of powerlessness, to self-abasement, and to the use of strategies for dealing with the world that are ineffective in achieving beneficial responses to life problems (Moriarty and Toussieng, 1976; Murphy and Moriarty, 1976).

How much of these complex series of successes, failures, and alterations in self-feelings are due to inborn characteristics, how much to early socialization experiences, and how much to pure luck, are matters difficult to disentangle. However, it is quite clear from additional analyses of the basic relationship that the interactive influence of upward mobility in dampening the impact of life events is associated with social competence. We find support for this interpretation, first, in Table 5, where we examine the relationship between exposure to stressful events and the

use of tranquilizer drugs. We know that competent people are characterized by active problem-solving styles and less competent people are more likely to rely on the sort of coping devices that help them live with stress and make its effects less severe (Moos and Tsu, 1976). These latter are the styles characteristic of people who use alcohol to help them forget their problems (Pearlin and Radabaugh, 1976), and who withdraw from normal social interaction defensively (Elder, 1974). They are also the styles that characterize people who use tranquilizing medications to help them deal with their life problems (Radelet, 1977). If our interpretation of the upward mobility specification is correct, we would expect that upwardly mobile people would be comparatively unlikely to make use of these drugs when confronted with stressful life events.

The results in Table 5 support this speculation. Among the upwardly mobile, there is no meaningful relationship between exposure to undesirable life events and the use of tranquilizing drugs. There is a significant relationship between the two among other members of the sample ($t = 2.481$, $p < .05$) and among other members of the sample in the same social positions as the upwardly mobile ($t = 1.827$, $p = .080$).

Other evidence consistent with this same argument is presented in Table 6. Our analysis here is motivated by Elder's (1974) work on childhood deprivation, where a stronger relationship between deprivation and adult competence was reported for men than women. We reasoned that a similar sort of process might be at work in the relationship between upward mobility and competence. Since women can enhance their social positions by marriage rather than by success in the world of work, we would expect some upwardly mobile women to have developed fewer of the skills associated with mastery than upwardly mobile men. On the other hand, we would expect women who made their ways to the top through their own successes in the business world to be equally as competent (and perhaps more so) as men who had the same successes.

In order to test these speculations, we estimated a model of the sort presented in Table 4 separately in subgroups of the sample defined by sex and by work status. We predicted that the relative resilience of upwardly mobile people to life events would be most clearly present among men and among workers. The results in Table 6 are consistent with these expectations. There is no meaningful interactive influence of mobility and WTUE on distress among women nor among people who are not the breadwinners in their families. This interaction is strong, though, among males and among those who are breadwinners.

Taken together, these various results suggest that the comparatively lower reaction to stressful life experiences of upper status people in this sample is due to the presence among them of extremely competent copers who have been upwardly mobile from lower class origins.[13]

---

[13] It is worth noting that several other perspectives predict a relationship between social mobility and emotional distress. One of these, associated with Durkheim's discussion of anomie, has been used in recent work to account for the greater degree of mental illness in socially disintegrated communities (Leighton, 1974) and among the upwardly mobile goal-strivers (Kleiner and Parker, 1963). This per-

There is no evidence that the objective conditions of existence are of assistance in helping these people deal with the emotional problems caused by stressful life events or that cultural conditions associated with their social origins are of importance in modifying their responses to stressful events.

The differential influence of physical health problems: Several models were estimated to evaluate the interactive influence of origins/destinations/mobility and physical health problems on Gurin scores of distress. We began with a baseline model of predictors: Gurin 1, HP, and the six dummy origin/destination/mobility variables (R^2 = .301). Terms for the interactions of origins, destinations, and mobility histories with HP were added sequentially to this model. The results of these analyses are very different from those found in our analysis of life events: (1) There is no meaningful modification of the relationship between physical health problems and distress associated with mobility. (2) There is some evidence that origins and (perhaps) destinations modify the influence of health problems on distress. The best overall model is one including the interactive effects of both origins and destinations (R^2 = 3.12), a model that significantly improves on the baseline model ($F_{4,583}$ = 3.183, $p \leqslant .05$).

R^2		.312

* $P \leqslant .05$.

The parameter estimates of the origins/destinations interaction model are presented in Table 7. Here we see that the influence of physical health problems on distress is highest for those with strata IV–V origins (t = 2.104, $p \leqslant .05$). This association is not changed by controls for sex, marital status, age, and income, the metric coefficient becoming −1.679 (t = 2.292, $p \leqslant .05$) rather than −1.665 as in Table 7. There is a similar, although statistically insignificant, modification associated with destinations in strata IV or V (t = 1.428). Our suspicion is that this destination effect would be significant in a larger data set or in one in which there was a greater degree of mobility than in this sample. As it is, we cannot reject the hypothesis that origins and destinations are equally important in a pooled model of "status" effects (the sum of origins and destinations). (Data available on request.)

Leaving aside the possible importance of destinations, the data are consistent with the childhood socialization perspective, which views social origins as important in shaping patterns of interpretation and coping that can magnify or reduce the influence of stress on emotional functioning. Before pursuing this pattern in more detail, it is worth mentioning that significant social origin effects have seldom been reported in the literature on mobility and mental disorder (Eaton and Lasry, 1978). Past research, however, focused on the main effects of origins rather than on interactive effects. Even in our own analysis, we find no significant main effects of social origins on Gurin scores. We believe this failure to detect a main effect of origins, even when an interaction of

---

spective would seem to have little direct importance as an explanation of the greater amount of neurotic distress in the lower class, though.

Other perspectives on the effects of mobility all emphasize direct effects, conceptualizing mobility experiences as stresses. Some view stresses associated with mobility as most extreme on the upwardly mobile (Eaton and Lasry, 1978), while others see them as more extreme for the downwardly mobile (Parker and Kleiner, 1966). They all share the assumption, though, that the mobility experiences have direct effects—rather than modifying effects—on distress.

Although it has been important in earlier analysis of the selection-causation argument to consider the possible biasing effects due to mobility related stresses (Wheaton, 1978:386–7), we distinguish this sort of effects from those we are considering by examining both main and interaction effects of mobility and stress on psychological distress.

origins and health problems is highly significant, is due to the fact that origins are associated with emotional functioning primarily through association with response styles that modify the effects of some stresses on functioning. Origins determine beliefs, values, and behavior styles that exert lifelong influences on one's ability to deal with stress. These effects are indirect and, consequently, will not be detected clearly in analyses of main effects.

Some inferential support for this view exists in the data gathered about health care behavior. We speculated that upper status people who were born in the lower classes might retain part of their lower class health care behaviors, thus accounting for the continuing influence of origins on the HP–distress relationship. To examine this possibility, we focused on respondents who had not seen a physician for at least one year (virtually all those who had seen a physician in the year reported that they had a "personal physician," the variable of interest to us). We then looked only at people in the upper social strata. Of these, 80% of those born in the upper strata reported having a personal physician, but only 48% and 38% of those born in strata IV and V, respectively, reported having a personal physician. These differences are meaningful in statistical terms ($t = 1.99$ for the I–III vs. IV contrast; $t = 2.18$ for the I–III vs. V contrast). However, the smaller percentages among the upwardly mobile are not meaningfully different from those of people in the lower class strata, who vary (from 36% to 55%) in their probabilities of having a personal physician. Clearly, the upwardly mobile members of the upper strata have retained one important component of the health care practices characteristic of their lower class origins, thus accounting for the fact that their origins—but not their current social positions—have a modifying effect on the relationship between health problems and distress.

The literature on illness behavior clearly shows that socialization experiences of children born into lower class families can modify their interpretations of health problems. Lower class people have been shown to be particularly concerned about the possibility of becoming ill (Johnson and Ware, 1976), and to see themselves as particularly susceptible to illness (Ware and Karmos, 1976). Furthermore, this literature suggests that these concerns are modified by cultural factors (Mechanic, 1978:261–6).

There is good reason to believe that these differing interpretations of illness can create exaggerated emotional responsiveness to health problems. For instance, Zborowski (1952:28) argues that

> in Jewish families, where not only a slight sensation of pain but also each deviation from the child's normal behavior is looked upon as a sign of illness, the child is prone to acquire anxieties with regard to the meaning and significance of these manifestations.

Support for this general interpretation is found in Table 8, where we report HP × D(P_m or P_1) coefficients estimated separately in subgroups as part of the social origins interaction model. We hypothesized that meaningful specifications should be found across subsamples defining what we considered different cultural conditions in the families of origin, if the significant interaction in Table 7 is actually due to socialization experiences in the childhood of lower class respondents. As we see in Table 8, specifications of this sort do exist. Origins modify the influence of health problems on emotional functioning more among Jews than Protestants, more among Protestants than Catholics, and more among persons whose mothers were native-born than among those whose mothers were foreign-born. Clearly, some features of lower class childhood are important in making these people differentially respon-

sive to the emotional effects of illness in adulthood. These features apparently vary across certain cultural dimensions. And they are seemingly unaffected by the social positions achieved by these individuals as adults.

Discussion: We have not attempted to go far toward understanding the specific strengths that are important in helping one deal with stressful life events or with physical health problems. That was not our purpose here. Rather, we have attempted to make the case that social class differences in emotional distress are determined importantly by class differences in responsiveness to life problems. The data presented here clearly support this view, thus arguing against those who have focused exclusively on the differential exposure hypothesis of class differences. This latter hypothesis plays an important part, to be sure: Lower class people are exposed to more of the stressful events and situations that can lead to emotional distress than their middle and upper class counterparts. But we have argued, and demonstrated in our data, that a key part is also played by the fact that lower class people are more responsive emotionally to the stresses they experience, even when these stresses are no more common among them than among persons who occupy higher social positions.

Although we examined only two stresses, it is still clear that the modifiers associated with undesirable life events and physical health problems are quite distinct. This fact suggests that the resources that can be used to ameliorate distress vary from one problem situation to another. For instance, our results suggest that the resources available to people in socially advantaged positions do not modify the distress that can accompany undesirable life events. We suspect, though, that more careful analysis of subtypes of events would prove this statement more true of some events than of others.

Our analysis does not allow us to generalize about the specific types of problems that are reduced in their subjective stressfulness by the presence of objective resources, or about those that seem most highly influenced by social origins, or about those influenced by mobility processes. It would be valuable to know just what sort of problems these are and, in addition, to consider these in relation to the problems to which people in different class positions are equally responsive. In our own data, for instance, we found to our surprise that financial problems have very similar effects on the Gurin scores of respondents in the three social position subsamples. By itself, it is difficult to make sense of this absence of a differential impact when, on the face of it, it would seem that financial problems should have very different meanings for people whose access to broader financial resources varies. Our suspicion, though, is that this finding would take on more meaning if we were able to imbed it in the context of information about a wider variety of other problems—some of which have more damaging psychological effects on the poor than on the rich, some of which have comparable effects across class lines. The general analysis strategy used here provides a paradigm by means of which this type of information might be gained. We plan to pursue this line of research in our future work.

ACCESS TO INTERORGANIZATIONAL NETWORKS AS A PROFESSIONAL RESOURCE*

JON MILLER
University of Southern California

American Sociological Review 1980, Vol. 45 (June:479–496)

Six social service delivery systems for juvenile offenders were structured as interorganizational resource networks on the assumption that this would facilitate the development of a firm community base for their activities. The access that individual practitioners had to these program networks was seen theoretically as a measure of their integration into a larger social collectivity, a conceptualization that tied the analysis to a Durkheimian view of social structure. The specific hypothesis that was tested was that a strategic network position would be associated with more extensive professional ties to important institutions and decision-making centers in the surrounding community. In four of the six programs the hypothesis was confirmed; network centrality, measured sociometrically, was in fact a better predictor of the participants' community contact and community activism than their personal attributes, the technical resources and skills they brought to their work, or the formal status and autonomy they had achieved in the agency that employed them. In one of the two remaining programs, the hypothesis was not confirmed and, in the other, a reversal was evident: individuals with central network positions were less involved in the community than those who were relatively isolated from the network. The results are offered as evidence of how social network analysis can bridge levels of inquiry and provide new ways of approaching questions derived from traditional sociological theory.

INTRODUCTION

It is an established theme that organizations cannot be understood fully without evaluating the ways in which they deal with the interorganizational and community environments in which they are found (Aldrich, 1971; Aldrich and Pfeffer, 1975; Perrow, 1979). The surrounding context determines the resources and outlets that are available, and also the points of cooperation, conflict, and competition that must be dealt with. (For empirical treatments of these propositions see Simpson and Gully, 1962; Aiken, 1974; Yuchtman and Seashore, 1967; Seashore and Yuchtman, 1967; Aiken and Hage, 1968; Hall et al., 1977; Knoke and Rogers, 1978; Bick and Müller, 1978; Stern, 1979.)

This survey of service delivery systems adds a dimension to this viewpoint. The central proposition, derived from a Durkheimian view of social structure, is that the integration of an individual organization member into an interorganizational network of activity is a good predictor of other work-related behavior, including, in the present case, extensive professional involvement with the community in which the interorganizational system is embedded. Although the individual organization member has been kept as the focus of interest, the analysis actually cuts across five distinct levels of observation, represented in Figure 1. Information about the professional and personal attributes of individual practitioners (Level I) was supplemented with information about

their role in the agency by which they were employed (Level 2); their place in the interorganizational network of which their agency was a part (Level 3); their relations with specific organizations that were *not* included in this network (Level 4); and their active involvement, as professional practitioners, in attempts to influence the community decisions that were important for their clients (Level 5).

The respondents in the survey were the professional practitioners in six regional programs in a national project for the "deinstitutionalization" of "status offenders" (DSO). Because status offenders are problem youth whose offenses would not constitute legal offenses for adults, the objective of the project was to develop treatment alternatives that would not involve them in the official institutions of the juvenile justice system. To accomplish this, each DSO program (their origins will be described in more detail in the following section) was structured as a network of interacting, but formally independent, agencies. This strategy was based on the presumption that a member of one of the agencies in such a network would be able to draw on the other agencies in the network as a reservoir of helpful contacts, information and assistance, and that they would also be able to use their position in the network as a base from which to establish extensive professional ties to other key organizations outside the network itself, and as a vehicle for becoming actively involved in community decision making concerning the treatment of juveniles. In principle, then, a practitioner who was well connected within a DSO network would have an advantage in contributing to the development of a program with a firm community (as opposed to legal-institutional) base, an advantage that would be denied to an individual who was isolated or poorly placed within this network.

Together, the insistence by the funding source on multiagency networks as a service delivery mechanism and their emphasis on community-based services as a major program objective are an indication that the organization-to-organization and organization-to-community relationships that have long been of interest for organizational theorists have found their way into the central concerns of social service planners as well (on this point, see also Barth, 1963; Reid, 1964; Hasenfeld, 1972; Klein, 1976; Spergel, 1976; and Lincoln, 1979). In fact, in a rare instance of consistency between social practice and sociological theory, the rationale underlying the establishment of the DSO programs can be restated as a hypothesis: The more extensive the linkages that tie an individual into a functioning social network, the better situated the individual is to share in the benefits of that association and, therefore, to contribute to the objectives of the collective effort. Stated less abstractly and in the form in which it will be tested, the hypothesis is: The greater the involvement in a professional resource network, the greater the community involvement.

If we use "social integration" to refer to the extensiveness of the bonds tying individuals into a coherent social context, balanced, implicitly, against the fragmenting or individualistic forces that pull the individual away from the network, then the indebtedness of this basic argument to Durkheim (1952:208ff.) is apparent.[1] Taken literally, there is, of course, little resemblance between the contributions made to the "community-basedness" of a social program (which is our direct empirical concern) and the self-destructive behaviors that were Durkheim's immediate concern. However, the notion of social integration, to which we give empirical expression through the imagery of the social network, is sufficiently flexible as a theoretical construct to embrace a wide range of substantive interests.[2] Viewed in this light, much of the recent work on social networks—for example, works as diverse as Granovetter's (1974) study of personal networks in the search for employment, or Horwitz's (1977) work on the role of networks in the availability of mental health resources and, in the organizational literature, Blau's (1955) study of consultation patterns and structural effects (see also Rice and Mitchell, 1974)—can be seen as variations on a common theoretical theme. Before proceeding too far with this reasoning, however, there are countervailing arguments, to which we now turn, that suggest caution in applying this basic orientation to interorganizational problems.

As Turk (1973) has pointed out, relations among organizations are usually at least partially conflictive because the benefits of cooperation are counterbalanced by the necessity to compete for advantages and resources (see also Benson, 1975). In addition, Saranson et al. (1977) have argued forcefully, but less persuasively (given the thinness of their data), that interagency exchanges cemented primarily by money are counterproductive in the long run because the money nexus distracts attention and energy away from the proper performance of program activities.

In the case of the DSO project, these points are not without relevance. It is probable that some of the specific interagency linkages that were finally incorporated into the service delivery networks were entered into expediently by agency directors in order to qualify for the federal money. As a consequence, practitioners from different agencies were sometimes brought into interaction with each other without a clear-cut preexisting cooperative understanding and, in some instances, were required to participate in interagency activities and treatment practices that ran counter to their own professional philosophies. They then faced the problem of establishing the worth of their own approach to the problems of juveniles in the face of claims made by the other participating agencies in the network. In other words, the DSO programs were assembled in less than ideal circumstances. Agencies and individuals had much, potentially, to gain by participating in a network, but were asked to make sacrifices in return, not the least of which was the loss of autonomy—it was implicit in the agreement that they were to abide by the mandate imposed by a distant federal agency. Fry and Miller (1975) have pointed out that social experiments that are set into operation in such settings, even if they are intelligently staffed and generously funded, face built-in conflicts that can militate against success from the very beginning.

---

[1] Equally useful parallels could be drawn between contemporary social network analysis and other traditional theoretical formulations. Simmel (1955) is an obvious candidate for such an explanation.

[2] Drawing on Durkheim for insights into organizational activities is not entirely new. Blau (1977, chap. 8 and, especially, pp. 198ff.) for one, relies heavily on *The Division of Labor in Society* (Durkheim, 1933) in developing propositions about the division of labor and its correlations in work organizations. However, at the center of his discussion is a critique of the proposition that division of labor promotes solidarity, or social integration, through the mechanism of functional interdependence (social integration is defined approximately, as here, in terms of frequency of social contact). His argument is that functional interdependence need not imply interaction, particularly interaction between persons performing different (but complementary) functions in different organizations, who are usually also separated by social status differences. Whatever the validity of Blau's argument in some interorganizational contexts, it has little relevance in the present study, which is confined to a context in which the complementary functions of members in different agencies who were occupationally similar and more or less equal in status in fact did call for direct and indirect associations among them. In other words, it was precisely their functional interdependence in responding to the needs of clients that required their interaction. The question, then, is whether the effects of individuals' integration into a network of contacts at this interorganizational level could be traced out into their involvement with still other social contexts even further removed from the immediate workplace. Incidentally, Blau's assessment of the applicability of Durkheim to strictly *intra*-organizational problems has also been questioned (Lincoln and Miller, 1979).

On the other hand, Turk (1973) also reminds us that organizations, more than individuals, are able to balance the demands of conflict and cooperation by forming multiple linkages, sustained by different representatives for different kinds of interaction. In this way the value, on balance, of interorganizational ties may overshadow the circumstances in which they evolved. If so, then stable networks of exchange can continue to provide benefits even when a complete community of interest among the constituents does not exist. With this in mind, it is reasonable to take the hypothesis that we stated before as a point of reference. The mixed circumstances under which the DSO networks were established means that the hypothesis will have a fairly stringent test.

To assess the hypothesis properly, the effects of program participants' connections in these interagency networks must be compared with the effects of other variables that would also be expected to have an impact on their professional activities. Measures of training and experience are included in the analysis because they deal with the professional competence of program participants. Gender and race must also be accounted for because there is evidence that women and blacks work at a disadvantage in some organizational settings (Kluegel, 1978; Miller et al., 1975; Miller et al., 1980; Miller and Ransford, 1978), a fact that could influence their ability to form alliances both within the network and with important actors outside it. There is also evidence that official organizational rank may be a key to extensive interorganizational ties and linkages to the larger community (Blau, 1977:199; Perucci and Pilisuk, 1970). However, it has also been noted that most organization members of high and low status function as outside representatives, whether or not this is explicitly spelled out for them by the organization (Haas and Drabeck, 1973:220ff.; see also Evan, 1976). This was the case in the DSO programs; practitioners at all levels were expected to interact with agencies and institutions outside their own work settings. Therefore, to find a strong positive effect of status on community ties and community activism would indicate that this expectation was being violated. This possibility, alone, provided a reason to take this variable into account. Finally, in all of the programs, rank and file participation in decision making was the dominant and legitimate pattern.[3] Whether this also facilitated performance in community-based activities is a question that needs to be asked. Evidence to date concerning participation and performance has been quite mixed; this is apparent when we compare the critical review of Strauss and Rosenstein (1970) with a more recent and quite strongly argued study by Pennings (1976).

THE RESEARCH SETTING

The DSO project was put into operation in the spring of 1976 by an agency of the U.S. Department of Justice. Seven programs that submitted acceptable proposals were included in this survey,[4] which took place from six to nine months after the programs were funded and in operation. However, in one program a questionnaire that did not include any measures of network participation had to be used and, for this reason, a full test of the hypothesis was possible only in the remaining six. The two aspects of the programs of most interest here are their network structures and the mandate imposed upon them by the funding source that called for two different kinds of community-based activity. These will be discussed in turn.

---

[3] A large majority of both supervisors and supervisees in all programs reported a participatory decision-making arrangement that involved a great deal of discussion. Both groups also rated the quality of the supervisor/supervisee relationship favorably (means around seven on a nine-point scale). Fewer than 10% in either category expressed a desire for less participatory styles of decision making.

[4] Actually, eight programs shared the approximately $12 million allocated for the national DSO program. However, one of these was delayed in starting for several months and had to be excluded entirely from this survey. The remaining programs were widely dispersed, with two in the Northwest, one in the Far West, and one each in the Southwest, Midwest, Northeast and Southeast.

The Network Structure of the Programs

In each of the DSO programs, the grantee agency, which became the fiscal and administrative center, was required to establish and oversee an interagency service delivery "system," or network, as a way of bringing previously dispersed and autonomous service delivery resources in the community together into a coordinated joint enterprise. The agencies that were brought into these networks had to agree to function as part of such an effort in order to receive their share of the grant funds.

Among the funded projects, one relied almost exclusively on private agencies, two relied primarily on linkages among public agencies, and the others brought together a mixture of public and private agencies. Each program provided us with a roster of participating organizations so that the boundaries of the networks at the time of the survey could be accurately established. Within these boundaries, the separate agencies shared one common source of funding, a common set of official goals, a common "client" pool, and a common relationship to the organization occupying the recognized administrative center of the program. They also occupied complementary positions in an interagency division of labor and, therefore, were bound together to some extent by reciprocal obligations. For these reasons, the agencies in the networks were clearly set off from those that remained outside the networks.

In two of the programs, a network of agencies for dealing with juvenile offenders in general, not just status offenders, was already in place before the DSO funding began. The directors overseeing these established networks based their applications for DSO funding on the claim that status offenders could be dealt with as a clearly delineated category through their existing interagency mechanisms. In all the other programs, the networks were assembled largely de novo, specifically for the DSO project. This distinction will be important later in the interpretation of the findings.

The Mandate for Community Involvement

Because of the stress on treatment alternatives with a broad community support base, a matter of both theoretical and practical concern was the relationship between the network of agencies in a given program and the police, courts, schools, churches, and other public and private agencies that remained outside the DSO network, per se. In principle, by being part of the network, individual practitioners would have more knowledge of (and more points of access to) this larger circle of organizations. Their own direct contacts with these outside organizations would be multiplied by the shared pool of contacts that would then become accessible through interaction with other members of the network.

The second, and equally important, component of the mandate for community involvement was the expectation that the network participants would be active in attempts to influence the development and application of local treatment policies and in efforts to raise the level of support from the community as a whole for juvenile programs. In other words, it was expected that they would be active advocates (see Coates, 1974), engaged in efforts to change the climate of response in the community to the problems of status offenders.

METHODS AND MEASURES

The number of agencies involved in the DSO project ranged from seven in the smallest program to 25 in the largest, with a total of 88 agencies overall. Typically, the agencies were small and, because they had other obligations (for example, continuing to deal with juvenile offenders who were not categorized as status offenders), they sometimes assigned only a subset of their members to the DSO network. As a result, the number of subjects for the survey, 522, was not large. Of this number 350 (67%) responded.

A separate regression analysis was performed for each of the programs and the results are presented as a series of independent replications. This approach was selected because it preserves the distinctions among the programs so that the differing circumstances under which they were established can be highlighted.[5] No direct comparisons of standardized regression coefficients between programs are intended; rather, the approach is to assess the overall configuration of findings from one program to another. Analytically, the data cut across the five distinct levels indicated in Figure 1. The measurement of variables from each of these levels will now be described, beginning with the dependent variables, the two dimensions of community involvement (Levels 4 and 5).

Community Involvement: CONTACT and ACTIVISM

Six questions in the survey measured the respondents' contact, in their capacity as DSO practitioners, with law enforcement agencies, schools, churches, courts, and public and private social service agencies that remained outside the interagency DSO program. The correlations among the measures were all positive (see Appendix A), and the alpha reliability coefficient for an index based on their sum (referred to as CONTACT) was .74.[6] The format of the questions, which had seven response categories ranging from "never" to "almost constantly," is given by this example:

"In the course of your work for the DSO program, how often do you come into contact with (members of local police and/or sheriff's departments)?"

Another four items registered the respondents' professional activism in the larger community by asking how often in the course of their work for the DSO program they were involved in efforts to get more local economic support for programs for juveniles; efforts to get more community organizations involved in the problems of juveniles; attempts to influence local policies on the ways the problems of juveniles are handled; and attempts to get better local treatment resources for the problems of juveniles. These four items, which were also positively intercorrelated (Appendix A), were combined into an ACTIVISM index with a reliability coefficient of .88. (The means and standard deviations for these two community involvement indexes are given in Appendix B.)

Network Variables

The connectedness of interorganizational fields has been assessed in a variety of ways. In Turk's approach (Turk, 1970; 1973) interorganizational exchanges are inferred from the functional and spatial division of labor that is known to exist among a set of organizational actors. A different approach is represented by measures based on the existence of joint programs (Aiken and Hage, 1968; Hall et al., 1977) and a third method is emerging from sociometric network analysis, an approach that assesses interorganizational ties through the linkages that exist among the members of formally discrete organizational units (Anderson, 1967; Rogers, 1974; Knoke and Rogers, 1978).

The method used here is a variant of this third approach. Our concern was to locate individuals in the overall mesh of interpersonal connections that linked together the different agencies constituting a given DSO program. These linkages were established from reports of closest WORK CONTACTS and four other sociometric dimensions, including INFLUENCE (who determines how the work of the program is done); RESPECT (whose professional opinion is most highly regarded); informal SUPPORT (who is dependable in times of crisis); and professional ASSISTANCE (who is a good source of professional advice).[7] For these items, respondents were instructed to report on their relations with others throughout the interagency service delivery system rather than to confine their choices just to members of their own agency. Nominations that were, in fact, interagency as opposed to intraagency ranged from 36% to 60% on the work contacts criterion, with similar proportions on the other four sociometric items. In each of the programs, virtually every respondent was tied, through a varying number of intermediate links, to every other participant in the interagency network. For this reason, but also because the interagency network itself was the operating unit and, therefore, the focus of our attention, we have not separated intra- and interagency connections in the analysis.

---

[5] An alternative, which we elected not to pursue in this presentation, would involve a pooling of the data from the different programs, with dummy variables and interaction terms introduced to assess the effect of program site on the relationships of interest.

[6] This index was constructed to simplify and condense an otherwise unwieldy analysis. Separate regressions for each of the six items in the scale (not shown) produced results that did not depart substantially from the results reported for the index. In addition to recording the frequency of their contacts with organizations outside the network, respondents were also asked to rate those contacts in terms of the level of cooperation and the level of client benefit produced. In all the programs these evaluations were clearly favorable: means ranged from 6 to 8 on nine-point scales. Therefore, it is assumed throughout the analysis that extensive contact with outside agencies represented a positive contribution to program goals.

In processing the WORK CONTACTS data, a measure of individual Centrality was employed (Shaw, 1964; Harary et al., 1965) that indexes the number of links that must be crossed in order for a given individual to be reached by every other person in the network. It, thus, reflects both the direct (A-B) and indirect (A-B-C-D) paths, and their lengths, that tie a participant into a network; a highly central individual is one who is tied to others in the network by a large number of short distance connections.[8] The properties of the network and the positions of individuals in it are derived from the matrix of choices exercised by all the respondents. The structure of interaction and communication thus revealed is clearly a "social fact," to borrow again from Durkheim (1938: lvi; 12) and the measure of an individual's Centrality in the network is a relational property (Lazarsfeld and Menzel in Etzioni, 1961) for which the respondent, alone, should not be expected to be a completely reliable informant, since it is based on a collective judgment.

The official rosters of participating agencies prepared for us by the program administrators made it possible to specify the boundaries of the DSO networks with some certainty. The Centrality measures thus refer to individuals' locations within clearly defined and circumscribed multiagency fields. It is important to note that the items comprising the measure of community CONTACT (one of the two dependent variables described above) were deliberately phrased to deal with contacts developed with organizations outside this field and, therefore, represent a distinct sphere, or level, of activity. Thus, both Centrality and CONTACT tap interorganizational relationships sustained by individuals, but they are defined and measured independently and, therefore, can stand in the logical relation of independent to dependent variable (centrality in the network facilitates contact in the community) without becoming tautologically intertwined.

---

[7] The sociometric questions we used asked the respondents for a fixed number (three) of nominations, a method which, though it has important recent precedents (Laumann and Pappi, 1976; Burt, 1977), has also been criticized (Holland and Leinhardt, 1973). The rationale of the forced choice format is to confront respondents with a standard stimulus, and to minimize the reporting of ties that might be unimportant. A criticism is that this method is subject to error because of underreporting (or more rarely, overreporting) and, thus, may produce an inadequate picture of the density of the overall network. In the present case, however, no participant in any of the networks was excluded by the method we used (that is, neither chose nor was chosen), and we are confident that the basic structure of the networks was accurately captured. However, we agree that the open-ended format is preferable for most organizational and interorganizational applications.

[8] The Centrality data were generated by a program for DIGRAPH analysis generously furnished to us by Peter Marsden. Statistical properties of the index are also discussed by Shaw (1964). Another application of this measure to organizational data appears in Rice and Mitchell (1974). The Centrality index that we used is highly correlated with other, simpler, sociometric scores—in particular, the simple sum of choices received from others, but, because it includes information on indirect ties, it provides a more sensitive gauge of individuals' access to channels of communication and interaction.

Freeman (1977) has described an alternative measure of network centrality based on "betweenness," or the frequency with which an individual's position allows him or her to mediate the connections among other participants in the network. It should be very useful for isolating exchange "brokers" in a network, but this was not our objective. Rather, we were concerned with the extent to which individuals had access to, not control over, manifold others and for this purpose the Centrality index we employed is preferable.

The remaining four sociometric items were processed in much the same manner as the measure of WORK CONTACTS, but note that the "networks" derived from these items are not based on actual interaction. Rather, they comprise a collective representation of how INFLUENCE, RESPECT, MUTUAL SUPPORT, and ASSISTANCE were distributed among the participants. In fact, the responses based on these items largely replicated the WORK CONTACTS and, as a result, the five network measures are highly intercorrelated (Appendix A).[9] In the regression analysis, it was not possible to separate their effects on CONTACT and ACTIVISM with any confidence. For this reason, they were entered separately into the analysis, but a single Beta (a "sheaf coefficient") was computed, according to the method proposed by Heise (1972), to record their joint impact on the dependent variables. This method is preferable to combining the five measures into a single index and we believe it is also superior to simply choosing one measure and excluding the others from the analysis. However, inspection of preliminary results based on all three of these approaches showed that the substantive conclusions, in fact, would be quite similar. Only one set of results is reported.

Intraorganizational Variables

The organizations brought into the DSO networks were generally quite "flat" in their internal hierarchies; consequently, organizational STATUS refers to the dichotomy, supervisor/nonsupervisor. Ability to participate in the organizational decision-making process, PARTICIPATION, was measured by a dummy variable based on an item (taken in slightly altered form from George Miller [1967]) that records whether respondents were involved in participative, directive or laissez faire relationships with their supervisors.

Individual Resources and Attributes

At this level, four variables were entered into the analysis. GENDER and RACE were dummy coded. EXPERIENCE refers to the number of years the individual had worked at his or her occupation, and EDUCATION to the number of years of formal schooling reported. A measure of tenure was excluded because of the brief history of the DSO programs.

FINDINGS

The results fall into two distinct patterns, one supporting the hypothesis and the other questioning it. The prediction that network location has a positive impact on the level of practitioners' contact with non-DSO organizations and on their activism in the community at large received substantial support in the programs numbered one to four in Table 1. However, very different configurations appeared in Programs Five and Six, which were the two programs that had added the processing of DSO clients to the activities of ongoing service delivery networks. These disparate findings will be discussed in turn.[10]

Results Supporting the Hypothesis

In the first four programs, the net effect of integration into the interagency networks explained from about 11% to almost 60% of the variance in CONTACT

---

[9] Note also in Appendix A that, within each program, the five different network measures showed quite similar patterns of relationships to the two dependent variables, CONTACT and ACTIVISM. The implication is that there actually was a single network of interaction that served a number of different functions for the participants in these programs.

[10] The data for the seventh program, for which no network data were available, are also displayed in Table 1. Without the Centrality measures the explained variance for CONTACT and ACTIVISM (8% and 17%, respectively) was substantially smaller than that reported for the other six programs.

Table 1. Regression of Community Contact and Community Activism on Individual Resources, Organizational Position and Network Location, for Seven Interagency Programs Involved in the Deinstitutionalization of Status Offenders (DSO)

	Program One (N=76)		Program Two (N=37)		Program Three (N=36)		Program Four (N=20)		Program Five (N=57)		Program Six (N=35)		Program Seven (N=89)	
Individual Resources:	CONTACT	ACTIVISM	CONTACT	ACTIVISM	CONTACT	ACTIVISM	CONTACT	ACTIVISM	CONTACT	ACTIVISM	CONTACT	ACTIVISM	CONTACT	ACTIVISM

Cell entries are standardized regression coefficients.

* $p<.10$, ** $p<.05$, *** $p<.01$.

[a] All respondents in this program were white.

[b] Network measures not available in this program.

[c] Sheaf coefficient computed from betas for five centrality measures: WORK CONTACTS, INFLUENCE, RESPECT, SUPPORT, and ASSISTANCE.

and sometimes smaller, but still appreciable, proportions of the variance in ACTIVISM. The impact of Network Centrality was generally greater than any other factor and more consistent than all of the individual- or organization-level variables, with the partial exception of RACE. (Overall, being white was a handicap for community involvement, judging from the consistently negative, if not pronounced, relationships between RACE and the two dependent variables.) By comparison, the effects of the remaining variables, GENDER, EXPERIENCE, EDUCATION, STATUS and PARTICIPATION, were scattered and inconsistent. The dominant impression, therefore, is that the practitioners' locations in the networks of professional exchange that knit these programs together were more consequential for their activities outside the network boundaries than were the ascribed attributes and technical resources they brought to their work or the position or autonomy they had attained within their own agency.

For purposes of interpretation, it is useful to note that (based on the overall configurations displayed by their networks) two different administrative strategies of interagency coordination were represented among these four programs. A detailed examination (not shown here) of the sociometric data revealed that, in Programs One and Two, the grantee agency responsible for administrative coordination frequently served as intermediary for the contacts that took place between one agency and another in the program. In general, the administrators adopted a fairly formalistic or bureaucratic approach to overall program coordination as a way of shaping the network to conform to program priorities. Programs Three and Four by comparison were more personalistic; members of the central administrative agency were by no means inaccessible, but practitioners in the separate agencies also had a great deal of direct, unmediated contact with each other.[11] In other words, while all four programs displayed coherent network structures, in Programs One and Two, Network Centrality was characteristic of practitioners who were strategically placed within a formally articulated system of exchanges, while in Programs Three and Four, Centrality describes a person well-integrated into a more loosely coordinated network of comparatively less formalized exchanges. This indicates that quite different strategies of interorganizational coordination can accompany similar outcomes; the critical factor for the practitioner was to be favorably located in the exchange apparatus, whatever the shape of that apparatus might have been. However, judging from the differences in explained variance in CONTACT, the advantage of network integration was more pronounced in the two less formalized programs. This accords well with the notion of professional autonomy, which is defined, in part, by the freedom to select one's working relationships with colleagues, and it suggests a direction that might be taken in exploring how professionals interact with various "audiences" and "publics" that are important to their professional standing (Haug and Sussman, 1969; Grimm and Kronus, 1973; Blankenship, 1973).[12]

---

[11] This descriptive information on the programs is presented in detail in Miller (1978) and will not be duplicated here. The descriptions of the networks as formalistic or personalistic were substantiated by visual plots based on a smallest space analysis of the sociometric data, and by field observations and interviews with key participants. The smallest space analysis plots for Programs One and Two revealed clear "radial" or "core-periphery" patterns; ties between individuals in different agencies were channeled through the administrative center. This indicates an active effort to shape the communication channels by those in positions of responsibility for the network as a whole. This was less in evidence in Programs Three and Four. These SSA plots are available upon request.

[12] Our predominant concern has been the advantage of network centrality for community involvement. However, a subsidiary analysis explored the effects of Centrality on an index based on participants' subjective evaluations of the effectiveness of the program and their own role within it (Miller, 1978). In the two "formalistic" programs, Centrality bore little relationship to this index; it accounted for 4% of the variance in Program One and 7% of the variance in Program Two. In the two "personalistic" programs the explained variance rose to 42% in Program Three and 27% in Program Four. For comparison, in Programs Five and Six the network construct accounted for, respectively, 10% and 20% of the variance in participants' subjective estimates of effectiveness.

Results Questioning the Hypothesis

The data for Programs Five and Six do not follow a similar pattern. Here, it was clearly not the well-integrated individuals who were accounting for community-based activities but, at the same time, in neither of these two programs was the average level of CONTACT or ACTIVISM low (see Appendix B). In Program Five, all of the predictor variables combined explained only 18% of the variance in community CONTACT. Of this total, the largest increment, about 5%, was accounted for by network location, but the effect was negative (Beta = −.45). For ACTIVISM the total explained variation was greater (34%), but the network increment to the R^2, while positive, was quite small (only about 2%). We have already pointed out that there was a network of interagency connections in both of these programs before the DSO funding began. It is also significant that in Program Five many of the agencies in the network were involved in other, non-DSO programs for juvenile offenders (to which we had no access) and were answerable to a variety of state, local and federal sources, many of which also stressed the desirability of community-based activities. As a result, they were tied into multiple networks in a way that was not characteristic of the other DSO programs. The likelihood that community-based activities were already well established in these agencies before the DSO mandate was added may have obviated any additional advantage to be gained from establishing a new set of linkages among the agencies officially engaged in the DSO program. This ex post facto interpretation is plausible, if speculative, but it stresses a fundamental difference between this program and the others that we were unable to document in sufficient detail. It is not intended to obscure the fact that the prediction we made for this program was essentially incorrect: Network Centrality was of quite limited usefulness in accounting for community involvement.

No such explanation would account for the data for Program Six, where the clearly *negative* impact of Centrality accounted for 15% of the variance in CONTACT and 18% of the variance in ACTIVISM. Those who were relatively isolated from the network of professional exchange, or who, perhaps, were able to avoid it, were represented more often in ties to the community than those who were integrated into the network.[13] It is interesting that these are the only results that are consistent with Granovetter's argument that weak ties to social networks facilitate outside linkages (Granovetter, 1973). In this program, as in Program Five, the federal DSO funds were also used to supplement the budget of an existing state-run juvenile service delivery system, but there was not the same multiplicity of mandates and funding sources. It is apparent that a viable interagency network did, in fact, exist in this program (51% of all sociometric work contacts were exchanged by the members of different agencies), and the level of its community-based activities was not low compared to the other programs. But the fact that less involvement in the interagency network meant more involvement in the community suggests a division of labor that was not anticipated, either by the funding source or by the hypothesis with which we began. The analysis in Table 1 indicates that the community-based activities had devolved somewhat disproportionately upon the better educated but less experienced personnel in the program, suggesting that being freed from extensive interagency ties may have been, for some of them, a prerequisite for taking on this important function. Conversely, as one anonymous reader has suggested (following the reasons of Granovetter), it may have been that the more experienced members had interpersonal ties within the program that were stronger, if not more numerous, and that this inhibited their outreach to the community.

Without additional data, it is not clear exactly why such a division of labor between those central to the network and those relatively isolated from it evolved, especially since this division of effort was inconsistent with the reasoning that persuaded the funding source to call for interagency efforts. Since Centrality did not promote community involvement, what its advantage in the interagency network actually was is also left unexplained, though the division of activities between more and less experienced personnel, suggested before, implies the operation of a separate set of goals for those who were closely tied into the interagency network. One possibility that has been suggested[14] is that this already-established network might have been able to delegate the new community liaison activities demanded by the DSO funding source to the periphery, thus allowing the core (central) members to continue to concentrate on directly client-related activities. By contrast, in the newly forming networks (Programs One through Four) all the members were expected to deal with both sets of tasks and in such a situation a strategic network location was a definite advantage in forging links to the community. This suggestion raises some interesting possibilities because it implies that, over time, organization-to-organization and organization-to-community ties in service delivery systems may be shifted from one category of members to another, with the result that an increasingly complicated division of labor becomes visible as networks age. This in turn prompts another question about how the uses made of an interorganizational network may be subject to manipulation by different interest groups represented in the system.

---

[13] This negative relationship removes any doubt that the connection between Centrality and CONTACT may be tautological.

DISCUSSION

Summary and Implications

The programs we surveyed involved agencies bound together by professional exchanges among their members and these interagency networks were, in turn, embedded in larger multiorganizational fields. The hypothesis we examined specified that the involvement of organization members in this larger interorganizational and community environment was directly affected by their integration into the interagency structures of professional exchange, over and above the advantages that might have been gained from their own individual resources and from their positions in the status hierarchies of the specific agencies that employed them. The hypothesis was confirmed in four of the six cases examined: integration into patterns of organized activity at the interagency level was predictive of involvement in collective action at two other, more encompassing levels. In a fifth case, the hypothesis was not confirmed, and in a sixth replication, the results were the reverse of what was expected. The reasonable conclusion is that integration into a comprehensive professional network can serve as the base for developing external community linkages but with the qualification that this is not the only mechanism through which such community involvement is realized. There are alternative means for achieving this objective that we were unable to illuminate beyond the suggestion that they are directly related to the age of the network, the multiplicity—and probably order of precedence—of program goals, and the developing internal division of labor among the constituent organizations and participants, all factors that are best examined from a longitudinal, possibly evolutionary, perspective.

The parallel we drew between the multiplicity of individuals' direct and indirect ties to interorganizational networks, on one hand, and the concept of social integration, on the other, reflects our reliance on a Durkheimian framework. In *Suicide* (Durkheim, 1952), social integration was discussed in a way that could be applied to several levels of analysis. In fact, it figured in the explanation of reactions to stress in two ways: tightly integrated collectivities have low suicide rates *and* isolated individuals are more likely to commit suicide. The concept thus had both a social-structural and a social-psychological usage. In *The Division of Labor in Society* (Durkheim, 1933), a closely allied concept, solidarity, played a comparable role in the characterization of entire societies. The common idea in these otherwise different treatments was the notion of interconnecting and overlapping bonds, of various sort, that link together the parts of social systems, whether the parts are individuals or collectivities. This is a notion that finds a direct analog in the concept of social network, which also bridges many levels of sociological investigation (Granovetter, 1973; Alba and Kadushin, 1976).

---

[14] By Rolf Ziegler, University of Munich, personal communication.

There is already a strong conceptual thread in the organizational literature formed by questions involving the nature of social ties; a thread that connects studies conducted at several different levels of analysis, from studies of interpersonal relations (Blau, 1962; Katz and Kahn, 1978:602ff.); through studies of work group cohesion (Seashore, 1954); intraorganizational structure (Rice and Mitchell, 1974; Rogers and Agarwala-Rogers, 1976); interorganizational connections (Levine, 1972; Rogers, 1974; Hall el al., 1977; Bick and Miller, 1978); and organization-community relations (Turk, 1973). Moreover, thinking in terms of networks provides a common conceptual ground not just among such studies in organizational analysis, but also between them and investigations in other substantive areas, ranging from the study of friendship groups (Granovetter, 1973), to the study of communities (Laumann and Pappi, 1976; Craven and Wellman, 1973), national elites (Moore, 1979) and international systems (Snyder and Kick, 1979). The specific interests and theoretical underpinnings of research conducted in these different areas have been quite varied, but in all of them the idea of integration into networks of social ties can be brought forward and, at one level of abstraction, they can be seen to be asking a similar question in different forms. Such a diffusion of common theoretical formulations and methods within and between specialties will mean less balkanization within organizational sociology and less pronounced segregation between it and the rest of the field.

Conclusion

In weighing these findings it is essential to keep in mind the environments in which the DSO programs were established. The agencies involved were generally small, democratic, reliant upon a highly specialized work force and chronically short of resources. They were called upon to create community-based solutions for the problems of troublesome young people (themselves, members of an ambiguous category) but, beyond the requirement that these solutions be implemented by "interagency systems," very few explicit guidelines as to how they should be structured were offered, and the assembling of the programs took place in a fashion that differed from one site to another. Thinking practically, this environmental turbulence and uncertainty could militate against program success and, thinking in terms of research and theory, it could militate against clear-cut findings because of the likelihood that, given the pressure of time and the lure of fast federal money, antagonists and competitors and philosophical opposites were sometimes drawn into the same networks. Therefore, conflict over resources and strategies could be exacerbated and the necessity of maintaining a network position simply to guarantee the flow of funds could become as much a liability as an asset for effective performance. The idea that location near the center of such an interagency network would function as a professional resource for practitioners in their attempts to forge cooperative, program-relevant ties to the larger community would seem to have a fairly stringent test in such unsettled circumstances, and we expect that the patterns we observed in four out of six programs will recur frequently in future replications.

RESEARCH NOTE

BEYOND MISSPECIFICATION IN SOCIOLOGICAL ANALYSES OF INCOME INEQUALITY *

ERICH WEEDE
University of Cologne, West Germany

American Sociological Review 1980, Vol. 45 (June:497–501)

Since the mid-70s, there has been some debate in the *ASR* about correlates of the size distribution of income in cross-national analysis. According to previous research, economic development seems to have little impact, whereas state strength or dependency, and democracy are more useful predictors of income inequality. Here it is argued that much sociological research rests on misspecification of the relationship between economic development and income inequality, and therefore needs reanalysis rather than uncritical acceptance. A partial reanalysis of previous studies, avoiding specification error, first demonstrates a moderately strong curvilinear relationship between economic development and inequality; second, it casts considerable doubt on state strength or little dependency as equalizers of income; third, it reconfirms a cross-sectional correlation between democracy and less inequality, even after proper controls for economic development.

Recently, there has been much interest in determinants (or cross-sectional correlates) of the size distribution of income. Economists and econometricians generally agree that the size distribution of income is a curvilinear function of the level of economic development, as has been suggested by Kuznets (1963; 1976) and empirically supported by Ahluwalia (1976), Chenery and Syrquin (1975), and Paukert (1973). Income inequality is fairly moderate at extremely low levels of economic development, reaches a maximum at intermediate levels of development, and finally decreases. The specification of the relationship used by Ahluwalia (1976) or by Chenery and Syrquin (1975) is a quadratic polynomial regression of inequality on economic development, after indicators of the latter have been logarithmically transformed, for example:

$$\text{Gini income distribution} = b_0 + b_1 (\ln \text{GNPC}) + b_2 (\ln \text{GNPC})^2 + E. \quad (1)$$

Research published in the *ASR* (Rubinson, 1976; Rubinson and Quinlan, 1977; Stack, 1978) argues that state strength variables—such as high government revenue to GDP or low trade to GDP ratios—or democracy are more powerful independent variables than is the level of economic development. However, such results rest on misspecification of the relationship between economic development and income inequality. While Rubinson (1976) or Rubinson and Quinlan (1977) regressed indicators of inequality on the logarithm of energy consumption per capita, Stack (1978) preferred gross domestic product per capita. None of them ever tried second order polynomial regression. The purposes of this research note are, first, to demonstrate the superiority of the economist's specification over other specifications, and second, a reconsideration of the effects of state strength and, to a much lesser degree, of democracy on the size distribution of income.

As this note is a critique of the work done by Rubinson (1976), Rubinson and Quinlan (1977), and Stack (1978), I work with the same sample of 47 nations as Rubinson (1976:657) does. Rubinson and Quinlan (1977), as well as Stack (1978),

I would like to thank Bernd Scheuvens and Horst Tiefenbach for their assistance in producing this research note.

rely on subsamples. Moreover, I take quintile shares of personal income and Gini *circa* 1965 from Paukert (1973:114–5), again as was done in the work considered here. In accordance with Rubinson (1976) or Rubinson and Quinlan (1977) energy consumption per capita (ENPC) is chosen as indicator of economic development. My data source is Taylor and Hudson (1972:326–8).

As Table 1 demonstrates, the econometric or "proper" specification of the relationship between economic development and income shares or Gini is consistently superior to other specifications. Moreover, using ln ENPC only as a linear predictor of income inequality, as Rubinson (1976) and Rubinson and Quinlan (1977) did, is a particularly poor specification. This specification comes out worst from a fit point of view in 5 out of 6 equations. Neither adjusting percentages of variance explained for differences in degrees of freedom between equations nor substitution of GNPC for ENPC affects this conclusion (Weede and Tiefenbach, n.d.). Therefore, there is ample reason not to accept uncritically results concerning the beneficial impact of strong states produced by Rubinson (1976), but instead to test whether they survive respecification of the relationship between economic development and inequality.

From among his indicators of state strength, I chose only two, that is, government revenue as a percent of GDP for domestic state strength (or for state control of domestic economic activities), and trade as a percent of GNP for state strength vis-à-vis the international environment. Admittedly, this selection of independent variables has been influenced by the availability of data. Nevertheless, it is also defensible by other arguments. First, government revenue as a percentage of GDP is used in most regressions reported by Rubinson (1976) or by Rubinson and Quinlan (1977), while other independent variables play a much less central role. Second, imports and exports as a percentage of GDP had extremely similar effects on indicators of inequality in Rubinson's work (1976:654). Stack (1978:271), too, noted that both of them are related to inequality. Therefore, it seems plausible to combine imports and exports. The substitution of trade as a percentage of GNP for trade as a percentage of GDP is a matter of convenience which should not make much difference. While such a selective attitude towards independent variables used in the research considered here prohibits a recalculation of each and every detail, it should suffice to evaluate the merit of the central conclusions. Moreover, given 47 observations—sometimes less, due to missing values—it makes little sense to use too many independent variables.

There is one important detail where my design parts company with Rubinson's (1976) and with Rubinson and Quinlan's (1977). They time-matched independent variables and inequality data and therefore had to include the year as an independent variable. While such a strategy is not without merit, it is not the standard solution either. World Bank econometricians Ahluwalia (1976), and Chenery and Syrquin (1975) preferred to match the inequality data of *circa* 1965 with the independent variables for 1965, or the closest year available, in spite of the fact that the time-spread for inequality data is somewhat wider than for other variables. As I see the costs of doing it in Rubinson's way much more clearly than the benefits to be derived therefrom, I took *circa* 1965 data

Table 1. Percentages of Variance Explained in Income Shares or Gini by Economic Development under Different Specifications (N=47)

	Q_1 bottom 20%	Q_2	Q_3	Q_4	Q_5 top 20%	Gini
Energy Consumption per Capita (ENPC)	2.4	10.0	32.4	30.2	21.8	12.3
ln ENPC	9.3	2.9	21.9	20.6	10.4	3.9
ENPC, ENPC^2	7.0	10.1	35.6	35.9	22.8	12.3*
ln ENPC, $(\ln \text{ENPC})^2$	12.5	14.5	38.0	40.0	30.1	18.6

* Where the F-level was insufficient to warrant inclusion of ENPC^2 in this equation.

Table 2. State Strength as a Determinant of Inequality under Proper Specification (N=43)

	Q_1 bottom 20%	Q_2	Q_3	Q_4	Q_5 top 20%	Gini
ln Energy Consumption Per Capita Expressed in Kilograms of Coal	−1.27	−2.33	−4.25	−6.67	+14.30	+0.11
Equivalents (ln ENPC)	0.39	0.19	0.04	0.01	0.02	0.09
(ln ENPC)²	+0.058	+0.18	+0.41	+0.65	−1.27	−0.0094
	0.65	0.24	0.02	0.00	0.02	0.10
Beta Weight of b_1 (ln ENPC) + b_2 (ln ENPC)²	0.47	0.22	0.47	0.68	0.42	0.27
Government Revenue as	+0.035	+0.082	+0.056	−0.038	−0.13	−0.0022
a % of GDP	0.51	0.21	0.45	0.64	0.54	0.37
	+0.15	+0.30	+0.15	−0.09	−0.13	−0.21
Trade as a % of GNP	−0.019	−0.026	−0.026	−0.027	+0.099	+0.0011
	0.25	0.20	0.25	0.29	0.14	0.14
	−0.19	−0.21	−0.16	−0.14	+0.22	+0.24
Adjusted Percentage of Variance Explained	10	6	30	36	22	10
Percentage of Variance Explained	18	15	36	42	29	19

Where first cell entries are unstandardized coefficients, second cell entries are significance levels, and third cell entries are standardized coefficients (beta weights).

for government revenue as a percentage of GDP from Chenery and Syrquin (1975:188–91), and trade as a percentage of GNP from Taylor and Hudson (1972:372–7). My intention to do without time-matching also derives from Rubinson's report that time is insignificant when a time variable is included in the regressions after time-matching. Unfortunately, Chenery and Syrquin (1975) do not report government revenue for four nations which are part of my sample. I took this as an implicit but negative comment on availability, reliability, or comparability of those data and accepted the corresponding loss of four observations.[1]

Any deviation from Rubinson's (1976) design is a possible source of different results. Therefore, I first reproduced the major results of Rubinson, using his specifications with my somewhat different data set. As I could by and large do so, it makes sense to rule out differences in time-matching, data-sources, or number of cases as determinants of different solutions. Table 2 reports the impact of state strength and economic development on income inequality under proper specification.

If one compares the last rows of Tables 1 and 2, one finds that percentages of variance explained by economic development alone (in proper specification) are nearly as high as those explained by economic development *and* state strength. Because of the minor difference in the number of observations, economic development alone can do even better in two equations of Table 1 than economic development plus state strength do in Table 2. Therefore, state strength, as indicated by high government revenue/GDP and low trade/GNP, seems to have little impact. This suspicion is confirmed when we look at the significance levels[2] of regression coefficients. Rubinson's (1976) master indicator of state strength, that is, government revenue as a percentage of GDP, never comes even close to 10% significance. While domestic state strength makes little difference, state strength vis-à-vis the international environment has more impact. At least coefficients come close to significance at the 10% level in 2 out of 6 equations. Although even trade as a percentage of GNP performs quite poorly in Table 2, believers in dependence theories may point to foreign trade dependence increasing inequality by adding to the share of the top quintile and subtracting from the shares of all other income groups.

---

[1] The nations are: Argentina, El Salvador, Gabon, and the United States.

[2] In cross-national analysis, we almost never work with random samples. Therefore, no strong argument for use of significance levels can be made. Nevertheless, they are conventionally used for lack of a better alternative.

Economic development performs as it should for the third, fourth, and fifth quintiles, as well as for Gini. Coefficients for both the simple and the squared terms are significant at the 10% level, but are of opposing signs, as they should be. In the long run, economic development helps the third and fourth quintiles and hurts the most privileged quintile, thereby decreasing inequality. However, its impact on the two bottom quintiles is negligible. In polynomial regression, it makes little sense to report or interpret familiar standardized regression coefficients.[3] Nevertheless, one would like to compare the overall impact of economic development with that of domestic as well as international state strength. That is why the standardized coefficients of an additive function of ln ENPC and its square are provided, using the unstandardized coefficients reported in Table 2 as weights. These coefficients should be compared with the absolute values of the standardized coefficients for government revenue/GDP or trade/GNP. In the last four equations—the first two do not deserve interpretation for lack of significance—economic development always has a stronger impact than either of the state strength indicators. As far as the equations accounting for the third, fourth and fifth quintiles are concerned, the superior explanatory power of economic development over either of the state strength variables is as clear-cut as a critic of Rubinson's (1976) approach might hope for.

To summarize the results of the above reanalysis: First, Rubinson's claims concerning the beneficial impact of state control over the economic activities of its citizens are unwarranted and should be rejected, or at least no longer supported by reference to Rubinson's (1976) paper. Unfortunately, even authors (Bornschier and Ballmer-Cao, 1979:501) who avoid misspecification of the relationship between economic development and income inequality in their own work, approvingly quote Rubinson (1976) and thereby create the impression that misspecification does not matter, as if there were a cumulative body of literature supportive of some kind of dependency approach to income inequality.[4] Second, Rubinson's claims concerning the inegalitarian impact of dependence on external markets might deserve further testing because of only weak evidence in the expected direction, but the degree of support has been much exaggerated in Rubinson's paper. Third, while no cross-sectional regression analysis can ever prove that economic development leads to a more equal distribution of income in the long run—unfortunately, after a period of worsening of the income distribution—this analysis, in marked contrast to Rubinson's (1976:656), at least does not contradict "the widely held view that increasing economic . . . development will necessarily lead toward an equalization of incomes within states."[5]

For reasons of space, my discussion of the work of Rubinson and Quinlan (1977) or Stack (1978) must be extremely short. While they disagree with each other on a number of important points, they do agree on some association between democracy and income equality that is neither spurious nor produced by economic development. As neither Rubinson and Quinlan (1977) nor Stack (1978) properly controlled for economic development, since both studies misspecified the relationship between economic development and income inequality, their results cannot be admitted as positive evidence. A replication of these studies properly controlling for economic development, however, does not result in a major revision of their reported findings, as far as the association of democracy and income equality is concerned.

---

[3] Familiar standardized regression coefficients for ln ENPC and its square in Table 2 would run as high as 3.52. Such results are due to extreme multicollinearity (0.99) between ln ENPC and its square. However, none of the coefficients or significance levels concerning state strength nor variance explained is affected thereby. To demonstrate this, one may subtract the mean of ln ENPC from all such values and enter this new variable as well as its square in the polynomial regression. This brings multicollinearity down from +0.99 to −0.21 without affecting variance explained, as well as unstandardized or standardized regression coefficients of state strength variables. Therefore, the major conclusions of this paper are unaffected by this problem.

[4] One more such paper suffering from specification error and published in the *ASR* is Chase-Dunn (1975).

[5] In this context, "necessarily" is quite an unfortunate choice of words.

COMMENTS

DARWIN, SOCIOBIOLOGY AND SOCIOLOGY*

(COMMENT ON QUADAGNO, *ASR*, FEBRUARY, 1979)

Quadagno's thoughtful and scholarly article (1979:100–9) on paradigms in evolutionary theory reaches the conclusion that sociobiology is not applicable to human social behavior because of internal logical flaws, methodological inadequacies, and the complexity of human behavior. But Quadagno's understanding of sociobiology is fundamentally flawed and her conclusions should not be accepted. I will not discuss every problem I find in Quadagno's paper, but will confine myself to four issues: the relationship between sociobiology and Darwin's theory of evolution by natural selection, the charge that sociobiology is tautologically useless, the internal consistency of sociobiology with respect to the models for the evolution of altruism, and the applicability of sociobiology to humans.

Darwin and Sociobiology

First, Quadagno is, in fairness, to be complimented for her treatment of the relationship of Darwin's theory to earlier theories of evolutionary change. In particular, she sees that Darwin rejected the ideas of progress and direction present in other evolutionary formulations. What is startling, and to me incredible, is the charge that sociobiology has reintroduced these ideas. This reintroduction, Quadagno (1979:103) alleges, takes place with the introduction of the notion of reproductive maximization. This is said to change natural selection from "a minimum principle, becoming positive when any relative advantage in breeding is produced, to a maximizing one." This is not true.

The basic view of natural selection held by sociobiologists is simply a restatement of Darwin with the addition of Mendelian genetics. The thesis is simple and obvious: Genes produce organisms, in the sense that they carry the blueprints (from which the physical organisms will be constructed) and more or less explicit instructions—software, if you will—about how the organism is to act during its lifetime. Different sets of genes produce different models of the organism and, of course, each individual has particular life experiences that further influence its behavior. Some individuals act in such a way that they leave behind them, in succeeding generations, more copies of the genes that produced them than are left behind by other individuals. These genes become proportionally more common in the population, and evolutionary change takes place. This is simply Darwin's minimal principal, restated in genetic terms.

In restating Darwin's theory of evolution in terms of natural selection at the gene level, sociobiologists have argued that natural selection favors organisms that leave behind more genes than others, and that this selection results in organisms that act as if their goal were to maximize their reproductive success under the given ecological constraints (Greene et al., 1979). Quadagno has *understood* sociobiologists to be saying that natural selection is purposeful, when what they *are* saying is that natural selection produces organisms whose behavior is purposeful.

It is not natural selection that is operating to maximize inclusive fitness, it is the individuals produced by natural selection (see, especially, Dawkins, 1976). To suggest that natural selection operated purposefully would be teleological, involving a cause in the future. This is not being suggested; natural selection remains a passive, minimal process, ridden with blindness and chance. Not so the organisms that result from natural selection; they behave purposefully. No teleology is involved in suggesting that organisms behave purposefully. Mechanistic explanations of purposive behavior are possible, and the world about us is rife with apparently purposive automata ranging from thermostats to guided missiles (Rosenblueth et al., 1943).

Tautology

Quadagno (1979:104) charges that sociobiology contains an inevitable circularity, and is therefore useless as a theory.

> Fit behaviors are selected for, while nonfit behaviors are selected against. Thus, if a given behavior is exhibited by a species and typical of that species, it must be fit. There is an obvious tautology to this argument that was not present in the original concept of fitness.

---

Occasionally somebody will slip into this tautology. But even tautological statements can sometimes be useful—as Russell (1971:309) pointed out, all of mathematics can be viewed as a tautology. More importantly, when the definitions are coupled with observations of particular situations it becomes possible to make specific predictions. Here is Wilson's (1975:67) discussion of the problem, taken from the page cited by Quadagno:

> Discussion of evolution by natural selection often seems initially circular: the fitter genotypes are those that leave more descendants . . . the genotypes that leave more descendants have greater Darwinian fitness.

But the circularity is broken when we observe that changes in gene frequency are determined by the relationship of the organism to its environment:

> Under natural conditions . . . variations in competence can stem from many causes: different abilities in direct competition with other genotypes; differential survival under the onslaught of parasites, predators, and changes in the physical environment; variable ability to penetrate new habitats; and so forth. (Wilson, 1975:67)

Fitness and adaptation are not simply defined after the fact—one looks at the material relationship of the organism to its surrounding environment.

Internal Consistency and Altruism

As Quadagno notes, the problem of apparently altruistic behavior is critical to sociobiological theory. How could a gene or genes spread if they cause the bearer, the organism they made, to make some sacrifice for the benefit of another organism? Would not the genes of the *recipient* be the ones more likely to be seen in the next generation? If it is true that behavior is subject to natural selection then there must be hidden payoffs for apparent altruism. The first problem is to develop models of what these hidden payoffs might be. The second problem is to use these models to make further predictions. The third problem is to test these predictions.

Two models that point out possible hidden payoffs for apparent altruism have been developed. The *kin selection* model points out that genes for apparent altruism can become more common if the altruism is extended to individuals whose probability of carrying these genes exceeds the relative cost to the altruist of extending the altruism, and the *reciprocal altruism* model shows that genes for apparent altruism can spread if the apparently altruistic act is likely to be repaid at a later date. Quadagno's treatment of the two models would be amusing if the issues were not so serious. She claims "the two theories combined provide a perfect example of the Fallacy of Affirming the Consequent" (p. 106) because "There are almost no acts of altruism that cannot be explained as adaptive" (p. 107); dismisses the theories as "contradictory," anyway; misquotes Wilson on the evidence for the existence of reciprocal altruism in nonhumans; and finishes with a methodological disquisition that warrants separate discussion.

Let us start with the charge, originally presented by the politically motivated Sociobiology Study Group of Science of the People and then echoed by Sahlins (1977), that the theories can explain anything. It is a matter of common experience that apparent altruism is sometimes shown toward both kin and nonkin. In the absence of the reciprocal altruism model, the critics of sociobiology could (and I suspect would) point to the occurrence of altruism directed toward nonkin and say, "See, that flies in the face of your theory." Given that sociobiologists have a plausible hypothesis to explain how there *might* be hidden payoffs in apparent altrusim toward nonkin, they say, "See, sociobiology can be used to explain anything." One does not test a theory by setting for it hypothetical challenges and then condemning the theory whether or not it is able to produce a plausible explanation of how the event *might* have taken place. One tests a theory, as indicated earlier, by deducing implications and then collecting relevant data under controlled conditions.

Testable predictions follow easily from the two models. For instance:

1. Other things being equal, more apparent altruism will be shown toward kin, genetically defined, than toward nonkin.
2. Other things being equal, especially *degree* of kinship, the more likely an individual is to reciprocate, then the more likely others are to extend apparent altruism to him/her.
3. Other things being equal, the more valuable a person's help is likely to be if it is extended, the more likely others are to extend apparent altruism toward them.

Again, the point here is that testable predictions *do* follow from the models.

The charge of internal contradiction would be devastating if it were true. But the models for the evolution of apparent altruism are not contradictory. They are complementary. I base this defense not on elaborate logical analysis, but simply on the definitions of the words. *Webster's Seventh Collegiate Dictionary,* the one I happen to have on my desk, contains these definitions: "Contradictory . . . a proposition so related to another that if either is true or false the other is false or true"; and "Complementary . . . serving to fill out or complete . . . mutually supplying each other's lack." The kin selection and reciprocal altruism models are clearly complementary, not contradictory.

Finally, Quadagno (p. 107) cites Wilson as her authority for the assertion that "there are no animal examples of reciprocal altruism." This is an egregious misstatement. On the cited page Wilson (1975:120) does say that animal behavior is "almost devoid" of reciprocal altruism, but Wilson speaks from the perspective of an entomologist. In the same paragraph he gives examples of reciprocity in *six* different *Mammalian genera.*[1] Quadagno uses her misquote of Wilson as a basis for arguing that human reciprocal altruism is entirely social. Even had she not been misquoting Wilson, her argument assumes that behavior can be assigned to genetic *or* social causes, and would not be entertained by a sociobiologist.

The "Method" of Sociobiology

Following her misrepresentation of Wilson, Quadagno (p. 107) writes:

> Since the examples of reciprocal altruism consistent with genetic theory only come from human behavior, it seems more logical to suppose that in actuality, there is no genetic basis at all; it is entirely social. Further, if it is true as Wilson notes that there are no animal examples of reciprocal altruism, then how can any of the methods of sociobiology be applied? The only possible way to test the genetic basis of the behavior would be to trace it phylogenetically. However, in contrast to other less complex human social behaviors that may be traceable, reciprocal altruism is not.

There are two serious misunderstandings in this paragraph. First, sociobiologists are not interested in whether a behavior is "social" or "genetic." They assume that all behaviors have a nonnegligible genetic component and go on to ask how natural selection would act on this behavior.[2,3] Second, even if sociobiologists were willing to classify some behaviors as "genetic" and others as "social," simply pointing to the behaviors in phylogenetic relatives would not be accepted as a demonstration of a common genetic basis. There is always the possibility of an analogous adaptation.[4]

Complexity

Finally, there is the issue of complexity. Humans have speech, true, and this does add another dimension to the analysis of behavior. But, even so, lions, langurs, baboons and chimpanzees are hardly "simple" organisms. If sociobiology can make sense of otherwise puzzling features of *their* social behavior, there is no reason to suppose, a priori, that *human* social behavior will be beyond its scope.

[1] Since the publication of Wilson's synthesis there has been more systematic work on nonhuman reciprocity. Most importantly, C. Packer (1977) showed that olive baboon males form reciprocal alliances that meet the criteria of reciprocal altruism. One male will solicit help from a second, and the alliance will then drive a third male from an estrus female. The helper-male fights with the third male while the solicitor copulates with the female. The roles are reversed in later episodes.

[2] The early ethologists, Konrad Lorenz (1961) in particular, did accept the idea that some behaviors could be classified as "genetic." They also argued for natural selection on the basis of "the good of the species." Neither position is accepted within sociobiology, although the data and observations of the ethologists are historically important, as was their extended fight with the behaviorists over the importance of genetic components of behavior.

[3] Most sociologists find unsettling the assumption that any behavior can be analyzed in genetic terms. Dawkins (1976:66) writes:

> For purposes of argument it will be necessary to speculate about genes "for" doing all sorts of improbable things. If I speak, for example, of a hypothetical gene "for saving companions from drowning," and you find such a concept incredible, . . . recall that we are not talking about the gene as the sole antecedent cause of all the complex muscular contractions, sensory integrations, and even conscious decisions, which are involved in saving somebody from drowning. We are saying nothing about the question of whether learning, experience, or environmental influences enter into the development of the behaviour. All you have to concede is that it is possible for a single gene, other things being equal and lots of other essential genes and environmental factors being present, to make a body more likely to save somebody from drowning than its allele would.

[4] The classic example of analogous adaptation is that bats and birds both fly. Analogies also occur between closely related species, so independent evolution is possible. The assumption of a common genetic basis simply on the grounds of relatedness is unsafe.

REPLY TO MORGAN*

The central aspect of my original paper (Quadagno, 1979) which has aroused the ire of sociobiologists is my concern for the applicability of sociobiological theories to the study of human social behavior. In his opening paragraph, Morgan (1980) states that this is one of the four issues he intends to discuss. Unfortunately, he never does so. Rather, he reserves the final portion of his comments for a critique of what I say about the method of sociobiology. First, let me respond to his methodological concerns. Then, I will reexamine the issue of human social behavior.

Morgan (1980) raises two objections to my summary of sociobiological method, both of which he attributes to a "misunderstanding" of how sociobiologists conduct their inquiries into human social behavior. First, he states that sociobiologists are not interested in measuring the genetic component of social behavior; rather, "they assume that all behaviors have a nonnegligible genetic component and go on to ask how natural selection would act on this behavior." Second, he appears to reject phylogenetic analysis as an acceptable sociobiological approach due to the problem of recognizing analogous adaptations (even though he uses it in a footnote to exemplify reciprocal altruism in baboons). While I would agree with Morgan that there are problems with both of these approaches, he seems to forget that they are advocated by Wilson (1975) in his final chapter on humans. Thus, in discussing cultural variation, Wilson (1975:550) notes:

> Although the genes have given away most of their sovereignty, they maintain a certain amount of influence in at least the behavioral qualities that underlie variations between cultures. Moderately high heritability has been documented in introversion-extroversion measures, personal tempo, psychomotor and sports activities, neuroticism, dominance, depression, and the tendency toward certain forms of mental illness such as schizophrenia. Even a small portion of this variance invested in population differences might predispose societies toward cultural differences. At the very least, *we should try to measure this amount*. (Emphasis, mine)

The second approach advocated by Wilson (1975:551) is phylogenetic analysis. He states, "By comparing man with other primate species, it might be possible to identify basic primate traits that lie beneath the surface and help to determine the configuration of man's higher social behavior." He then goes on to describe, in detail, just how this type of analysis might satisfactorily be performed on human social behavior, discussing both the disadvantages and the possible means of overcoming them.

In disregarding two of the methods suggested by Wilson, Morgan (1980) advocates the evaluative approach, defined as the attempt "to evaluate the adaptive significance of observed behavior patterns" (Barash, 1977:54). Morgan also states that theories are tested by deducing implications and then collecting data under controlled conditions. In order to illustrate just how evidence is used to determine the adaptive significance of observed behavior patterns in humans, I will analyze an extensive example from the sociobiological literature.

A good deal of sociobiological analysis concerns strategies that maximize reproduction (Daly and Wilson, 1978:264). One of Wilson's hypotheses is that dominance confers a reproductive advantage. He cites several examples from the animal literature which demonstrate that, in animals which establish a dominance hierarchy, dominant males sire more offspring (Wilson, 1975:288). He then extends the analysis to data from a study of the Yanomama Indians of Brazil which showed that politically dominant males fathered a disproportionate number of children, quoting the following conclusion from Neel (1970):

---

I gratefully acknowledge the helpful comments of Charles Warriner and Michael Gaines.

> Our field impression is that the polygynous Indians, especially the headmen, tend to be more intelligent than the nonpolygynous. They also tend to have more surviving offspring. Polygyny in these tribes thus appears to provide an effective device for certain types of natural selection. Would that we had quantitative results to support that statement. (Quoted in Wilson, 1975:288)

In this culture, success was equated with political power (and, implicitly, intelligence) and was also associated with higher rates of reproduction. Implication? Political dominance and intelligence confer a positive adaptive advantage, being directly correlated with reproductive success—that is, with fitness.

These conclusions have been extrapolated by other sociobiologists to other measures of social success. Thus, Daly and Wilson (1978:289–90) state, "It is a common prejudice to suppose that the poor reproduce at an especially high rate but . . . several studies have shown a positive relationship between wealth and fertility." As evidence, they cite a study which demonstrated a definite correlation between number of living children and affluence. Implication? Wealth confers a positive adaptive advantage, being directly correlated with reproductive success.

The obvious difficulty with these sociobiological conclusions is that equally selective evidence could be mobilized to prove just the opposite. Thus, in Terman's study of gifted children with IQs of 135 or more, he found that they had somewhat fewer children by mid-life than the population at large (Terman and Oden, 1959). Similarly, a study of social class and family size in Peru found an inverse relationship between class and fertility—the poor had significantly more children (Stycos, 1968:148). Implication? Wealth and intelligence confer *no* adaptive advantage, being negatively related to reproductive success. Other research indicates that the very rich and the very poor have the largest families, with other income groups falling in between in terms of family size (Thomlinson, 1965:176). I am certain that a sociobiological explanation of the adaptive significance of this pattern, too, could be easily devised. Sociobiologists warn of "the danger in being too easily convinced by one's own cogent-sounding speculations, which nonetheless remain unverified" (Barash, 1977:54), but they seem unable to heed their own advice.

In specifying how to test a theory, Morgan (1980) emphasizes the phrase, "other things being equal," and stresses collecting data "under controlled conditions." What other things are equal? Where are the controlled conditions? In fact, human sociobiology is a highly speculative venture, in which selected evidence is used to prove that observed behaviors are examples of maximal reproductive strategies. For instance, Daly and Wilson (1978:290) reject the inclusion of industrialized countries for examining the relationship between fertility and social class, stating that the amount of reproductive variance in modern societies is too small. However, just a few pages later (p. 295), they cite Rainwater's survey of family design and attitudes in three American cities as an example of the persistence of pronatalism (an attitude equivalent to the desire to maximize one's reproductive success). Many more examples could easily be found. The method Morgan advocates simply is not used in the manner in which he asserts it is.

Now according to Morgan (1980), I do not understand the sociobiological view that natural selection produces organisms whose behavior is purposeful. Morgan is incorrect in his presentation of my view. In a reference to maximization, in which I quoted several sociobiologists in order to emphasize their preoccupation with this concept, all quotations referred to individual organisms (Quadagno, 1979:103). These quotations emphasized that natural selection produced organisms who were striving to maximize the number of successful offspring. Clearly, I am aware of what sociobiologists say. The conflict arises in regard to the interpretation of meaning, particularly the meaning of "purpose." Morgan engages in a familiar and peculiar bit of semantic manipulation by first declaring that "purpose" refers merely to a descriptive categorization or literary shorthand, as in the apparently purposive behavior of thermostats. If the analogy is to hold, then Morgan must accept the fact that "purposeful" behavior of organisms means only that organisms reproduce themselves the best they can (whether or not they are successful). Success cannot be used as a criterion for the anticipation of outcome (purpose) that guides the behavior of the organism. A thermostat does not anticipate outcomes. However, Morgan does not maintain the analogy, for he also uses purpose in a nonsymbolic, anticipatory sense—that is, by stating that organisms behave purposefully. The fact that Morgan vacillates between a literary and a literal interpretation elicits his second problem. How can natural selection remain a passive, minimal process when the orienting force of evolution is transferred to the organism, an organism which behaves purposefully to maximize its own inclusive fitness? The central erroneous hypothesis of sociobiology is not expunged by merely relocating purpose from nature per se to that part of nature called organism.

I also argued that sociobiologists tend to speak as if evolution produced maximal solutions which makes sociobiology irrefutable and tautological. Specifically (Quadagno, 1979:105), I stated, "... making the assumption that behaviors which presently exist represent the maximal adaptiveness of the organism makes it impossible to find behaviors which are not maximally adapted; by definition they cannot exist." The assumption of adaptiveness is central to sociobiological thought, and statements to this effect permeate sociobiological explanations. For example, Barash (1977:300) begins many paragraphs, "Assuming once again that human behavior has evolved to maximize individual fitness. . . ." If we make this assumption, then we can take any observed behavior pattern and produce a plausible explanation for its adaptive significance. Morgan's (1980) only response is to state that the circularity is broken by looking at the material relationship of the organism to its environment. How does one look at the material relationship of an organism to its environment when the "organism" is human and the "environment" is society? Further, why must we necessarily make the assumption of adaptiveness? Morgan's response is neither an argument nor an explanation. It is merely an assertion which allows him to avoid dealing with the very questionable assumptions that are built into sociobiological theories.

I have already discussed the issue of tautology in regard to reciprocal altruism in detail elsewhere (Quadagno, 1980). I see no value in repeating that argument here. In regard to Morgan's (1980) charge that I misquote Wilson in terms of the presence of reciprocal altruism in nonhumans, I would like to quote Wilson's complete statement, which is hesitant in tone, if not an outright denial:

> Human behavior abounds with reciprocal altruism consistent with genetic theory, but animal behavior seems to be almost devoid of it. Perhaps the reason is that in animals relationships are not sufficiently enduring, or memories of personal behavior reliable enough, to permit the highly personal contacts associated with the more human forms of reciprocal altruism (Wilson, 1975:120).

It is true, as Morgan (1980) asserts, that Wilson does subsequently list animal species where reciprocal altruism supposedly occurs, but it is merely a list of names. He does not document this list in any way or cite one single piece of research as confirmation.

Morgan (1980) repeats the basic tenets of evolutionary theory, including a stress on the importance of environmental influences, and then proceeds to ignore these basic elements as well as the ecological constraints upon them. Sociobiology does not proceed by testing predictions derived from theoretical models, as Morgan claims. Rather, it uses deductive logic to establish both evidence and conclusions, conclusions which are predetermined by the initial assumption of adaptiveness.

COMMENT ON WALTER R. GOVE AND MICHAEL HUGHES, "POSSIBLE CAUSES OF THE APPARENT SEX DIFFERENCES IN PHYSICAL HEALTH"

(*ASR*, FEBRUARY, 1979)*

Although males have higher mortality rates than females, health surveys often show that females have higher morbidity rates.[1] Females also have higher rates of restricted activity, doctor and dentist visits, and medicine use. Taking into account reproductive problems and health care for them, the sex differences are reduced but do not disappear. Sex differences in health are a longstanding and pervasive phenomenon; they have been reported for many years and in many countries. But, until recently, data to test hypotheses about why the differences occur were very limited.

[1] "Morbidity" means physical illness and injury. The term "health behavior" includes all curative and preventive actions, such as short-term disability (re-

Using survey data for Chicago adults, Gove and Hughes (1979) examine sex differences in several health indicators. They believe that women do have poorer physical health than men, and they state their research aim: "We will present evidence to test the hypothesis that the apparent higher rates of morbidity [for women] are due to real differences in occurrence of physical disorder" (p. 131).

Gove and Hughes (1979) present results for two health indicators: (a) general health status, rated from excellent to poor, and (b) recent restricted activity because of "not feeling well." Both indicators show poorer health for women than for men. The authors posit that (a) poor mental health and high demands to help other family members lead to poor physical health, and that (b) women are disadvantaged for both mental health and nurturant role demands. If so, these factors account for part of the original sex difference in health. Gove and Hughes choose indicators for the two concepts and then use multiple regression procedures to look at how the sex difference changes when mental health, nurturant role demands, and several demographic characteristics are controlled. An external control variable (marital status/living arrangement) is used; equations are computed separately for four groups. For both dependent variables, Gove and Hughes report that the initial sex difference (usually statistically significant) is reduced and is not significant after controlling for the three types of predictors. They conclude that the results support the hypothesis that "the sex differences in physical health largely reflect real differences in physical health, and that this difference can be primarily attributed to women confronting more nurturant role demands and generally being in poorer mental health" (p. 143).

This comment considers how well Gove and Hughes (1979) test their hypothesis. It concludes that the dependent and independent variables are poorly operationalized and that the model tested is inadequate to explain sex morbidity differentials.

THE DEPENDENT VARIABLES

Reviewing health statistics, Gove and Hughes (1979) state that "the apparent higher rates of morbidity among women are based almost exclusively on higher rates of mild transitory disorders, and the task of determining the cause(s) of the apparent higher rate of morbidity among women must focus on these types of disorders" (p. 127).[2]

Three questions arise:

1. Accuracy. Is the summary of statistics accurate?
2. Coverage. Should research focus only on indicators with higher female rates?
3. Measurement. Are the health indicators used by Gove and Hughes good measures of "mild transitory disorders?"

The first two questions concern the rationale for choosing dependent variables. The third concerns measurement of those variables.

Accuracy

Gove and Hughes (1979:126) note that females have higher rates for many indicators of acute conditions, short-term disability, and health services use. They (pp. 126–7) find one exception: "There is, however, one rate that, while very small, is inconsistent with this pattern. Males are more likely to have more serious and incapacitating chronic conditions."

Actually, quite a few indicators show poorer male health: males have higher injury rates at all ages, higher partial work disability due to health, more severe mobility problems from chronic conditions, higher rates of institutionalization for poor health until elderly ages, and longer hospital stays at all ages. Males have higher prevalence rates for many "killer" (leading causes of death) conditions, both in health interview data and medical examination data. In early childhood, poorer health for males is especially common. Boys have higher rates than girls for most health indicators, whether they refer to acute or chronic problems.

---

stricted activity), long-term disability, health services use, medicine use, and preventive health habits. The term "health" is comprehensive, including both morbidity and health behavior.

[2] In health surveys, acute conditions are defined as transitory problems, whereas chronic conditions are long-term. (Operationally, acute conditions are problems with recent onset: for example, within the past three months. See Howie and Drury, 1978:51–53.) Gove and Hughes (1979) are apparently asking that research focus on acute conditions of mild severity.

As Gove and Hughes (1979) note, females tend to have higher rates for acute conditions and curative actions taken for them. But higher female rates are not limited to "mild transitory disorders." In health surveys, females report that they have more chronic conditions than men do. They have higher prevalence rates for many chronic conditions, although few of these are leading causes of death. Women are more likely to have complete work disability and house confinement due to chronic conditions.

Gove and Hughes's (1979) statements that (a) higher female morbidity is "based almost exclusively on higher rates of mild transitory disorders," and (b) higher male morbidity appears for "one rate," simply do not match the data. There is much more variation in the direction and size of sex differentials than those statements suggest.

Coverage

Gove and Hughes (1979) imply that research on sex differences in health should focus on items with higher female rates. There is no good substantive reason to do so. Explanations should be tested for a full range of health indicators, whether they show a male or female disadvantage. This is good scientific practice, and it is the best way to obtain strong support for a theory about why men and women differ in their health and health behavior.

(The same point can be made for large and small differentials. Sex differentials are the net result of many factors acting on men and women. These factors may "compete," some acting to boost male morbidity and others to boost female morbidity. A small sex differential can be the result of large competing factors. Thus, analysis of small differentials can be just as informative theoretically as analysis of large ones.)

Measurement

Given that the authors choose to study "mild transitory disorders," how well do their indicators fit that concept? Do they measure *physical health* (morbidity) and *mild transitory* problems?

Gove and Hughes (1979:134–5) present results for two indicators: general health status and "functional impairment." The first is a respondent's subjective evaluation of his/her overall health. The second refers to recent restricted activity ("whether or not during the past two weeks the respondents did not perform various activities because they were not feeling well").

General health status is a common health indicator in surveys. Its relationship to other indicators has been studied: it is strongly correlated with more-specific measures of physical health, and also strongly correlated with measures of psychological and social health (Tessler and Mechanic, 1978; Wan and Livieratos, 1978; Ware et al., 1978a; 1978b). It is, therefore, not a *distinct* indicator of physical health. In fact, it may be a better measure of general well-being than of physical health. Moreover, people's evaluation of their general health status is certainly influenced by the presence and severity of chronic conditions as well as of acute (transitory) ones.

"Functional impairment" is also far from the mark. Recent health problems may indeed be mild and transitory, but some are severe, and many are flare-ups of chronic conditions—or persistent symptoms from them. Moreover, the indicator used by Gove and Hughes (1979) concerns a health behavior, not the presence of illness or injury. The authors did construct an indicator for "the occurrence of any illness (that is, not feeling well)" in the past two weeks (pp. 134–5). This is closer to a measure of morbidity, although it is not limited to mild transitory problems. Gove and Hughes state that analyses were performed for the "occurrence" variable and that results are similar to those for "functional impairment," but they choose to show results for the latter.[3]

Summary

In summary, Gove and Hughes (1979) analyze several health indicators and show results for two of them. The indicators do not match at all well the concept of "mild transitory disorders." General health status is correlated with other measures of mental and social health. "Functional impairment" measures health behavior, not health status. Neither item is limited to mild transitory problems. This has important implications for the results, which I will soon discuss.

THE PREDICTOR VARIABLES

Gove and Hughes (1979:132) want to see if sex morbidity differentials are due to differences in the mental health and nurturant role demands of men and women. They expect that

---

[3] A note about terminology: normally researchers use the term "impairment" to mean a defect, usually static in nature, which permanently decreases a person's ability to perform some activities (see Howie and Drury, 1978:53). Gove and Hughes's (1979) label "functional impairment" is poorly suited to the survey items covered, and it is very misleading.

"poor mental health is causally linked to poor physical health and [because women have poorer mental health] this partially explains the higher rates of morbidity among women." They also expect "that certain types of role obligations interfere with one's ability to care properly for oneself and thereby produce minor forms of disability, and that such obligations occur more frequently among women and therefore partially account for their higher rate of morbidity."

There are three critical issues about the predictors:

1. Causation. Does poor mental health induce poor physical health? How? Do high nurturant demands reduce one's physical health? How? Do causal ties run the opposite direction, so that poor physical health leads to poor mental health and also decreases home responsibilities?
2. Measurement. How well do the selected items measure mental health and nurturant role demands?[4]
3. Conceptual Fit. Is an item a distinct measure for a theoretical concept, or is it related to other concepts too?

I shall focus on the third problem.

Conceptual Fit

Gove and Hughes's (1979) conceptual scheme contains three types of predictors: "artifacts," "role correspondence," and "real illness."[5,6] To support their hypothesis that sex morbidity differentials are "real," Gove and Hughes need predictors that measure risks of physical illness. Conceptually, these are "real illness" predictors.

The measures of mental health (also called psychiatric symptoms) and nurturant role demands do not fulfill those criteria very well. In fact, they may measure predictors of competing hypotheses, which claim that sex morbidity differentials are due to differences in health perceptions and attitudes: reports of psychiatric symptoms reflect "real" mental health status and *also* a person's perception of symptoms and willingness to report them. In the conceptual scheme, perception and willingness are "artifacts." Similarly, people with high demands to care for family members may become more sensitive to their own health. They may also feel that fulfillment of family roles depends on their good health, and this may encourage preventive and curative health actions. Sensitivity is an "artifact," and propensity to care for one's own health in order to fulfill family roles is "role correspondence."

Thus, even if good measures of mental health and nurturant role demands are used, they probably represent more than "real illness" risks. It is very likely they are related to health perceptions and attitudes which are contained in the "artifacts" and "role correspondence" concepts. This is especially plausible for Gove and Hughes's (1979:133) nurturant-role-demands items. The question on illness susceptibility is a good indicator for health perceptions (Becker, 1974): "If someone else at home is sick with the bug, do you often seem to catch it?" And the last three questions concern a person's ability to adopt the sick role: "When you are *really* sick, are you almost always able to get a good rest?"; "Even when you are really sick, are there a number of chores you just have to do?"; and "When you are really sick is there someone to help take care of you?" Using these items as if they were distinct measures of "real illness" invites trouble. The next section discusses the trouble.

---

[4] For example, there are more-direct indicators of nurturant role demands. Some simple and reasonable candidates are marital status and living arrangements. Gove and Hughes might have used these as predictors rather than as control groups.

[5] Based on several articles (Mechanic, 1976; Nathanson, 1975; 1977; Verbrugge, 1976a; 1976b), Gove and Hughes (1979:127–31) identify three main explanations for sex differences in health. These are "an artifact," "the correspondence between the woman's role and the sick role," and "real differences in illness."

"Artifacts" include symptom perception, willingness to talk about symptoms, propensity to use health services, and ways physicians treat patients. Medical sociologists usually call these factors *illness behavior* (cf. Mechanic, 1962; 1978). In the "artifacts" concept, Gove and Hughes (1979) include people's willingness to discuss symptoms with interviewers. This is a reaction to the interview situation, or *health reporting behavior*. In a conceptual scheme, it is probably good to keep these reactions to a special situation distinct from everyday illness behavior.

"Role correspondence" is viewed by medical sociologists as one aspect of *illness behavior*. It refers to how a person's roles encourage or discourage symptom perception, health services use, and other curative actions.

"Real differences in illness" refers to *genetic risks* of illness and *acquired risks* of illness and injury from people's social roles, life styles, stress, and responses to stress.

Gove and Hughes's (1979) scheme is awkward compared to the articles they cite. The categories italicized above are the principal ones used by Verbrugge (1976a; 1976b; 1979; forthcoming).

[6] A note on terminology: artifacts are factors that produce undesirable variation in data. Clinical epidemiologists might view illness behavior as an artifact. But medical sociologists do not; to them, illness behavior is a key theoretical interest. The label chosen by Gove and Hughes (1979) is misleading.

THE MODEL

Gove and Hughes's (1979) model is designed to include predictors about "real illness" risks and dependent variables about "mild transitory disorders." Predictors for "artifacts" and "role correspondence" are not included. Is this a good model through which to learn about sex differences in health?

It is risky to create a model which tests only the hypotheses one believes are true but deliberately excludes hypotheses believed to be untrue. What if predictors for the included hypotheses are correlated with predictors for the excluded ones? In other words, because of poor conceptual fit or measurement error, the included variables partly reflect concepts which are supposed to be absent. The consequences can be quite pernicious: results which apparently support the included hypotheses may actually support excluded hypotheses, a fact unperceived by researchers who see their favored hypotheses faring so well.

This is an especially critical issue for Gove and Hughes's (1979) analysis. The authors do acknowledge that the dependent variables are not "pure" measures of physical health. They (pp. 134–5) note that the variables may be influenced by symptom perceptions, propensities to take curative actions, ability to adopt the sick role, and the interview situation. This, they say, will work against their hypothesis: "Real illness" predictors will not account for all of the sex differential in such variables. If the included predictors do manage to account for *most* of it, that is strong support for the hypothesis. By this reasoning, Gove and Hughes conclude that the dependent variables actually permit a very good test of the "real illness" hypothesis.

This argument depends on an important assumption: that the predictors do indeed measure illness risks closely and distinctly. If they do not, the analysis strategy leads instantly to trouble. Earlier, I stated that indicators of mental health and nurturant role demands will often reflect "artifacts" and "role correspondence." If so, the model's predictors contain multiple concepts. The dependent variables in this case contain the same ones. What do correlations between the predictors and dependent variables then mean? Not necessarily what Gove and Hughes (1979) expect.

For example, people who are willing to report psychiatric symptoms are probably also willing to report physical health problems. If women are more-willing reporters than men, a sex morbidity differential can be accounted for by the predictor. But it does not support the "real illness" hypothesis. Instead, it supports the "artifacts" hypothesis. Another example: people with high nurturant role demands have health on their minds and may be as concerned about their own health as about others'. As a result (or as a correlate), they may view their general health status less favorably than other people do, and they may take more health actions for themselves. Gove and Hughes's (1979) five items are especially prone to such relationships. In their data, women express more concerns about sleep, susceptibility, and family support when ill than men do. Thus, the items can account for a sex morbidity differential while saying nothing about real illness of the sexes. Instead, the results support the "artifacts" and "role correspondence" hypotheses.

In summary, correlations between the predictors and dependent variables may support hypotheses about "artifacts" and "role correspondence." But in the context of Gove and Hughes's (1979) model, the correlations are accepted as evidence for the "real illness" hypothesis.

PROCEDURES

Multiple Classification Analysis (MCA) uses nominal-level predictors and interval-level dependent variables. "Functional impairment" is dichotomous (Gove and Hughes, 1979:135) and, therefore, meets the criterion for dependent variables. General health status is ordinal, with four categories. Gove and Hughes do not state how it is transformed into an interval-level variable for analysis. The presentation of results in Table 3 does not resolve the question. In fact, Table 3 is exceptionally difficult to understand. It does not follow MCA conventions: normally one should be able to read the average health status of males and females, controlling for certain predictors. If the health variable is dichotomous (for example, "excellent" vs. "other"), one then reads the percentages of males and females with "excellent" health. But in Table 3 the variables are reversed. One reads the percentage of people in the four health ratings who are male. (The second column showing percentage female is extraneous.) In short, we see sex by health status instead of health status by sex. Sex appears to be the dependent variable instead of the independent one. For people familiar with MCA, it is entirely unclear how Gove and Hughes produced the results in Table 3. Even without that familiarity with MCA, it is difficult to read the table and verify Gove and Hughes's (1979:140–2) discussion.

CONCLUSION

Gove and Hughes (1979:131) begin with an intriguing question: Why do females often have higher morbidity than males? They decide to test the general hypothesis that "the apparent higher rates of morbidity are due to real differences in occurrence of physical disorder." They decide *not* to test two other general hypotheses: Higher female morbidity is due to illness behavior and health reporting behavior ("artifacts") or to ability to adopt the sick role ("role correspondence"). To test their hypothesis, Gove and Hughes include predictors for mental health status and nurturant role demands, which they believe influence physical health. For dependent variables, they focus on mild transitory disorders, which often show higher rates for females.

But the predictor items chosen are not distinct measures of "real illness" risks: the mental health items may be affected by perception and reporting factors. The nurturant-role-demands items reflect perceptions and ability to adopt the sick role. Thus the mental health items say something about "artifacts," and the other items say something about both "artifacts" and "role correspondence." These factors are also present in the dependent variables. As a result, correlations between predictors and the dependent variables may say more about the two excluded hypotheses than the included one ("real illness").

Additional problems arise: the dependent variables are not good indicators of mild transitory problems. For the predictors, there are serious issues of causality and measurement.

For numerous reasons, then, the results do not test Gove and Hughes's (1979) favored hypothesis. What they *do* say about sex differences in health is hard to determine.

Could analysis of the Chicago data be more informative? Possibly. The data set apparently has few health variables, but it may have more variables which could serve as predictors for "artifacts," "role correspondence," and "real illness." By more careful assessment and choice of predictors, Gove and Hughes (1979) might have created models that test several hypotheses at the same time and that better separate the effects of artifacts, role correspondence, and real illness. Results could be compared for the morbidity variables vs. the health behavior variables. The critical point is to broaden the model and to understand the properties of predictor and dependent variables.

In general, it is better to test all principal hypotheses for a social behavior (or at least all that one's data permit), rather than only the hypotheses one likes. Then researchers can examine correlations among predictors, compute net effects, and assess the relative support for favored and disfavored hypotheses (if "sides" have been taken for them). Data often have limitations that preclude the testing of all the principal hypotheses. Researchers should then announce this and use extra caution in interpreting results.[7]

Finally, although Gove and Hughes (1979) imply that other researchers are content to speculate about reasons for sex differences in health and do not try to test them, the truth is quite different. Until recently, empirical work was hampered because health data sets lacked enough predictors to test a variety of hypotheses. There is now active research to collect appropriate data and also to conduct secondary analyses (see Davis, 1979; Marcus and Seeman, 1979; Verbrugge, 1979). In the next decade there will be plenty of pertinent research results. It will be especially interesting to see results for a variety of dependent variables which encompass the incidence and prevalence of health problems, many types of curative health actions, and preventive health actions. Whether they show a female or male excess, or a large or small sex differential, should not be a criterion for selection. With a wide range of dependent variables, a more general theory will emerge about how women and men perceive symptoms of illness and injury and how they respond to those symptoms.

COMMENT ON GOVE AND HUGHES*

(*ASR* FEBRUARY, 1979)

There are numerous difficulties with the Gove and Hughes paper in the February, 1979, issue, but the key difficulty is that their analysis, like the earlier Gove and Tudor (1973) work on sex and mental health, creates confusion by using dependent measures that are not appropriate to the questions that are being raised and then asserts conclusions about measures (in this case, mild physical illness) that their data do not address.

It is the position of Gove and Hughes (1979) that higher rates of morbidity among women, as compared with men, result from a higher prevalence of "mild forms of physical illness," and that this results from poorer mental health and demands of a nurturant role. Given this hypothesis, one might have expected Gove and Hughes to investigate carefully sex differences in morbidity due to "mild forms of physical illness" and to seek instances in which their occurrence is independently validated to some extent. They do not do this.

Although Gove and Hughes (1979) purport to address the issue of mild physical differences, the choice of their dependent variables is inappropriate for this task. The measures used were a rating of "overall health" and an index of "whether or not during the past two weeks the respondents did not perform various activities because they were not feeling well" (p. 135). Although Gove and Hughes note that the later measure was "virtually interchangeable" with other indicators they had, all of the indicators they describe are gross indicators of response and behavior, not measures of symptoms or illness.

Gove and Hughes missed the point of the criticism made in an earlier study (Gove and Tudor, 1973) and make a similar error in the analysis of sex and physical illness. The point of the criticism is not that such entities as alcoholism or personality disorder need necessarily be defined as mental illnesses. The concept of mental illness is vague, and the definition of its constituents is arbitrary and largely determined by social definitions. The objection to Gove and Tudor's procedures is that they selectively aggregated entities into the definition of mental illness that are differentially related to sex but, in the aggregate, support the conclusion they wish to promote. The result is confusion and obfuscation, rather than improved understanding. It is fairly well established, for example, that there is no consistent sex difference in schizophrenia (Dohrenwend and Dohrenwend, 1969) but that the prevalence of depression is higher in women than in men (Weissman and Klerman, 1977). Because depression is more prevalent than schizophrenia, a combined index of the two will be correlated with sex; but noting such a correlation tells us nothing new and substitutes confusion for more refined information.

Gove and Hughes (1979) attempt to justify the illness response and behavior measures they use as proxies for physical illness. But overall health ratings are general indications of well-being, known to be correlated not only with physical illness of all types but also with psychological well-being, functional incapacity, and community participation (Ware et al., 1978; Tessler and Mechanic, 1978). In short, they are poor proxies for the concept the authors address. The fact that Gove and Hughes can demonstrate that sex differences on such indicators are reduced by controlling for psychological symptoms and other health-related reports (their scale of nurturant role demands) does not provide validation for their hypothesis that women have more mild physical illness. Perhaps women do; but the Gove and Hughes data do not really address this question. Their findings, as an examination of the literature would suggest (see the review by Ware et al., 1978), result from using a global dependent variable that measures health perceptions in their broadest sense.

Similar problems exist with the vague questions said to represent nurturant role demands (Gove and Hughes, 1979:133). It is plausible that differential role strain between men and women and between women with children and women without children could account for sex differences in illness reports. A fair examination of a role-demand hypothesis, however, would sample more widely from the possible range of role demands and life strains affecting both men and women and persons at home and those employed outside the home. It is difficult to understand why Gove and Hughes chose the items used in contrast to a more representative selection.

In presenting their argument, Gove and Hughes (1979) repeatedly misrepresent my review of hypotheses and data on sex differences in physical health (Mechanic, 1976). Rather than take space here, to correct these misattributions, I urge interested readers to review the original paper (which is also available elsewhere [Mechanic, 1978]) and to come to their own judgments. A major conclusion of that paper was that there is large variability in the responses from men and women, depending on the illness conditions or symptoms involved, and that we would learn more by focusing on these variabilities in contrast to global hypotheses that attempt to explain the data in the aggregate. Gove and Hughes would have done well to have heeded this advice.

SEX DIFFERENCES IN PHYSICAL HEALTH AND HOW MEDICAL SOCIOLOGISTS VIEW ILLNESS*

(A REPLY TO MECHANIC AND VERBRUGGE)

In an important article, "The oversocialized conception of man in modern sociology,"

Support for this paper was provided by NICD Grant No. 5-RO1-HD06911-02. We would like to thank Antonina Gove and Lisa Heinrich for the comments on an earlier draft.

Dennis Wrong (1961) describes how sociologists, by viewing the nature of men and women as almost entirely a result of socialization, have a very incomplete image of human beings. Wrong is quite aware that sociologists give lip service to the inherent psychological and biological characteristics of men and women, but argues that in their research and writing sociologists virtually ignore these aspects of human nature. To a large extent there is a similar bias in the work of some medical sociologists—including Mechanic and Verbrugge, who appear to have an oversocialized conception of illness and, in absence of any compelling contrary evidence, assume that the apparent sex differences in illness must be due to social and/or psychological processes. In reading this literature, one is struck by the extent to which actual illness, scientific diagnostic procedures, and forms of effective treatment are ignored. As Mechanic (1978:210), citing Mechanic (1968) states, "It is widely recognized that the definition of illness is arbitrary and based on social and cultural understandings." In an early paper, which presents a concept that is fundamental to his subsequent work, Mechanic (1962) discusses the "concept of illness behavior" which included factors affecting "symptom perception, the willingness to talk about symptoms, the propensity to use health services and the way physicians treat patients" (Verbrugge, 1980; fn. 5). We are aware of these processes and, in fact (Gove and Hughes, 1979:144), so asserted: "There is, of course, considerable evidence that such effects [processes] do exist." The issue is whether men and women have personalities which produce fundamentally different amounts and types of illness behavior such that the apparent higher morbidity rates among women are properly viewed as an artifact (that is, as a consequence of their different forms of illness behavior).

BACKGROUND

A premise that appears to be fundamental to the work of Verbrugge and Mechanic is that women are much more likely to manifest illness behavior and that, for this reason, they appear to have higher overall rates of morbidity due to physical illness. For example, Verbrugge (1976:399) states, "We suspect that males are physically sicker from both acute and chronic conditions, but that social and psychological factors enhance female reports to such an extent that a female excess appears overall." Similarly Mechanic (1978) notes that women have higher rates of utilization of medical facilities and also that women "report many more subjective symptoms than men, particularly those symptoms that may be indicative of either physical or psychological distress." However (p. 213), he concludes "that it is difficult to support the argument that women have more illness than men." Dohrenwend and Dohrenwend (1977:192) state, "Treated rates can be expected to give a picture of excess pathology among women if only because women are more likely to avail themselves of help for personal problems, from professionals in general and from medical and psychiatric professionals in particular." They go on to indicate that the higher rates of women in community surveys of mental health are also a consequence of women being more willing to engage in illness behavior than men. As noted in our paper (Gove and Hughes, 1979), there are a number of other scholars who present similar arguments, and it is our perception that, through process of mutual citation, it is made to appear that this characteristic of women is firmly established. However, there is no clear empirical evidence that this is the case. We would note that we take this statement to be a very serious charge, but neither Mechanic nor Verbrugge comments on it. For persons focusing on illness behavior, the two most commonly cited studies are those by Phillips and Segal (1969) and Mechanic (1964). Phillips and Segal (1969) show that women reported more symptoms of distress than men and argued that this was a consequence of it being culturally more appropriate for women to admit such symptoms. However, they presented no evidence for this assertion, and three subsequent studies (Gove and Geerken, 1977; Gove et al., 1976; Clancy and Gove, 1974), using the techniques subsequently developed by Phillips (e.g., Phillips and Clancy, 1970; 1972), showed that response bias, that is, illness behavior, is not a reason why women admit to more symptoms. Mechanic (1964) looked at boys and girls on the 4th and 8th grades and found that boys, particularly in the 8th grade, were less likely to say they were "afraid to get hurt," and more likely "to ignore pain" and "not tell others that they did not feel well." These data are suggestive, but, in interpreting them, other factors should be taken into consideration. First, boys at those ages "have higher rates than girls for most health indicators" (Verbrugge, 1980). Second, a 16-year follow-up of these subjects by Mechanic (1979) found that males and females were equally sensitive to—and willing to report—subjective symptoms of distress. This longitudinal study by Mechanic, in our view, raises very serious questions regarding his own position, which holds that there are marked sex differences in this type of illness behavior. Furthermore, in an analysis of the 1975 National Ambulatory Medical Care Survey, Verbrugge (1978:1) finds that (a) "there is little evidence that men and women differ in their perception, interpretation, and description of physical symptoms" and (b) "the evidence for sex bias in physicians' diagnosis is scant."

HYPOTHESIS

As noted by Verbrugge, we (Gove and Hughes, 1979) were concerned with three possible explanations of the apparent higher rates of morbidity among women. First, it was our substantive hypothesis that the rates of higher morbidity among women are real and can be attributed to: (a) the role obligations of many women and (b) the tendency for women to be in poorer mental health. If we were correct, then, when we controlled for mental health and women's nurturant role obligations, the differences between the sexes would disappear. If we were not correct—and the differences were due to illness behavior or the greater ability of women to assume the sick role—then the health differences between men and women would have remained the same, even after controls. This procedure would not have been appropriate if either: (1) our mental health scale could be shown to be subject to reporting bias by sex; or (2) our measure of role obligations actually measured the extent to which persons were free to assume the sick role (and persons with few obligations were more likely to report poor health and functional impairment). As will be indicated here, there is no evidence for either of these potential problems.

Our null hypothesis, of course, is that controlling for role obligations and mental health would have no effect. The alternative two hypotheses revolve around illness behavior. They suggest that women tend to be in situations where they can readily adopt the sick role and/or that women were more willing to describe their physical ailments to others. If either of these hypotheses were true, then controlling for mental health and role obligations would not decrease the apparent poorer physical health of women (because it would, apparently, have been due to illness behavior). Thus, Verbrugge and Mechanic's corresponding *null* hypotheses are that, with our controls, the apparent differences between the sexes would essentially disappear. We thus had a design which would indicate whether the sex differences were real or a consequence of illness behavior and, contrary to what Verbrugge says, our analysis does provide a test of her hypothesis.

MEASURES

We (Gove and Hughes, 1979) had two dependent measures: respondents' evaluations of his or her physical health—that is, (1) their responses to the question, Was his or her physical health excellent, good, fair or poor? and (2) the respondents' functional "impairments" as indicated by the respondents' saying that during the previous two weeks they had not performed activities they *normally* did because they were not feeling well. Both Mechanic and Verbrugge are highly critical of these two measures. Ironically, Tessler and Mechanic (1978) provide perhaps the best reason for using questions of this nature in survey data. They (with supporting citations) indicate (1978:254–5) that respondents, as they do not have a medical perspective, do not deal with specific symptoms of a disease but, instead, "view their health status in a more global fashion . . . [reacting] . . . to their overall sense of well-being and the extent to which the symptoms they experience disrupt their ability to function or interfere in some fashion with their daily activities." Elsewhere, Mechanic (1978:210) indicates that "self reported medical histories are highly suspect," due to differential reporting by sex; that there are "serious problems with using reported symptoms"; and that statistics on treatment are highly reactive to sex differences in illness behavior. In short, if Mechanic is correct, respondents are better at evaluating their overall health and functional status than they are at dealing with specific aspects of various illness.

Mechanic (1980) and Verbrugge (1980) are also critical of our measures of physical health because they are correlated with a respondent's affective state. The grounds for such criticisms puzzles us. In terms of overall health and a large number of specific diseases, it is well established that one's affective state has a substantial effect on one's physical health. Our (1979) paper presents 12 citations bearing on this fact; there are numerous others. Let us here cite one; it has been repeatedly demonstrated that in placebo therapy the body produces endorphins which are chemicals with a similar structure to that of the opiate-derived painkillers and they can be very effective (e.g., see Levine et al., 1978). Given present knowledge, if our global measures of physical health were not related to a person's affective state, that would be, ipso facto, evidence that our measures are virtually worthless. We would emphasize that the fact that the physical and mental health measures are correlated does not invalidate our study, for not only should they be related but they must also account for the sex differences in physical health.[1] Furthermore, Verbrugge appears to feel that we should not have looked at functional impairment[2] and both Mechanic and Verbrugge indicate that questions dealing with the respondents' evaluations of their overall health are inappropriate because these measures are related to illness behavior. As was indicated in our paper, from our point of view this is one of the positive attributes of those measures because they weighted the analysis against our substantive premise and in favor of our null hypothesis.

With regard to our intervening variables, we can be brief. The psychiatric symptom scale is presented in the paper, and we would simply reemphasize that it contains no psychophysiological items and there is no response bias by sex (Gove and Geerken, 1977). For ease in reading the remainder of the paper, we list the nurturant role variables: (1) Do you think you get enough sleep? (2) If someone else at home is sick with a bug, do you often seem to catch it? (3) When you are *really* sick, are you almost always able to get a good rest? (4) Even if you are *really* sick, are there a number of chores that you just have to do? and (5) When you are *really* sick, is there someone to help take care of you?

MECHANIC, SPECIFIC COMMENT

(1) We, as would Mechanic, urge you to read his paper (Mechanic, 1978). It is true that we did not focus on his major point, which appears to be that you need a specific theory for every disease (Verbrugge, in *her* comment on our article, seems to concur). Instead, we focused on a much more general question—namely, Do women, in comparison to men, have a strong general tendency to engage in illness behavior? Obviously, the importance of this tendency will vary, by disease; but the answer to this general question is necessary if one is to take Mechanic's position. Mechanic should also pay attention to studies that do appear to heed his advice in that they use the type of data and analysis he indicates are appropriate. In particular, Wolinsky (1978) has conducted the type of study that Mechanic (1978:211) specifically calls for. Wolinsky (1978:394) finds that "most of the explained variants are the results of illness—morbidity characteristics. This casts doubt on the importance of predisposing and enabling characteristics in explaining health care utilization." He also finds that the "indirect effects of predisposing and enabling characteristics are negligible." We would also note that, after controlling for indices of actual physical health, in all the analyses not only was the relationship with sex statistically insignificant but also, in addition, in 11 out of 24 analyses, *men* had higher rates of utilization.

(2) If Mechanic had read the article by Gove (1978) which appeared in the same issue as Mechanic's (1978), he would have seen an update on the community studies presented initially in Gove and Tudor (1973) and realized that his comment on schizophrenia serves as a smoke screen (intended or not). Only 2 (Hagnell, 1966:99–103 and Primrose, 1962:18–24) of 34 studies presented data on schizophrenia, and their rates are so low (the largest is .4%) as to have no effect on the general conclusion, because the rates in these community surveys typically range between 20% and 30% with the differences between the sexes being substantial. It is true that in those two studies (both conducted in atypical communities) there were more male than female schizophrenics, but even with combining the two studies there are too few cases to draw any conclusion (in combination, there were six male and two female

---

[1] For example, as is shown (Gove and Hughes, 1979:139) in Table 2, psychiatric symptoms uniquely account for over 50% of the variance in the functional impairment of those who live alone but, as is shown (p. 142) in Table 4, psychiatric symptoms have no effect on the sex difference in functional impairment (because these men and women are virtually identical in their mental health). We would note that the study by Wan and Livieratos (1978) and the Rand studies (e.g., Ware et al., 1978) of the General Well-Being Scale appear to be misinterpreted by Verbrugge and Mechanic. The General Well-Being Scale was designed by Harold Dupuy to measure the respondent's *psychological well-being* [personal communication, emphasis mine] and these studies demonstrate that this is what they, in fact, do measure, with the scale's relationship to physical health being modest. Verbrugge and Mechanic also appear to be unaware of the fact that Gove et al. (1976) show that, with an earlier version of the General Well-Being Scale, controlling for three forms of response bias (that is, "illness behavior") has no effect on the rates of men and women.

[2] Verbrugge (1980) is highly critical of our use of the term "impairment" because she feels it should indicate a permanent decrease in a person's ability to perform. We would simply note that our use is consistent with the *Webster's Unabridged Dictionary* and with how the term is used in psychiatry.

schizophrenics). Furthermore, in the United States, in 1967, women had a higher first-admission hospitalization rate for schizophrenia (sex ratio = 1.16) and were also more likely to be treated for schizophrenia in outpatient psychiatric clinics (sex ratio = 1.10) (Gove and Tudor, 1971).

VERBRUGGE, SPECIFIC COMMENTS

(1) Accuracy. Verbrugge (1980) translates our study into her framework and then criticizes us on the basis of her mistranslated formulation. In our view, high injury rates, partial work disability, mobility problems, early institutionalization for poor health, and longer hospitalization all fit under the single category of "serious and incapacitating conditions." We quote Verbrugge's listing of mild chronic conditions where women have higher rates (p. 127). We also both quote parts and summarize other parts of her discussion of chronicity, causes of death, and the occurrence of presumed sex reversals (that is, she misrepresents our presentation).

(2) Coverage. We (Gove and Hughes, 1979) wrote one paper that seriously looked at the possibility that the apparent excess female morbidity rate may be higher. It was the first paper to do so but used a data set not collected specifically for that purpose and we would welcome replications.

(3) The term "mild transitory disorders." Verbrugge demonstrated that males had higher mortality rates (except from diabetes) with those illnesses where there is a high mortality rate. As Verbrugge has also noted, acute conditions are more common than chronic. In short, if women do have higher actual rates of morbidity, it has to be primarily (but not solely) among disorders which are mild and transitory.

(4) Predictors. Verbrugge (in her 1980: fn. 4), suggests that we look at marital status and living arrangements as predictors rather than as control groups. First, we have no control groups in the formal sense of the term. In categorizing by marital status and living arrangement we have men and women in comparable situations. Thus, for the married, we are able to show that both the nurturant role obligations of the wife/mother and her poor mental health are related to her poorer physical health. In contrast, when we look at persons who live alone, we see that the poorer physical health among women can be attributed to demographic variables on the general health question, whereas mental health and role obligations have no effect on sex differences in physical health.

(5) Causation. Verbrugge (1980) suggests that poor physical health and poor mental health lead to a decrease in home responsibilities. This is virtually incomprehensible as a critique of our study because, in the data we present, poor physical health and poor mental health are associated with a very *high* level of obligations in the home. Not having obligations (that is, having a role compatible with the opportunity to be ill) is related to reporting *less* ill health, *less* functional impairment, and *fewer* psychiatric symptoms. In short, the relationship suggested by Verbrugge runs directly counter to the actual direction.

(6) Conceptual fit. (a) Refer, please, to Verbrugge (1980: fn. 6): to medical sociologists, illness behavior and health reporting behavior are properly viewed as processes to be studied. However, we are concerned with the roles and mental health of men and women as possible determinants of sex differences in physical illness. In the (Gove and Hughes, 1979) present study, a characteristic which systematically distorts the actual relationship between gender and physical illness means that the relationship we are looking at is not real but an artifact of an exogenous variable. Thus, in the present study, the term "artifact" is appropriate.

(b) Now, as to role obligations and role correspondence: role correspondence deals with those factors which sensitize one to health issues and encourage one to take good care of oneself. Our role variables involve social obligations which prevent one from taking care of oneself. This is especially true of the last three items which are our most powerful role variables.

TABLE 3: MULTIPLE CLASSIFICATION ANALYSIS AND AN APOLOGY

Verbrugge notes that our (Gove and Hughes, 1979) Table 3 does not follow MCA conventions and finds it very difficult to read. She is correct that the style of presentation is unusual but, if one is familiar with MCA, it is very easy to read and our style of presentation is more informative than the normal presentation with a multicategory dependent variable, where the only unadjusted and adjusted means are presented in combination with the Eta's and Beta's. Neither of these measures allows one to look at the presence or absence of monotonicity or to decide whether the variance observed with adjustment is due to a marked shift in one category or a modest general shift across a range of categories. MCA always has the same denominator, regardless of whether one is dealing with Eta's or Beta's. In fact, the only way a Beta differs from an Eta is that the value of the dependent variable has been adjusted for the effects of all control variables—with the specification that the marginal values remain the same. In normal regression, it is often difficult to compare the strength of variable because of the issue of multicollinearity. In partial correlations, the variation that is collinear is dropped from the analysis and, thus, it is difficult to know if a partial correlation is accounting for much variance or not. With Beta's (or, for that matter, b's), collinear variance is split among the different variables with the division of collinear variance being determined entirely by the variance uniquely explained by each variable. Thus, with two very highly intercorrelated variables, if one of the variables has virtually no unique variance, and another a slight amount, the latter variable will get virtually all collinear variance and have a large b and Beta—while the other variable may have a b and Beta that barely differ from zero. With the Eta's and (MCA) Beta's there is no such problem. Looking at an Eta^2 and a set of Beta^2's (as was shown in Tables 3 and 4), one can first state in precise terms the percentage of variance uniquely explained by an independent variable and, then, compare this with the percentage of variance that is uniquely explained after controls. Alternatively, one can look at the Beta^2 associated with a set of independent variables and tell precisely what percentage of variance is explained by each predictor after the effects of all the others have been controlled for (adjusted).

Verbrugge (1980) is correct that, in order to present the percentages, we reversed the independent and dependent variables. She expresses difficulty in reading Table 3 (modified), but this is probably only because the style of presentation is unusual. For example, take the upper part of the left column where one has a simple 2 × 4 table which shows how married men and women are distributed in terms of each category of health. The next-down 2 × 4 table shows exactly the same relationship after adjusting for the effects of the demographic variables. Down one more step, one finds what those relationships are after one has adjusted for the demographic and role variables. With each step, if comparing the Eta^2 and the Beta^2's one can tell exactly how much effect, in terms of percentage variance explained, is associated with each new set of controls. As an example of information gained in this style of presentation, look at the bottom of the last two columns. The two relationships that started out monotonic are no longer monotonic, but there is no way we could tell this from the means of the health variables or from the Eta's or Beta's, as no pattern of relationship is assumed with these measures. To get the correct Eta^2 and Beta^2 for each of these analyses, all one has to do is rerun the analysis with health as the dependent variable and sex as the independent variable. However, as Table 3 has the numbers of both men and women for each health category, one could, by hand, calculate the Eta's and Beta's for both sex and health for each 2 × 4 combination.

Now comes the apology. Table 3, which—as revised—is presented here, has the correct Eta^2's and Beta^2's and mean health scores. The original Table 3 had the Eta^2's and Beta^2's, with sex as the independent variable. In creating this original table it was necessary to have two identical sets of runs, one with sex as the dependent variable and one with health as the dependent variable (see preceding paragraph). In our paper (Gove and Hughes, 1979) we inadvertently reported the Eta's and Beta's from the wrong run. Table 2, we would note, correctly had health as the dependent variable. A comparison of the original Table 3 with the present Table 3 will show no substantive differences for the married, those living alone, and those formerly married living with others. In the case of the never married living with others the final Beta^2 is now smaller, while the relationship is now just barely statistically significant (this is due to the fewer degrees of freedom in the new table and the more predictor categories in the original table). Because of the relatively large Beta^2 we had treated this as an ambiguous category open to a variety of interpretations and as one that should not be taken as supporting our hypothesis. Thus, there was nothing in our discussion or conclusion that was affected by this error.

MODELS

The models being tested are discussed (Gove and Hughes, 1979) in the first section, and a number of the problems are dealt with there. From reading the paper, Verbrugge somehow concludes the data fit the "artifacts" and "role correspondence hypothesis." She concludes (Verbrugge, 1980) that it fits the artifact hypothesis because "people who are willing to report psychiatric symptoms are probably also willing to report health problems." If she had carefully read the paper she would have realized that Gove and Geerken (1977) have shown that, with the psychiatric symptom scale used, there is *no* bias in the scores of men and women (that is, there is no difference in illness behavior). This lack of bias has been replicated twice using different scales (Gove et al., 1976; Clancy and Gove, 1974). Furthermore, if women have a general tendency to report psychiatric symptoms and/or poor

* This is a revised version of our (Gove and Hughes, 1979:140) original Table 3.

physical health, it should be fairly consistent in different living arrangements or different marital statuses. But in the present study, men and women who live alone show no such effect. Furthermore, Brocki (1979) has shown, with the same psychiatric symptom scale, that never married and widowed men articulate more symptoms than do their female counterparts. (Also see Gove, 1972; 1978; 1979).

As indicated above, the role variables reflect an *inability* to adopt a sick role. If Verbrugge had looked at Gove et al. (1979), which appeared in the same issue (as Gove and Hughes, 1979) of *ASR*, she would have found that the role items were related to household crowding, particularly to an overload of social demands.

In summary, the role variables reflect obligations to respond to the needs and demands of others, regardless of one's physical condition. It may be true that this experience sensitizes one to the need for rest and general health care, but the point is that it prevents one from taking good care of oneself.

CONCLUSION

Having systematically criticized the general orientation and specific comments of Mechanic (1980) and Verbrugge (1980) it is clear that we can find nothing in them that in any way affects our (Gove and Hughes, 1979) conclusion. We hope their comments and our rejoinder will clarify for others the issues involved. No single study provides a definitive answer, particularly when it is using a body of data gathered for another purpose, and we hope others will expand upon our measures of nurturant role obligations and attempt a replication. At the end of her comment Verbrugge notes that there are now three studies in progress that will help resolve the questions addressed in our paper and in her comment. We would only note that these studies were not in progress when our paper was written and that one of these studies, namely the one by Verbrugge, has no measures to test the hypothesis we proposed in our study even though she had a copy of that paper long before her study was initiated.

IDEOLOGY, SPECIFICITY, AND THE CODING OF LEGAL DOCUMENTS: WHAT DO MEASURES OF CONSTITUTIONAL CONTENT MEASURE?*

(COMMENT ON BOLI-BENNETT AND MEYER, *ASR*. DECEMBER, 1978)

In "Ideology of Childhood and the State," Boli-Bennett and Meyer (1978:797) attempt to "trace the emergence of differentiated and state-managed childhood at the institutional level over the last century," by drawing on a kind of evidence seldom used by sociologists: the content of national constitutions, viewed as "fundamental rules . . ." that ". . . embody very general ideological definitions of the nature of persons and society." They conclude that the emergence of a state-managed childhood ideology is highly correlated with increasing state authority and is best accounted for as a diffusion phenomenon, moving from core countries to peripheral ones (p. 810).

We applaud Boli-Bennett and Meyer's attempt to answer important questions about social change by deriving quantitative indicators from the content analysis of legal documents. We must argue, unfortunately, that the validity of their indicators is suspect, because they failed to satisfactorily resolve major problems in deciding which legal documents to code, in developing their coding rules, and in interpreting their results. The content analysis-based indicators may describe national ideologies about childhood and state authority in the way in which Boli-Bennett and Meyer claim that they do. But they probably do not. Even though Boli-Bennett and Meyer's hypotheses may prove correct (and some of those on the diffusion of legal reforms are consistent with the findings of others—for example, Collier and Messick, 1975), the data presented do not necessarily provide much evidence in their favor.

Selecting documents to code. Boli-Bennett and Meyer's (1978:798) basic hypothesis concerns "the institutional rules defining childhood . . . ." In order to analyze institutional rules, they examine the content of constitutions. Their dependent variable, the "childhood index," is a measure of the "elaboration of constitutional rules defining the nation-state as responsible for . . . children" (p. 810). In addition, two independent variables viewed as measures of general state authority—indices of state authority and of citizen rights—are also measures of the content of constitutions.

But many important institutional rules are contained in legislation, administrative regulations, and court decisions, as well as in constitutions. Boli-Bennett and Meyer (1978:800) state, for example, "Constitutions do not fully capture the extent of state involvement in childhood . . . much state involvement in childhood occurs through legislation."

Boli-Bennett and Meyer's (1978:800) major reason for excluding legislation (and other forms of state rule-making) from their analysis is apparently their belief that ". . . legislation reflects many factors besides the ideological process discussed here." They appear to be assuming—their discussion is only a footnote—that constitutions are "purer" manifestations of ideology than ordinary legislation is. They provide no evidence for this assumption that all states consistently regard constitutions as the appropriate document in which to specify their commitment to the status of childhood.

The assumption—and consequently the validity of their measures—can readily be ques-

We would like to thank Richard Wilson for helpful suggestions.

tioned. States may vary in their tendencies to institutionalize rules affecting childhood in constitutions. For example, Boli-Bennett and Meyer (1978:801) point out that the United States Constitution "contains no provisions distinguishing children as a separate category of persons with unique rights or obligations, or subject to particular state action." This lack does not reflect the American ideology of childhood in any meaningful sense, however, because ideological commitments are typically made in American state constitutions and legislation (Ogburn, 1912; Ratner, forthcoming). Israel has no constitution at all, because of intense disagreements over what should be regulated through inclusion in a constitution rather than in ordinary legislation.

In addition, nations may change over time in their tendencies to institutionalize, in constitutions rather than elsewhere, the rules affecting childhood. Lowi (1971) has provided evidence that the boundaries between different forms of state rule-making can change over time, showing that federal authority in the United States is increasingly expressed in administrative regulations rather than in legislation.

Thus, we believe that constitutions, like ordinary legislation, will reflect many factors, including politicians' ideas about what should be in an ordinary law, in administrative regulations, or in court decisions, rather than in a constitution. By examining only constitutions and ignoring other legal documents, Boli-Bennett and Meyer have developed a childhood index which measures rules affecting childhood, and cross-national differences in the inclination to put rules into constitutions, and over-time differences in the same inclination—each to some unknown degree. We cannot, therefore, know the extent to which Boli-Bennett and Meyer are measuring ideologies of childhood rather than patterns of constitution-writing.

In order to construct more valid indices, we suggest that, for each country studied, the legal documents (constitution, legislation, etc.) which contain a definition of childhood and "references to state action in relation to children" (Boli-Bennett and Meyer, 1978:800) be identified. Coding would then be carried out on all types of legal documents containing rules for state action. This alternative procedure would ensure that the focus would be on the substantive problem. (Moreover, it would provide an additional piece of information: by coding the type of legal document, one could also determine which legal documents encompass rules about childhood in different countries and at different times. In this way, that which Boli-Bennett and Meyer take to be a constant—the boundary between legislation and constitution—could be treated as a variable.) To be sure, locating all the relevant documents from a 100-year period would be laborious, and, as Boli-Bennett and Meyer (p. 800) state, the analysis would be "complex." The workload could be reduced, however, by studying not all independent nations, but a sample; the nations could be stratified by two plausible explanatory variables used by Boli-Bennett and Meyer: (1) date of independence, and (2) centrality in the world system. Improvements in the childhood index and other indicators would, we believe, more than compensate for the reduction in the number of countries studied (see Ratner, forthcoming; Kagan et al., 1977, for discussions of this issue).

Coding rules. As noted, three of Boli-Bennett and Meyer's crucial variables—the childhood index and two measures of state authority— are based on the content analysis of constitutions. All three indicators of content are largely measures of the amount of detail in those constitutional provisions dealing with a given issue. For example, one of the components of the childhood index is an indicator of the "levels of education specified": a constitution is given a score of 0 on this indicator if education is not mentioned; a 1 if it is mentioned but if no more than one level is specified; and a 2 if two or more levels of education are specified (Boli-Bennett and Meyer, 1978:803). Similarly, the index of constitutionally defined state authority "simply sums the number of institutional areas under state jurisdiction and the number of administrative mechanisms available to the state to manage society" (p. 807).

What do these measures of content measure? There are at least two possibilities. First, they may measure ideologies of childhood and of state authority, as Boli-Bennett and Meyer claim. The degree of detail with which people deal with a subject probably indicates their degree of concern and the breadth of their aims.

Alternatively, the measures may gauge the inclination of constitution writers to go into detail. Boli-Bennett and Meyer show that the mean score on the childhood index has increased fairly steadily during the last 100 years. This result is consistent with the hypothesis that constitutions have become more specific during that time—possibly because provisions that formerly would have been written into ordinary legislation are now being written into constitutions. On the basis of the evidence presented, we cannot tell if Boli-Bennett and Meyer are measuring ideologies of childhood or an inclination to go into detail.

How does this ambiguity about what they are measuring affect our interpretation of their findings? We can conclude that their findings are consistent with one of their implicit hypotheses—that certain aspects of constitutions diffuse around the world. The problem is that we cannot tell, from the data, exactly what it is that is diffusing—ideologies of childhood, or the propensity of constitution-writers to go into detail, or government regulation.

This problem is especially apparent when we try to interpret the correlations between the childhood index and other variables presented in Table 3. The strong correlations are those between the childhood index and the indices of general state authority already mentioned. Boli-Bennett and Meyer (1978:800) claim that this shows that "childhood as political ideology reflects . . . the degree of authority over society assumed by the state" and (p. 801) that "the rules defining childhood . . . should be little affected by variations in the level of organizational complexity of national societies." In fact, these results are consistent with either ideologies of childhood or specificity of constitutions having the hypothesized relationships with other variables. For example, it is especially noteworthy that the highest correlations are those between indices of different dimensions of the content of constitutions—the childhood index and indices of state authority. This is exactly what we would expect to find if the different indices were, in fact, all imperfect measures of a single underlying variable—the specificity of constitutional provisions.

How could we resolve this ambiguity? One way would be to develop additional independent measures of state involvement in childhood, and to compare the new indicators to those of Boli-Bennett and Meyer. For example, Boli-Bennett and Meyer (1978:797; and similar statements on 810–1) suppose ". . . that, in the long run, the establishment of the ideology of modern childhood throughout the world lends strong support to the organizational implementation of dependent but protected childhood status." If this is the case—that is, *if* Boli-Bennett and Meyer's indices measure ideology, and *if*, as they suppose, ideologies will be implemented—then we would expect significant (lagged) relationships between their indices and variables gauging the implementation of relevant programs. (Implementation of ideologies of childhood could be measured, for instance, by levels of educational attainment, proportion of children working in manufacturing, and so forth.) Alternatively, if the indices measure specificity—and not ideologies of childhood or state authority—we would not find such relationships. Such a lack of relationship between the childhood index and an implementation index (coupled with strong relationships between the different dimensions of the content of constitutions) would lend great weight to the constitutional specificity hypothesis.

Thus, we could determine whether Boli-Bennett and Meyer's indices are valid indicators of the rules concerning childhood likely to be implemented. Our guess is that the relationship between indices of ideology found in constitutions and implementation will be weak; consider the civil liberties guarantees in the Soviet constitution, or the lack of rules about childhood in the United States Constitution. The relationships will probably be stronger, however, when other legal documents are taken into account.

Interpreting results. Boli-Bennett and Meyer (1978:798–9) assert that "general rules differentiating childhood and incorporating it as a distinct status in the structure of the state arise as part of the 'modern' (bourgeois and technical) ideology defining the nature of life and action. Two central elements of this perspective are . . . *the nature of individualism* and the *expansion of the state.*" They conclude (p. 810) that "the dominance of the ideology of differentiated and state-managed childhood reflects the rise of both individualism and the rationalized nation-state."

Boli-Bennett and Meyer appear to link the rise of childhood as a distinct status—particularly as dealt with by the educational system—with an increase in individualism. Their coding scheme appears to operationalize an odd notion of individualism, however. Consider their indicator of "state control of education," part of the childhood index. A constitution is assigned a score of 2, the highest possible score, if "the state has monopoly power over education: nonstate schools are prohibited" (Boli-Bennett and Meyer, 1978:802). The 1954 constitution of the People's Republic of China, an explicitly collectivist society, is assigned a score of 2 on this dimension (p. 802). If this indicator were a measure of individualism, we might expect a higher score to be given to constitutions in which education was required, and in which the individual was offered alternative forms of education from which to choose. But that is not the case.

Table 4 (Boli-Bennett and Meyer, 1978:809) presents the mean scores of the childhood index of different types of countries. "Communist-party dominant" countries have a mean score of 9.4, while "European Protestant" countries (including the United States) have a mean of 4.2. It is perfectly all right to give technical meanings to everyday words, but it defies common sense to suggest that an index reflects individualism stemming from the rise of bourgeois ideology when Communist countries get high scores and European and American Protestant countries get low scores. The childhood index is probably better seen as reflecting state acknowledgment of stages of the life cycle and social control over children.

One last point. Boli-Bennett and Meyer set themselves a difficult task—studying social, political, and ideological change by methodically content analyzing sample constitutions. Problems might have arisen no matter what they did. But they appear to have exacerbated their problems in two major ways: first, by relegating most of the discussion of a critical issue—the meaning of the legislation-constitution distinction—to a footnote; and, second, by claiming that "few researchers have yet tried to tackle legislation on a systematic comparative basis . . ." (Boli-Bennett and Meyer, 1978:800). We suggest they refer to Kochran (1973), Stetson and Wright (1975), Berk et al. (1977), Burstein (1978), and Ratner (1977; forthcoming). All deal extensively with the content analysis of legislation, and the latter three in particular include bibliographies of the vast political science literature on the subject.

We think that Boli-Bennett and Meyer's hypotheses are important and their aims worth pursuing. Because their indicators are not well thought through, however, their data do not support their conclusions. At this stage in the development of this type of research, it is especially important to draw on previous work so that we can sidestep the pitfalls surrounding the construction of sound measures of legal rules.

CONSTITUTIONS AS IDEOLOGY*

(REPLY TO RATNER-BURSTEIN)

In its evolution over the past three centuries, world society has constructed a global level of social reality in which highly expanded state authority is legitimated. Part of this process has involved an expansion of the linkages between states and individual citizens. The individual has come to be defined as possessing more and more rights and duties, in relation to collective society, as well as the personal qualities and capacities necessary to exercise these rights and fulfill these duties. This new, complex definition of the individual is increasingly organized around citizenship: the individual is a member of and agent for the state (Bendix, 1964; Swanson, 1971). There has been a progression from earlier definitions of the individual identified in relation to a religious or natural universe to the more recent rationalized definition of the individual as a citizen of the nation-state.

---

* Direct all communications to: John W. Meyer, Department of Sociology; Stanford University; Stanford, CA 94305.

World society has increasingly taken on a life of its own, transcending even the level of social organization of the dominant national societies, and it enjoys rather strong legitimacy, in part because of the formal equality among all nation-states in the present world. Its culture flows, as ideology, into the constitutive structures of national societies, in large part independently of the variations among local societies and economies.

We studied this process of the flow of ideology as it involves the development of state authority over childhood, a central part of the life of the individual. We showed that state authority over childhood is increasingly incorporated in national constitutions in a way that clearly reflects the influence of world society rather than of variations in national development. Indeed, the phenomenon occurs most comprehensively in weak peripheral nations, perhaps because they are the most dependent on world society and the least constrained by their own organizational histories.

The comments of Ratner and Burstein do not seem relevant to the general issue we analyzed, for the following reasons:

(1) Constitutions, which are quite general ideological depictions of state authority, are indeed most appropriate for our purposes. Our critics complain that these documents may be subject to prevailing world ideologies, but that was precisely our point: They are. Of course it would be useful to study other ideological documents (we are presently involved in doing so), but neither legislation nor administrative regulations are as suitable as constitutions for evaluating our theoretical perspective. Such other documents obviously reflect social organization processes other than ideology, though they have ideological aspects too.

(2) We did not argue that constitutional rules in particular countries are likely to be "implemented" but, rather, that prevailing world ideologies are likely to be incorporated both ideologically and organizationally. For instance, the expansion of educational enrollments is a world process largely independent of national variations (Meyer et al., 1977). But ideological adherence and organizational implementation do not necessarily occur at the same time or at the same rate: peripheral states that are most likely to adopt constitutional ideology as a mobilizing strategy are often slowest to adapt organizationally. Their structural weakness in world society underlies both processes.

The important point is that we studied constitutions in their own right as ideology, not under the naive assumption that ideological adherence in constitutions has automatic and immediate effects on concrete organizational structures.

(3) Constitutional rules are not functional alternatives to legislation or administration. There is a complex two-way relationship between ideological conformity to world society and state organizational efforts to give concrete form to such ideologies. For instance, American national legislation in the area of childhood has been greatly limited by the absence of constitutional authority for such legislation. More generally, our index of national constitutional authority over childhood (the Childhood Index) is correlated .30 (74 cases) with the Ramirez and Rubinson (1979) measure of central national controls over primary education, which is derived from quite different sources. These two distinct aspects of state structure therefore complement, rather than substitute for, each other.

(4) Constitutions indeed get more specific over time as they legitimate expanded state authority over more domains, including childhood. This reflects world society standards that go far beyond the whims of writing style, for actual state structures have enormously expanded their domains and controls over the same period (Meyer et al., 1975). Constitutional specificity or "wordiness" is a minor issue: constitutional length (in characters) in 1970 is correlated only .05 with the Childhood Index (139 cases, data from Boli-Bennett, 1976). For 1950, the figure is .23 (76 cases).

(5) We attempted no direct measure of national "individualism" and employed the notion only as an explanatory theoretical element which accounts for one aspect of the evolving world political culture.

Further, individualism (as we used the term) is not in opposition to collectivism. The modern world society dialectically elaborates both collective authority as vested in the state and the importance of the role of individuals and individual action, also increasingly vested in the state. Thus, socialist states expand the ideologies of both collective authority and the individual, and many new postsocialist states having great constitutional authority endow individual actors with extraordinarily expanded citizenship rights and duties. This phenomenon has been discussed at least since the work of Marshall (1948).

(6) We noted that there is little comparative research on our problem. Our critics cite a literature, and specific studies, that are not very relevant, consisting as they do of case studies of specific types of legislation, and comparisons among American states. There are few cross-national studies, and practically

no studies of organizational ideologies at the national and transnational levels.

ITEMS

■ BERT USEEM (The Boston Anti-Busing Movement) is a Postdoctoral Fellow at the Center for Research on Social Organization, University of Michigan. He recently completed a study of worker participation in the Bolivian revolution (forthcoming, as *Politics and Society*). His current research involves the nuclear-power controversy.

■ KENNETH A. BOLLEN (Comparative Measurement of Political Democracy) is an Associate Senior Research Scientist in the Societal Analysis Department of General Motors Research Laboratories. Currently, he is working on several projects in the area of international development and statistical problems of using ratio variables.

■ JAMES R. LINCOLN (Organizational Properties from Aggregate Data) is Associate Professor in the Department of Sociology, Indiana University, Bloomington. His current research interests concern interorganizational networks. He is engaged in a study of client flows and other relations between community agencies delivering services to youthful "status" offenders. He has also begun a project addressed to corporate interlocks and other ties relating large United States corporations. GERALD ZEITZ is Assistant Professor in the Department of Sociology, State University of New York (SUNY) at Stony Brook. He is currently researching two areas: (1) structural and individual determinants of morale in industrial organizations; and (2) development of nuclear-power industry in the United States. The intention is to determine to what extent interorganizational theory can be used to understand this development.

■ HERBERT BLUMER (Social Behaviorism and Symbolic Interactionism) is Professor Emeritus, Department of Sociology, University of California at Berkeley. Currently, he is working on "Analysis of the 'Social Situation'," "Limits of Structural Analysis," and "The Career of Social Movements."

■ CLARK MC PHAIL (*Ex Cathedra* Blumer or *Ex Libris* Mead?) is Associate Professor, Department of Sociology, University of Illinois at Urbana-Champaign. Presently, his research concentrates on the many aspects of "Crowd Behavior." CYNTHIA REXROAT is Assistant Professor, Department of Sociology, University of Florida. Her current research involves a study of racial differences in timing of the first birth and in wives' labor-force participation.

■ D. A. ANDREWS (Structural Intervention and Differential Association) is Associate Professor, Department of Psychology, Carleton University, Ottawa, Canada. Three topics occupy his current research: (1) psychosocial and organizational correlates and predictors of problem behaviors; (2) program evaluation as a means of investigating, experimentally, the causal and practical significance of and the links between social and behavioral theory; and (3) the selection and training of citizen volunteers for intensive vs. nonintensive probation supervision and their effects on the process and outcome of adult probation.

■ RONALD R. RINDFUSS (Education and Fertility . . . Roles Women Occupy) is Assistant Professor, Department of Sociology, University of North Carolina at Chapel Hill. His book, *Postwar Fertility Trends and Differentials in the United States*, written with James A. Sweet, was published in 1977 (New York: Academic Press). He continues work on various sociological aspects of the timing of fertility in the United States, as well as in Southeast Asia, and is preparing a monograph, *Age, Time and Fertility*, which summarizes the U.S. work. LARRY BUMPASS is Professor, Department of Sociology, and the Center for Demography and Ecology, University of Wisconsin-Madison. He is researching factors affecting the timing of fertility in the United States, Korea, and the Philippines. He is also studying children's experience with divorce. CRAIG ST. JOHN is a Ph.D. candidate, Department of Sociology, University of North Carolina. His research centers on patterns of residential segregation (concentration) in large urban centers, emerging, over time, as the metropolis expands in scale.

■ RONALD C. KESSLER (Social Class and Psychological Distress) is Assistant Professor, Department of Sociology, University of Michigan. With David Greenberg he is completing a monograph on the methodology of panel analysis. His other work focuses on the structural determinants of psychological well-being and mental illness. He is also working on an analysis of the stress-buffering effects of social support-systems. PAUL D. CLEARY is Assistant Research Professor, Graduate School of Social Work, Rutgers University. His present research concerns psychiatric epidemiology and factors related to the use of prescribed psychotropic drugs.

■ JON MILLER (Access to Interorganizational Networks) is Associate Professor, Department of Sociology and Acting Director, Laboratory for Organizational Research, University of Southern California. His current research concentrates on the effects of race, sex, and age (and their interactions) on the stratification of organizations and interorganizational systems; and on attempts to link treatment performance of social service delivery systems to their positions in community-based networks—an extension of the work published in this issue and being done in collaboration with James R. Lincoln, Indiana University.

■ ERICH WEEDE (Sociological Analyses of Income Inequality) is Associate Professor, Forschungsinstitut für Soziologie, Universität zu Köln. His current research is on Income Inequality and Economic Growth. Recent books: *Weltpolitik und Kriegsursachen im 20.* (Jahrhundert, München 1975); and, together with Dietmar Schössler, *West German Elite Views of National Security and Foreign Policy Issues*. Königstein/ Ts. 1978.

■ DR. CHARLES J. MORGAN (Comment on Quadagno) is the statistician and research design analyst for Region 10 of the Environmental Protection Agency and teaches occasionally in the Department of Psychology, University of Washington. His book, co-authored with Penelope J. Greene, *The Logic of Social Statistics*, is forthcoming from Wiley. His research currently involves (1) environmental quality; (2) computer simulation of natural selection and altruism, with special reference to the social definition of kinship in human societies; and (3) behavioral ecology of Eskimo societies.

■ LOIS M. VERBRUGGE (Comment on Gove and Hughes), is Assistant Professor of Biostatistics and Faculty Associate (Institute for Social Research), University of Michigan. Her chapter, "Sex Differentials in Health and Mortality," in A. H. Stromberg (ed.), *Women, Health, and Medicine*, is being published (1980) in Palo Alto, Calif: Mayfield. She is continuing her research in sex differences in health and mortality . . . particularly recent trends in sex differentials in the United States, and differences in the ways physicians diagnose and treat men and women patients.

■ DAVID MECHANIC (Comment on Gove and Hughes) is Professor of Social Work and Sociology in the Graduate School of Social Work, Rutgers University. His books, *Future Issues in Health Care* and *Mental Health and Social Policy* (2nd.ed.) are forthcoming. He is also researching the determinants of health behavior and psychological impairment.

■ RONNIE STEINBERG RATNER (Comment on Boli-Bennett and Meyer) is Research Director and Visiting Assistant Professor in the Center for Women in Government, SUNY at Albany. Her book *The Growth of Wage and Hour Standards Laws, 1900–1973: A Modest Magna Charta* is forthcoming from Rutgers University Press. She also edited *Equal Employment Policy for Women . . ., 1979,* from Temple University Press. Her work now is on comparative study of equal employment opportunity policy: impact of civil service procedures on occupational location; and the wage disparity, by sex, of public employees. PAUL BURSTEIN is Assistant Professor at Yale University, until June, 1980. His *Politics and Labor Markets: Causes and Consequences of the Passage of Equal Employment Opportunity Legislation* is forthcoming. His research is currently being done on the causes and consequences of the passage of equal employment opportunity legislation; and on social stratification and democratic political change.

BRANDEIS UNIVERSITY

THE FLORENCE HELLER GRADUATE SCHOOL

Applications are invited from individuals interested in full-time faculty appointments for 1980-81 and later, in:

- SOCIAL PLANNING and POLICY ANALYSIS
- SOCIOLOGY, with emphasis on the social context of policy issues
- LAW and SOCIAL POLICY
- ORGANIZATIONAL BEHAVIOR, emphasizing social policy implications

Candidates will be expected to teach core courses and offer additional courses in their specialty areas. They also will be expected to engage in research relevant to their substantive areas. Demonstrated capacity to generate outside sources of support is required. Applicants should have a Ph.D. or its equivalent, be familiar with current social policy issues, and have an interest in participating in a multidisciplinary approach to social policy analysis and social welfare. Rank is open.

The Heller School offers a Ph.D. in Social Welfare and a Master's Degree in Human Services Management. Graduates of the School have assumed high level positions as researchers, planners, policy analysts, managers, and academicians.

Please send applications to Ms. Bibeau, The Heller School, Brandeis University, 415 South Street, Waltham, MA 02254.

An Affirmative Action / Equal Opportunity Employer

THE AMERICAN SOCIOLOGIST

(James L. McCartney, *Editor*)

(Quarterly—ISSN 0003-1232)

The American Sociologist contains major articles analyzing sociology as a profession and as a discipline. Included are papers on such professional concerns as the use of sociological knowledge and skills in academic and non-academic settings; the conditions of work and maintenance of professional standards; the ethical, practical, and intellectual issues related to research; practical problems affecting sociologists as professionals (e.g., taxes, publication, copyright); ideological issues related to the development of new perspectives.

Recent issues have included articles on:

- *Field Work and the Protection of Human Subjects* DUSTER, MATZA & WELLMAN
- *Filthy Pictures or the Case of the Fraudulent Social Scientist: Unmasking the Phony Expert,* ST. GEORGE & McNAMARA
- *Representations of Merton's Theory of Anomie* HILBERT & WRIGHT
- *Universality of Science and the Question of National Sociologies,* HILLER

THE ECONOMIC CRISIS AND AMERICAN SOCIETY

MANUEL CASTELLS

A Marxist critique of American society and economy which pinpoints the new forms of the capitalist mode of production and the contradictory nature of its class relations as the root of our problems. Taking a hard look at the recent crisis afflicting Western economies, Manuel Castells suggests that the very structures that fostered economic growth since 1945 are the same structures that are now undermining these economies. Instead of dogmatic solutions, he proposes a profound transformation of the logic of investment and modification of the power relationships between social classes as eventual ways leading towards a more humane society. Cloth, $18.50. Paper, $5.95

THE MAKING OF A STORMTROOPER

PETER H. MERKL

Singling out members of the most actively militant wing of the Nazi movement, Peter Merkl explores the historical, sociological, and personal factors that motivated their attitudes and behavior. The principal resource for his inquiry is Theodore Abel's collection of 581 autobiographical statements of early Nazis. What emerges is an integrated picture of the motives of the stormtroopers and the circumstances under which they fostered the transition from a fringe movement to a mass movement and hence to the success of Adolf Hitler in taking over the country. A Disturbing, Completely Documented Study
of the Invasion of Privacy in America

THE
POLITICS
OF
PRIVACY

BY JAMES RULE, DOUGLAS McADAM,
LINDA STEARNS AND DAVID UGLOW

The right to privacy in America continues to diminish. The computers of banks, insurance companies, credit rating services, corporations and government agencies hold vital data on the private lives of virtually everyone.

THE POLITICS OF PRIVACY is a fully documented status report on this "Big Brother" phenomenon of modern life and the impact it may have on our society. It is disturbing, frightening, yet absolutely essential reading.

The Sociology and Politics of Development A Theoretical Study
BAIDYA NATH VARMA City College, City University of New York

In answering the crucial question of how social change should be guided in the developing countries, Professor Varma examines some of the models that have been used in the past. He provides extensive summaries of the views on modernization of theorists in various disciplines, including sociology, politics, economics and anthropology, and focuses on the relevancy of these theories as they relate to decisions affecting the economy, the polity, the educational system, and the bureaucracy in a developing society.
International Library of Sociology $25.00

The Sociology of Belief Fallacy and Foundation
KEITH DIXON Simon Fraser University, British Columbia

Keith Dixon contends that traditional and contemporary formulations of the sociology of knowledge involve a series of fallacies, and argues that the sociology of knowledge and belief needs to give due weight not only to the social and historical location of thought, but to the independently operative logic of various human discourses. **Monographs in Social Theory** $20.00, paper $10.00

Marx and Mead Contributions to a Sociology of Knowledge
TOM W. GOFF Mount Allison University, New Brunswick

It has often been suggested that a resolution of issues generated by the sociological study of ideas might be reached through a synthesis of specific insights to be found in the works of Karl Marx and George Herbert Mead. This study originated in an investigation of this hypothesis, particularly as it bears on the central issues of sociological relativism. **Monographs in Social Theory** $18.50

The Articulation of Modes of Production
Essays from 'Economy and Society'
EDITED BY HAROLD WOLPE University of Essex

This collection of essays is primarily concerned with the concept of articulation of modes of production and with the analysis of a number of different social formations utilizing this concept. The emphasis is on the relationship between capitalist and other modes of production. **Original paperback** $18.50

Lesbians, Women and Society
E.M. ETTORRE Institute of Psychiatry, London

In presenting an analysis of lesbianism as this phenomenon has developed from an 'individual deviance' to a social movement or political practice, this book establishes the links between this specific group of women and women in general, and between lesbians' struggles and the wider fight for women's rights.

CAMBRIDGE

Computers and Social Change

Murray Laver

Laver addresses himself to the often unintended effects of the computer age on education, employment, and leisure, reviewing the social and human consequences of the increased availability of information to governmental and commercial organizations. *Cambridge Computer Science Texts 10*
Hardcover $19.95 Paper $6.95

Spectacles and Predicaments

Essays in Social Theory

Ernest Gellner

Essays deal with the basic images through which we interpret humanity, with the basic nature of knowledge, and with substantive socio-political questions. $34.00

Rational Action

Studies in the Philosophy of the Social Sciences

Ross Harrison, Editor

Martin Hollis, Bernard Williams, Richard Tuck, John Maguire, Ross Harrison and others deal with the concept of rationality and the interrelations among rationality, belief, and desire in the explanation of human action. $19.95

The Tragedy of Enlightenment

An Essay on the Frankfurt School

Paul Connerton

Connerton conveys an overall sense of the continuities and discontinuities in the concerns of representative members of the School, showing how the experience of Fascism shaped their interpretation of modern society as a whole and setting their work in the context of German intellectual history. *Cambridge Studies in the History and Theory of Politics*
Hardcover $24.95 Paper $7.95

Naturalism and Social Science

A Post-Empiricist Philosophy of Social Science

David Thomas

This application of recent developments in the philosophy of science to an understanding of social science includes detailed case studies of such authors as Althusser, Durkheim, Kuhn, and Winch, and areas of work including ethnomethodology, the sociology of magic and religion, and Marxist views of consciousness and revolution. *Themes in the Social Sciences*
Hardcover $32.50 Paper $11.50

The Economics of Individual and Population Aging

Robert L. Clark and Joseph J. Spengler Hardcover $22.50 Paper $7.95

Sociolinguistics

R. A. Hudson Hardcover $34.50 Paper $10.95

Measurement in the Social Sciences

The Link Between Theory and Data

Richard A. Zeller and Edward G. Carmines

In this theoretical and methodological introduction to the measurement techniques used in social science research, Zeller and Carmines thoroughly explain the assumptions, limitations, and interpretations of these techniques as they discuss the ways in which measurement principles can be effectively applied in research. Hardcover $26.95 Paper $7.95

Who Should Know What?

Social Science, Privacy and Ethics

J. A. Barnes

Barnes looks at changes in the conduct of social research since the early nineteenth century, discussing the ethical and political obligations of social scientists in collecting data and publishing their findings. His incisive study reveals the precariousness of the survival of a truly democratic social science. Hardcover $17.50 Paper $4.95

Comrades and Christians

Religion and Political Struggle in Communist Italy

David I. Kertzer

Drawing from his own participant-observation research conducted in a working-class quarter of Bologna, Kertzer effectively blends case studies, individual portraits, and sociopolitical analysis in his examination of the ways in which the people actually experience their divided loyalties, torn between a tradition of anti-clericalism and a Church that decries Communism as incompatible with Catholicism. Hardcover $24.95 Paper $6.95

The Western Isles Today

Judith Ennew

Dr. Ennew traces social changes in the Western Isles of Scotland from the beginning of the nineteenth century to the present. She finds that agricultural practices, political activity, and family life are all affected by the conflict between Gaelic, Puritan, and English norms, and argues that these are not related to the staple sociological divisions between tradition and modernity or state and community. *Changing Cultures* Hardcover $21.50 Paper $5.95

The New International Division of Labour

Folker Fröbel, Jürgen Heinrichs, and Otto Kreye. Translated by Pete Burgess

The Third World Reassessed

Elbaki Hermassi

Recent developments in the Third World have led to a polarization in scholarship, calling into question theories associated with Development. Hermassi discusses the directions Third World societies are evolving; how the Social Sciences should be applied to societies for which they were not originally designed; and how the Western Social Sciences can be de-parochialized by informing them with the experience of the Third World.
$15.00

Asian and African Systems of Slavery

Edited by James L. Watson

In this comparative analysis, the contributors emphasize indigenous systems of exploitation and their interconnections with the worldwide traffic that developed during the eighteenth and nineteenth centuries. Relatively little has been published on Asian forms of slavery, which are here contrasted with African modes.
$20.00

The Changing Academic Market

General Trends and a Berkeley Case Study

Neil J. Smelser and Robin Content

In recent years there has been a dramatic shift in the demand for academic services. Smelser and Content examine the new dynamics of the academic marketplace and, in particular, the processes of recruitment. To underscore their general analysis, they describe the way the sociology department at the University of California, Berkeley, carried out its search for three junior faculty in 1975-76.
$14.00

The Implementation Perspective

A Guide for Managing Social Service Delivery Programs

Walter Williams

Implementation is a fundamental management problem at all levels of government. Williams presents a new decision-making rationale as a basic guide to program management where the central focus of policy must be the point of service delivery.
$12.50 cloth, $4.50 paper

People Studying People

The Human Element in Fieldwork

Robert A. Georges and Michael Owen Jones

Information about the human element in field-based studies is usually subordinated to discussions of fieldwork "methods." The authors develop the thesis that an appreciation of fieldwork as a unique mode of inquiry depends upon an understanding of the role the human element plays in it.

CHARLES C THOMAS • PUBLISHER

New! **SPIRITUAL WELL-BEING OF THE ELDERLY** *edited by* **James A. Thorson,** *Univ. of Nebraska, Omaha, and* **Thomas C. Cook, Jr.,** *National Interfaith Coalition on Aging, Athens, Georgia. (33 Contributors)* Contributors from such disciplines as psychology, social work, philosophy, theology, and nursing discuss the importance of spiritual well-being to the quality of life of the elderly. Practical applications are related to the research findings presented. *'80, 260 pp., 1 table, $22.50*

New! **THE BOTANY AND CHEMISTRY OF HALLUCINOGENS (2nd Ed.)** *by* **Richard Evans Schultes,** *Harvard Univ., Cambridge, Massachusetts, and* **Albert Hofmann,** *Basel, Switzerland. Forewords by* **I. Newton Kugelmass** *and* **Heinrich Klüver.** This updated edition continues to explore the botanical distribution and chemistry of plants of known, possible, and dubious hallucinogenic potential. Ethnobotanical, historical, pharmacological, and psychological aspects are also covered. *'80, 464 pp., 162 il., 10 tables, $28.75*

SOCIETY'S VICTIM—THE POLICEMAN: An Analysis of Job Stress in Policing (2nd Ptg.) *by* **William H. Kroes,** *Institute for Stress Management, Los Angeles.* This book brings the serious problem of police stress into the public's awareness and offers suggestions for reducing such stress. Chapters cover specific police stressors, the effects of stress, and stress reduction. *'77, 144 pp., 14 il., 4 tables, $12.50*

OLDER PERSONS AND RETIREMENT COMMUNITIES: Case Studies in Social Gerontology *by* **Jerry Jacobs,** *Syracuse Univ., Syracuse, New York.* This comparative ethnographic study of three different kinds of retirement settings explains why patterns of social interaction developed as they did within each setting. Suggestions for improving ineffective interaction are delineated. *'75, 144 pp., cloth-$13.50, paper-$8.75*

New! **THE RIGHTS OF THE MENTALLY RETARDED/DEVELOPMENTALLY DISABLED TO TREATMENT AND EDUCATION** *by* **Issam B. Amary,** *Marshall State School and Hospital, Marshall, Missouri.* This text explains and encourages recognition of rights of the mentally retarded/developmentally disabled to marriage, family life, and social interaction; to due process of law, dignity, respect, and freedom; to personal possessions and proper clothing; and to high quality treatment, comprehensive education, and vocational rehabilitation. Pertinent professional and special services are delineated. *'80, 216 pp., 6 il., $17.50*

WOMEN WHO DRINK: Alcoholic Experience and Psychotherapy *edited by* **Vasanti Burtle,** *Los Angeles. Foreword by* **Phyllis K. Snyder, Jan DuPlain** *and* **George Staub.** *(14 Contributors)* Contributors from a variety of disciplines explain in what ways the female alcoholic's experience differs from that of the male and offer gender-specific therapy suggestions. Chapters cover drinking patterns of women alcoholics, training needs of alcoholism caregivers, women and sex, skid row women, alcoholism among Third World women, family counseling issues, and related subjects. *'79, 304 pp., 3 il., 9 tables, $21.00*

CHANGING SEXUAL VALUES AND THE FAMILY *edited by* **G. Pirooz Sholevar,** *Hahnemann Medical College and Hospital, Philadelphia. (22 Contributors) '77, 192 pp., 5 il., $15.25*

LANGUAGE PATTERNS OF POVERTY CHILDREN *by* **Nicholas J. Anastasiow,** *Indiana Univ., Bloomington, and* **Michael L. Hanes,** *Univ. of Florida, Gainesville.* Theoretical concepts and educational prescriptions are included in this psycholinguistic study of the cultural/dialectal language patterns of poverty children. *'76, 176 pp., 1 il., 4 tables, $15.25*

Why do you behave the way you do?

Social Traps

John G. Cross and
Melvin J. Guyer

Most of us like to think of ourselves as rational people. Yet we continually do irrational things. We know of the health hazards involved in substance abuse, yet we continue to smoke and drink and overeat. We know the difference between superstition and real danger, yet we refuse to walk under ladders and will not cross the path of a black cat. Just as a mousetrap entices its prey with attractive bait and the promise of reward, so are people in social situations drawn into behavioral traps. And just as the trap destroys the mouse, so does the individual caught in the trap find himself threatened with the consequences of his actions. *Social Traps* is an analysis of our irrational moments, drawn from game theory, economics, and psychological learning theory, offering us a mirror by which to measure our often self-destructive behavior.

Manufacturing the News
By Mark Fishman

News organizations cover the world mainly through "beats," which tend to route reporters through governmental agencies and corporate bureaucracies in their search for news. It is part of the function of such bureaucracies to transform complex happenings into procedurally defined cases, and the information they produce for newsworkers represents their own bureaucratic reality. According to Fishman's research, journalists tend to view this reality as hard fact, while accounts from other sources are treated as unconfirmed reports. Under this system, Fishman concludes, news stories will continue to support the interests of the status quo independently of the attitudes and intentions of reporters, editors, and news sources.

FEAR OF SCIENCE — TRUST IN SCIENCE

Conditions for Change in the Climate of Opinion

Edited by Andrei S. Markovits, *Wesleyan University*, and Karl W. Deutsch, *Harvard University*

These contributions from international scholars, researchers, and politicians examine the relationships between science, scientists, technology, and the public in the past, during the present, and toward the future.

ca. $20.00

DECENTRALIZATION

Toward a Rational Theory

Manfred Kochen, *University of Michigan*, and Karl W. Deutsch, *Harvard University*

This book describes a theory of systematic planning for the future of large service organizations incorporating basic concepts and mathematical models for decentralization and stressing common aspects of different service networks. $27.50

THE CRIMINAL JUSTICE AND MENTAL HEALTH SYSTEMS

Conflict and Collusion

Kent S. Miller, *Florida State University*

This study of the amalgamation of the criminal justice and mental health systems suggests that these events do not reflect a move away from the therapeutic state and that any emerging relationship between the two systems is a benefit to both.

ca. $17.50

OXFORD

THE JEW IN THE MODERN WORLD
A Documentary History

Edited by PAUL R. MENDES-FLOHR, Hebrew University, and JEHUDA REINHARZ, University of Michigan. "An excellent, exhaustive, and many-sided collection." — Jacob Katz. "A rich compilation of sources which illuminate the problems of the modern Jew over the last 200 years.... An impressive work of scholarship." — Gerson D. Cohen. This sourcebook of over 200 primary documents — annotated and placed in their historical context — illuminates social, political, and cultural aspects of Jewish history from the 18th century through the early 1950s. 544 pp., $25.00

THE MIDDLE EAST
A Political and Economic Survey
New Edition

PETER MANSFIELD. Called "a standard reference for students of the Middle East from its first publication in 1950" (**Choice**, on the fourth edition in 1973), this extensive survey covers the geography, natural resources, history, and politics of the Middle East before the Crusades and then concentrates on the current problems of pan-Arabism, Palestine, and Iran and the significance of the Middle East in East West relations. It includes an account of Arab political movements and a detailed analysis of the role of oil in the world economy and international diplomacy.
592 pp., $29.95

A CRISIS OF IDENTITY
Israel and Zionism

DAN V. SEGRE, Haifa University. Tracing the history behind Israel's present political and cultural crises from the nineteenth century to today, Segre challenges the traditional view that judges Israel exclusively in relation to the West. He shows how Israel's position between Western and non-Western poles inhibits its spiritual and cultural independence and says that emancipation through imitation of the West is little more than self-colonization.
192 pp., $14.95

CLASS
Image and Reality in Britain, France, and America Since 1930

ARTHUR MARWICK, The Open University, London. Are class distinctions diminishing or disappearing? In this provocative, wide-ranging historical overview Marwick compares American, French, and British society since the Depression and concludes that in all three, class is still an important factor. Showing how class has changed as a result of economic and technological developments and social and political upheavals, Marwick reveals that since 1930, America has become much more like Europe. 350 pp., $14.95

JOURNAL OF
HEALTH & SOCIAL BEHAVIOR

(Howard B. Kaplan, Editor)

(Quarterly—ISSN 0022-1465)

JHSB publishes reports of empirical studies, theoretical analyses, and synthesizing reviews that employ a sociological perspective to clarify aspects of social life bearing on human health and illness, both physical and mental. Its scope includes studies of the organizations, institutions, and occupations devoted to health services, as well as studies of the behavior of actual and potential recipients of these services.

Recent issues contain reports on:

Social Class and the Use of Professional Help for Personal Problems: 1957 and 1976, RICHARD A. KULKA, JOSEPH VEROFF & ELIZABETH DOUVAN

Health Occupations in Israel: Comparative Patterns of Change During Socialization, JUDITH T. SHUVAL AND ISRAEL ADLER

Occupational Stress and Health Among Factory Workers, JAMES S. HOUSE, ANTHONY J. McMICHAEL, JAMES A. WELLS, BERTON H. KAPLAN, & LAWRENCE R. LANDERMAN

The Functional Importance of Sex Roles and Sex-Related Behavior in Societal Reactions to Residual Deviants, WILLIAM A. RUSHING

Stress, Social Status, and Psychological Distress, RONALD C. KESSLER

Announcing Two Volumes in the
STUDIES IN SOCIAL DISCONTINUITY Series

THE MODERN WORLD-SYSTEM II

Mercantilism and The Consolidation of The European World-Economy, 1600–1750

By IMMANUEL WALLERSTEIN

Critical Praise for The Modern World-System I —"I can say without hesitation that it is the finest book of analytic history that I have read in the last ten years. That Europe had formed a world-economy around herself historians knew, but only in general. What they had never thought about with the keenness and intelligence which characterizes Wallerstein's thought is that this entity provides a new framework for the subject of European history, that it is compelling, a new explanation, a new classification, indeed a revolutionary one, of received knowledge and current thought. . . ." —*FERNAND BRAUDEL*

This second volume of the *Modern World-System* continues the story of the historical development of the capitalist world-economy. Whereas Volume I treated the genesis of the system in the "long" and inflationary sixteenth century, this volume treats the consequences of the economic stagnation of the seventeenth century.

CONTENTS: INTRODUCTION: Crisis of the Seventeenth Century? The B-Phase: Dutch Hegemony in the World-Economy. Struggle in the Core—Phase I: 1651–1689. Peripheries in an Era of Slow Growth. Semipheripheries at the Crossroads. Struggle in the Core—Phase II: 1689–1763. Bibliography. Index.

HARDCOVER EDITION:

MEDIATION AND SOCIETY

Conflict Management in Lebanon

By CATHIE J. WITTY

A volume in the STUDIES ON LAW AND SOCIAL CONTROL Series

Mediation and Society is a theoretical and empirical inquiry into the nature of mediation and its relation to people, communities, and social systems. This comparative legal analysis is based on two comparative case studies—one Lebanese and the other American. It develops and illustrates a general theory of mediation and also addresses concrete issues of social and legal planning.

—CRIMINOLOGY FROM AN ANARCHIST PERSPECTIVE—

THE STRUGGLE TO BE HUMAN: CRIME, CRIMINOLOGY AND ANARCHISM

By

LARRY TIFFT
Central Michigan University

DENNIS SULLIVAN
College of St. Rose

The Struggle To Be Human is a foundational work which attempts to restore to human consciousness a more fundamental understanding of the conditions of social life, maintaining as it does that human survival and continuity are not insured by violence or power or institutions derived from the state, or its certifying professions, but through human competencies and usefullness derived from cooperation and mutual aid.

The Struggle To Be Human emerges amidst the recurring failure of both academic and marxist sociologies to provide insight into ways in which we can live together harmoniously. It links the issues of social harm and punishment to scarcity and the basic human struggle to be free, and provides an incisive critique of the institutions of law, the state and certifying administrative systems. Also, it provides some historical insights into how both academic and marxian analyses, by their insistence upon the centrality of the State, continue to trade away the possibility of present human fulfillment and community for a managed, power-based existence.

Notice to Contributors

A processing fee of $10 is required for each paper submitted, except for comments; such fees will be waived for student members of ASA. A check or money order, made payable to the American Sociological Association, should accompany each submission. The fee must be paid in order for the review process to begin.

The length of an *ASR* paper is generally ten (10) printed pages or thirty (30) typed pages. However, the *ASR* is happy to accept manuscripts up to fifty (50) typed pages in length for review. We also are interested in receiving manuscripts for a Research and Notes Section.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose only compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, *the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.*

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using *"ibid.," "op. cit.," or "loc. cit."* Examples follow:

1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) . . ."]

B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)

If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.

Examples follow:

1. *Books:* Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch
   1970 Ex-Pastors. Philadelphia: Pilgrim Press.
   U.S. Bureau of the Census
   1960 Characteristics of Population. Volume 1. Washington, D.C.: U.S. Government Printing Office.
   Bernard, Claude
   [1865] 1957 An Introduction to the Study of Experimental Medicine. Tr. Henry Copley Greene, New York: Dover.
2. *Periodicals:* Conger, Rand
   Forthcoming "The effects of positive feedback on direction and amount of verbalization in a social setting." Pacific Sociological Review.
   Merton, Robert K.
   1963a "The ambivalence of scientists." Bulletin of The Johns Hopkins Hospital 112:77–97.
   1963b "Resistance to the systematic study of multiple discoveries in science." European Journal of Sociology 4:237–82.
3. *Collections:* Davie, M.
   1938 "The pattern of urban growth." Pp. 133–61 in G. Murdock (ed.), Studies in the Science of Society. New Haven: Yale University Press.

See recent issues for further examples.

Editorial Assistant: HELEN CURLEY

Executive Officer: RUSSELL R. DYNES

SCOPE AND MISSION OF AMERICAN SOCIOLOGICAL REVIEW: The *American Sociological Review* publishes work of interest to the discipline in general, new theoretical developments, results of research that advance our understanding of the most fundamental social processes, and important methodological innovations. Like other publications of the Association, emphasis is given to exceptional quality. Unlike the more specialized journals of the Association, the *American Sociological Review's* primary focus is on whatever has the most general bearing on the knowledge of society.

Concerning manuscripts, address: Editor, *American Sociological Review,* Department of Sociology, University of Illinois, Urbana, Illinois 61801. (217) 333-6515.

The *American Sociological Review* (ISSN 0003–1224) is published at 49 Sheridan Avenue Albany, New York, bimonthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office

Copyright © 1980 American Sociological Association.

Annual membership dues of the American Sociological Association, $20–$120 ($10 of this amount may cover a subscription to the *American Sociological Review*); Associate, $25; International Associate, $25; Student Associate, $12.

Application for membership and payment of dues should be made to the Executive Office. Subscription rate for members, $10; nonmembers, $15; institutions and libraries, $30; nonmember students, $10. Single issue, $4.

New subscriptions and renewals will be entered on a calendar year basis only.

Change of address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

Concerning advertising, changes of address, and subscriptions, address: Executive Office, American Sociological Association, 1722 N Street, N.W., Washington, D.C. 20036.

Claims for undelivered copies must be made within the month following the regular month of publication. The publishers will supply the missing copies when losses have been sustained in transit and when the reserve stock will permit.

Second class postage paid at Washington, D.C. and additional mailing offices.

AMERICAN SOCIOLOGICAL REVIEW

DEPENDENCE, INEQUALITY, AND THE GROWTH OF THE TERTIARY: A COMPARATIVE ANALYSIS OF LESS DEVELOPED COUNTRIES*

PETER B. EVANS
Brown University

MICHAEL TIMBERLAKE
Memphis State University

American Sociological Review 1980, Vol. 45 (August):531–552

High levels of economic inequality found in less developed countries have been attributed to the penetration of their economies by investments of multinational enterprises based in more developed nations of the West. This attribution has been widely supported by both historical and quantitative research. There are several interpretations concerning why this might be so, but the one offered here is that foreign investments cause high levels of inequality by distorting the evolution of the labor-force structure. It is suggested that Third World economies penetrated by foreign capital will have unusually rapidly growing proportions of the labor force employed in the tertiary, and it is growth of this proportion which mediates some of the effects of dependence on inequality. Our quantitative analysis of cross-national data (a) corroborates previous research linking dependence to inequality, (b) indicates that dependence is associated with growth of the tertiary, and (c) suggests this is one important link between dependence and inequality.

Watching a superfluous human operator run an automatic elevator is an experience shared by almost everyone who has lived in or visited Third World countries. The experience is more than just a curiosity; it exemplifies a central social dilemma facing Third World countries. The elevator operator's time is valued on the basis of a combination of the "productivity" of the task and the difficulty of finding a replacement. Both are negligible—and so is the wage attached to the job. In consequence, the elevator operator must, in all likelihood, work 70 or 80 hours a week for a wage that does not even insure food and shelter.

The poverty of the elevator operator is, of course, no more severe than that of peasants and agricultural laborers in rural areas, but it is, in at least one sense, more discouraging. It is a poverty situated in the high-rise heart of the "modern" sector of underdeveloped economies. While the proportion of the labor force locked into the poverty of the traditional rural sector can be expected to shrink over time, the proportion located, like the elevator operator, in the urban tertiary sector is likely to grow. The elevator operator is a disturbing example precisely because of the juxtaposition of modernity and poverty.

Other aspects of the elevator operator's situation are also typical and disturbing. The elevator is automatic because the technology that went into its production was created in a developed country where an elevator which really needed an operator would be considered an expensive anachronism. Even if a multinational corporation did not produce the elevator, it almost certainly licensed the technology that was used to produce it. The operator's plight exemplifies one of the dilemmas that poor countries face in trying to deal with the technology produced by rich countries and with the multinational corporations that control this technology. Finally, the elevator operator's situation,

like that of domestic servants and others in the tertiary sector, epitomizes the disparities of life chances that are characteristic of societies. Many of the people who ride in the elevator probably make more in a day than the operator does in a month.

The quiet plight of the elevator operator brings together three generally acknowledged features of the current course of development of Third World countries: (1) Much larger proportions of the labor force are employed in the service or tertiary sector than were employed in currently developed countries at similar levels of industrial development. (2) The growth of industry is accompanied by an influx of foreign capital and by increasing dependence on foreign technology. (3) Levels of inequality are substantially in excess of those found in developed countries.

We cannot offer a solution to the elevator operator's plight, but we hope to contribute something to the way in which it is understood. Specifically, we will argue that rapidly growing tertiary sectors, high levels of dependence on foreign investment, and high levels of inequality are empirically associated in Third World countries, or at least were empirically associated during the sixties. The evidence we will present suggests that countries which were hosts to large amounts of foreign investment (relative to their wealth and population) were likely to experience both high levels of inequality and rapid growth of tertiary employment. While we cannot claim that our data are sufficient to prove causal linkages, our findings must certainly be considered reinforcement for those who argue that foreign investment has helped cause high levels of inequality by distorting the distribution of the labor force.

Dependence, Inequality, and the Growth of the Service Sector

Of the connections we will try to make, the one between foreign investment and inequality has been best explored in the literature. It has been argued, on the basis of case studies and theory, that penetration by international capital and dependence on the international market are associated with the generation of an inegalitarian model of development (cf. Dos Santos, 1970; Frank, 1967; Barnet and Muller, 1975; Amin, 1976; Cardoso and Faletto, 1979; Evans, 1979). Beginning with Cutright's (1967) finding that reliance on foreign trade was associated with higher levels of inequality, the assertions of the *dependendistas* have been corroborated by a number of different quantitative studies.

Galtung (1971:110), using a measure of "trade composition," found that reliance on exports of primary products and reliance on trade with a single partner were highly associated with higher levels of sectoral income inequality. Jackman (1975) replicated Galtung's "trade composition" findings. Chase-Dunn (1975) has shown that reliance on foreign direct investment was associated with income inequality and Rubinson (1976) replicated his findings. A recent review of the literature (Bornschier et al., 1978) shows the relation between dependence and inequality to be one of the most robust quantitative, aggregate findings available. Subsequent work continues to support their conclusion (e.g., Hout, 1979).

What is needed is better understanding of the processes which account for the connection between dependence on foreign capital and higher levels of inequality. Earlier theorists of imperialism, like Paul Baran (1968), might have argued that the relationship occurred because foreign capital supported "semifeudal" or *comprador* elites and impeded industrialization. In the seventies it seemed equally plausible to argue, as Bill Warren (1973) did, that foreign investments are likely to be associated with the intensification of capitalist accumulation in the Third World. Since it is generally acknowledged that the highest levels of inequality occur at intermediate rather than at the lowest levels of development (Adelman and Morris, 1973; Paukert, 1973; Cline, 1974), the nature of capitalist accumulation rather than the absence of growth is a more likely place to look for the connections between dependence and inequality.

If dependence exacerbates inequality, it is likely to be because of the *kind* of growth it fosters rather than because it entirely suppresses growth. Among the characteristics of the modern sector, created under the aegis of foreign capital, that might be related to inequality, the growth of the tertiary is a promising possibility.

The relation between the growth of the tertiary and foreign direct investment has been much less thoroughly explored than the relation between dependence and inequality. There are, however, a number of arguments which provide the basis for connecting the two, at least hypothetically. First, foreign direct investment enhances the possibility of the transfer of capital intensive productive techniques. Barnet and Muller (1975:166) put it most forcefully when they say that, "The one characteristic of global corporate technology with the most devastating consequences for poor countries is that it destroys jobs." We do not want to overstate this argument by suggesting that multinational managers can be distinguished from local managers of capital by a perverse, economically irrational proclivity for job-destroying technologies. However, it seems likely that a connection exists between the strength of ties with foreign capital and the existence of a general bias (shared by local firms) toward capital-intensive techniques. At the very least, we agree with Stewart's (1977:87) statement that "within the limited choice that is available more recent and capital intensive techniques are often selected than is strictly necessary."

Capital-intensive industry means that the secondary sector cannot absorb the growing numbers of people leaving the rural areas. In addition, the size of the exodus from the rural areas depends in part on a bias toward the underutilization of labor in agriculture. Numerous studies of Latin American agriculture have demonstrated the relation between the existing organization of agrarian landholdings and inability of agriculture to provide incomes for the rural population (e.g., Feder, 1971; Barraclough and Domike, 1966; Cline, 1970). R. Paul Shaw (1976:20) argues that the organization of agricultural landholdings is "the major cause of a misallocation of human resources away from potentially productive agricultural areas." While underutilization of rural labor is usually attributed to the traditional *latifundia* owners, an equal bias toward excessively "labor saving" agrarian strategies may also be characteristic of multinational firms. Foreign investment in agriculture is likely to result in capital-intensive rural enterprises which absorb relatively little labor themselves and take land away from peasant cultivators. In Brazil in the early seventies, for example, gigantic foreign-owned cattle ranches were set up in the states of Para and Mato Grosso, employing few people and expelling communities of peasant farmers (see Davis, 1978).

Finally, multinational corporations are likely to exacerbate what Todaro (1969) has called the "city lights effect." Todaro suggests that rural dwellers will be willing to migrate to urban *slums* as long as they have the expectation of eventually finding employment that will provide high incomes—relative, that is, to the incomes they know are possible in their present rural living areas. Their expectation—and whether they act on it—obviously depends on what information they receive about the modern sector. Multinationals have a proven effectiveness in generating demand for modern consumer goods even in the poorest, most "traditional" segments of Third World societies (see, e.g., Ledogar, 1975). Armed with an intensified desire for modern consumer goods and an unrealistic media-generated expectation of the extent to which those goods are consumed by city dwellers, the rural citizen becomes an even more likely candidate for migration to the city and entry into a marginal job in the urban tertiary sector.

While foreign investments are only one contributing element in this process, it is not unreasonable to expect that high levels of foreign economic penetration will be associated with more stress on the quest for modern consumer goods which, in the absence of expanding employment opportunities in the secondary sector, will be associated with what Amin (1976:260–70) has labeled the "hypertrophy of the tertiary." It is well established that currently developing countries tend to have larger tertiaries than early industrializers (Timberlake, 1979; Jakobson and Prakash, 1971). Soares (1969:194) notes that, at the point in the industrialization process when about half the labor force was in agriculture, about two-thirds of the rest of the labor force was in the secondary sector in early industrializers, but it is the tertiary sector of currently developing countries that contains the majority of the nonagricultural labor force. What is less well established is how the growth of the tertiary might in turn be related to inequality.

Some would argue against postulating such relationship. Lisa Peattie (1975), for example, has stressed the fact that even in the "informal" service sector of urban slums there are possibilities for making reasonable incomes. Unfortunately, while examples of successful petit bourgeois commercial entrepreneurship in slum communities may be impressive as individual cases, they have little to do with the overall quantitative impact of the growth of the tertiary. A more aggregate level argument might be based on average incomes in tertiary and primary sectors. Since tertiary incomes are generally higher, it could be argued that a transfer of impoverished rural workers from agriculture to the tertiary will increase their wages and, thereby, diminish inequality. This argument, however, does not take into account the importance of the tertiary within sector inequality in shaping the total income distribution. Because the tertiary includes everyone from the most highly paid doctors and lawyers to the most poorly paid domestic servants and street vendors, its growth means the growth of a sector in which income distribution is extremely polarized. One argument connecting the tertiary and inequality would, then, be based on income distribution within the tertiary itself.

There is another way in which the growth of the tertiary may contribute to inequality. The larger the mass of poorly paid, underemployed workers in the tertiary sector, the weaker the bargaining position of those workers who have been fortunate enough to secure jobs in the secondary sector. A poor, unemployed, rural population also provides a "reserve army of labor," but not one that is as readily available as that group, or population, which is employed at the bottom of the tertiary sector. Since tertiary workers are not likely to take jobs away from skilled industrial workers, the principal effect of their presence will be on the bargaining power of unskilled and semiskilled secondary workers. If the bargaining power of the lower ranks of secondary workers deteriorates, then we would expect increased inequality within the secondary sector.

Overall, we postulate that rapid growth of the tertiary is associated with a pattern of development in which the fruits of industrial growth and increased productivity accrue only to a restricted segment of the labor force, resulting in higher levels of inequality among those nations that have been more successful at "dependent development" (see Evans, 1979). This pattern of growth is what Taylor and Bacha (1976:198) refer to as the "unequalizing spiral" in which growth creates a "twist in the Lorenz curve with the poor receiving a smaller (and the rich a larger) share of the proceeds. . . ." In contrast to more optimistic models (e.g., Fei and Ranis, 1964), we agree with Taylor and Bacha (1976:216) that once dependent development has been institutionalized "there seem to be few ways to slow down or reverse the concentration process."

Our argument is not just that investment dependence, inequality, and growth of the tertiary are all components of the "unequalizing spiral" of dependent development. We would like to go further and argue that growth of the tertiary is an important intervening mechanism which mediates the effect of investment dependence on inequality. That is to say, that if investment dependence did not result in rapid growth of the tertiary its effect on inequality would be significantly reduced. In order to show this, of course, we must be able to show not only that investment dependence, growth of the tertiary, and inequality are all interconnected but also that when investment dependence and growth of the tertiary are both included in a model predicting inequality, a significant portion of the effects of investment dependence are not direct, but indirect—via the growth of the tertiary.

The Proposed Analysis

While the relationship between inequality and external economic dependence appears to hold for all nations—even controlling for level of economic development (Chase-Dunn, 1975:727; Rubinson, 1976)—*our* interest is in the developing countries. We are concerned with the ways in which foreign capital *shapes* economic growth. A heavy influx of foreign capital into an economy which was already industrialized should not have the same effects as those which we are postulating.

Our aim, then, is to test a rudimentary version of the line of reasoning which we have laid out. The test results can be only approximate, as we must rely on rather crude indicators of some of our key concepts.

First, we will attempt to replicate the previously discovered relation between foreign investment and inequality, hypothesizing:

(1) The greater the amount of foreign capital located in a given less-developed country, the higher the level of income inequality that will characterize that country.

Next, we would like to examine the relation between foreign investment and relative growth of the tertiary sector, hypothesizing:

(2) The greater the amount of foreign capital located in a given less-developed country, the greater will be the growth of the proportion of the labor force employed in the tertiary sector.

Third, we will examine the relation between growth of the tertiary sector and inequality, hypothesizing:

(3) The greater the increase in the proportion of the labor force employed in the tertiary sector, the greater is the level of income inequality. Furthermore, these overall effects are likely to be the result of the negative impact of the growth of the tertiary on the income of the poor.

Finally, we will examine the combined effect of foreign investment and the growth of the tertiary on inequality, hypothesizing:

(4) When the growth of the tertiary and investment dependence are considered together, the effect of foreign investment on inequality will be reduced, suggesting that some of the effect of foreign investment on inequality is mediated through its effect on the growth of the tertiary.

The Data and Measurement

Dependency. Two measures of economic dependence are used. The first, which we call Investment Dependence I, is "debits on investment income." Chase-Dunn (1975) uses this measure, and he has made it available to us. This measure is taken from the International Monetary Fund *Balance of Payments Yearbook* (1950–1955).

> It reports all profits made by foreign direct investment in the "host" country (regardless of whether or not they are repatriated). The average debits on investment income are computed for the period from 1950 to 1955 . . . and divided by the population. This variable, due to its badly skewed distribution, is converted to a logarithmic scale to make it suitable for use in linear regression analysis. (Chase-Dunn, 1975:728)

Since Investment Dependence I is the product of both the stock of foreign capital and of the rate of return on that capital during the period in question, it is a "flow" measure of investment dependence.[1]

The second measure of economic dependence (Investment Dependence II) consists of the total amount of direct investments by Organisation for Economic Co-operation and Development (OECD) nations in less developed countries. It is taken from an OECD (1972:4) publication.

> This study presents, by host country . . . estimates of the stock of direct private in-

---

[1] While Chase-Dunn's measure does represent accumulated profits over the five-year period, 1950–1955, and is a stock measure in this sense (cf. Bornschier et al., 1978:661), it depends on the rate of profit during this period as well as on the amount of capital accumulated previous to the 1950 to 1955 period; it is, therefore, also a "flow" measure when contrasted to a *purely* stock measure (like our Investment Dependence II).

> vestment of D.A.C. countries in LDCs at the end of 1967. By the stock of foreign investment in this report is understood the net book value to the direct investor of affiliates (subsidiaries, branches and associates) in LDCs.

Like Investment Dependence I, this measure of investment dependence has been divided by host country population and converted to a logarithmic scale. Unlike Investment Dependence I, it is a purely stock measure, representing the long-term accumulation of foreign capital. One advantage of such a measure is that it is relatively stable over time so that measurements from 1967 can be considered good indicators of levels ten years earlier. This feature is important to our analysis, since we must use the measures from the mid-sixties as indicators of earlier levels in order to maximize our number of cases.

There may be some objection to the use of ratio variables such as these since it may be difficult to distinguish the effects of investments from the effects of population (cf. Bollen and Ward, 1979). Effects of the log of investments, controlling separately for the log of population, have been estimated elsewhere (Timberlake, 1979:142–85), with results essentially the same as those presented here. We decided, here, to use per capita measures as population size had usually shown no significant effect on any of the dependent variables and because it would not, therefore, have been useful to include in the path diagrams.

Inequality. Paukert (1973) was the source of income inequality data for most of the cases in our analysis. He presents data showing the percentage distribution of income by households into quintiles from the poorest 20% to the richest 20%, with the richest quintile being further disaggregated into the 81–95 percentile group and the top (richest) 5%. A Gini index computed on the basis of the distribution of income into these quintiles is also presented by Paukert. These data are supplemented with data presented by Jain (1975), thus allowing us to increase the number of cases in the analysis. Of the data Jain presents, we use *only* the results of income surveys of national samples of households or income recipients. The fact that measures of relative size of tertiary labor force are available for two time periods will allow us to make causal inferences from our regression analysis when this is the dependent variable. However, our ultimate concern is understanding variation in levels of income inequality across Third World countries, and inequality data are available only for around 1960 for any significant number of countries. Analyses involving inequality as a dependent variable are therefore cross-sectional and, at best, only suggestive of possible causal ordering.

The tertiary sector. Labor force data have been prepared by Moir (1975; 1976) and made available to us. She has collected data on the distribution of the labor force into economic sectors for many countries for around three time periods: 1950, 1960, and 1970. These data were collected and grouped in accordance with a scheme which classifies as part of the tertiary the following groups of industries: wholesale trade and other nonretail commerce; retail trade; transport; storage and communications; government; armed forces; educational services; health services; other community, business and recreation services; domestic services; and restaurants and other personal services (Moir, 1975:60–2).

These data are grouped in such a way that it is impossible to isolate and measure that part of the tertiary that is "superfluous," even if that were, in principle, possible to determine. We have therefore contented ourselves with using the percentage of the labor force in the whole tertiary, and a measure of change over time in that percentage. We became somewhat less concerned with this shortcoming by discovering that the simple correlation is relatively high (.82) between the percentage in the total tertiary and the percentage in what might be termed the "traditional" tertiary (domestic service, and restaurants and other personal services) among the small number of countries (9) for which the latter measure is available in 1960.

Moir's data for around 1950 and around 1960 are used in the regression analysis. In regression equations in which change in the relative size of the tertiary is to be explained, we use the percentage of the labor force employed in the tertiary industrial groups in 1960 as the dependent variable, with the 1950 measure included as an independent control variable. This allows us to estimate the effects of the other independent variables on the relative size of the tertiary labor force in 1960 independently of its size in 1950. That is, we are estimating effects on *change* in the percentage of the labor force in the tertiary from 1950 to 1960. This method of explaining change has been suggested by Heise (1970) as a method of causal analysis which avoids the pitfalls of using change scores as dependent variables in regression analysis (also see Lord, 1956 and 1958; Bohrnstedt, 1969). Since the actual year in which the labor force data were recorded varies somewhat among the countries, we have also included in these equations the actual number of years that separate the "1950" measure from the "1960" measure. In this way we control for the fact that some tertiary sectors have been given more time to change than others.

We use a measure of change in the tertiary in order to estimate the effects of tertiary growth on levels of inequality. Again, inclusion of early and late measures of the relative size of the tertiary in the regression equation is a method of measuring the effects of change in that variable which is preferable to the use of a simple difference score, since the latter does not fully control for the effects of the initial level of the variable that is changing. However, when this was attempted in estimating the effects of change in the tertiary on inequality, the early and late measures of tertiary employment proved to be too highly intercorrelated to allow meaningful interpretation of the parameter estimates. Instead, we created a change score by computing the difference between the measure of the proportion employed in the tertiary in 1960 and an estimated proportion employed in 1960. The predicted score was computed on the basis of the least squares estimate from the following equation:

$$\hat{Y} = a + b_1X_1 + e \quad (1)$$

where a = constant

e = error

X_1 = proportion of the labor force employed in the tertiary, 1950

$\hat{Y}$ = estimated proportion employed in the tertiary in 1960.

The difference in $\hat{Y} - Y$ is the measure of change in tertiary employment used in the parts of the analysis in which income inequality is the dependent variable and change in the tertiary is one of the independent variables. It is also used in the path analysis. It represents that part of tertiary employment in 1960 that cannot be attributed to the level of tertiary employment in 1950. Since this residualized measure is, by definition, statistically independent of the early measure of tertiary employment, it is superior to the measure of difference between actual 1960 and actual 1950 tertiary employment.

Level of economic development. Per capita domestic product is included in regression equations in order to control for the possible effects of differences in the level of economic development within our sample of nations. The GDP estimates of Hagen and Hawrylyshyn (1969) are used. We use a 1960 measure, rather than an earlier one, in order to avoid further reducing the number of cases included in the tables. This should not be problematic since such indicators of development level are very highly correlated over time.

The cases. Since our concern is with the effects of foreign investment on industrializing nations, we eliminated all those nations with per capita incomes higher than $950 in 1965. Japan was also excluded. The effect of using a strict income criteria was to exclude most of the OPEC countries and include some of the poorer countries of Western Europe. In addition, lack of data eliminated a number of nations which would have otherwise been included. The "sample" consists of 56 poor countries. Among these 56 countries, very few have data on every one of our variables. In order to allow the broadest possible test of each of our hypotheses, we have included in each table all countries in the sample for which data were available for the variables under consideration in that table. The number of cases ranges between 49 and 18, except that the parameters of the path diagrams are estimated for two sets of "common cases" with 18 and 21 countries, respectively (see Appendix C and Appendix D). The total sample, and the cases used in each table, are shown in Appendix A.

Analysis of Results

The positive relation between investment dependence and inequality in poor countries is thoroughly reconfirmed in Tables 1a and 1b. In 1a we have used Chase-Dunn's measure of dependence and shown that in our sample both the strength of the effect of investment dependence on inequality and the statistical significance of the relation are even greater than they were in Chase-Dunn's original sample (cf. Chase-Dunn, 1975:734). Investment dependence is not only significantly related to the overall Gini index. It also has strong negative effects on the income shares of all three of the lower quintiles and a strong positive effect on the income of the top 5% of the population.

Using our other measure of investment dependence enables us to replicate these findings with a larger number of cases. Since this other measure of investment dependence is simply a measure of the amount of capital invested in a given less developed country and does not depend on the rate of profits obtained in that country, Investment Dependence II provides a good check on the possibility that the relation discovered by Chase-Dunn was due to effects associated with differential rates of profit rather than those associated with different total amounts of foreign investment. Tables 1a and 1b indicate that whether one uses a "flow" measure like Chase-Dunn's or a "stock" measure like Investment Dependence II, foreign investment is associated with inequality. The relation between Investment Dependence II and the Gini index is strong and significant, as are the negative effects on the incomes of the lower 80% of the population and the positive effects on the upper 5%.

These findings indicate that when foreign investment is relatively great in LDCs, then overall income inequality is also relatively great. Furthermore, these statistical effects on overall inequality appear to result from both a negative relationship of investment dependence with the relative amount of income held by the less well-off and its positive relationship with the proportion of income accruing to the rich. The data used here are cross-sectional, thus disallowing causal inference, but they are consistent with the theoretical argument that, in Third World countries, dependence on the capitalist core helps keep the poor impoverished while the rich get richer.

Impressed by these findings but remaining skeptical, we tried to explore the possibility that the relation might be spurious by introducing various additional variables into the equation. We thought, for example, that introducing population growth into the equation might diminish the relation between dependence and inequality. The relation held up well in the face of our experiments. For example, when population growth rate 1950–1960 was included in the regression equation that produced the results shown in Table 1a, the Beta associated with it was small (.013) and did not approach statistical significance. Furthermore, the estimated effect of Investment Dependence I was not reduced in either substantive or statistical significance (Beta = .671). We must conclude that, in the absence of strong future findings to the contrary, reliance on foreign investment must be considered to have negative statistical effects on equality in poor countries.

Next, we examine the effects of dependence on foreign capital on the change in relative size of the tertiary sector of the labor force. As Tables 2a and 2b show, both our measures of investment dependence have significant positive effects on growth of the tertiary. The more a poor country was dependent on foreign capital, the more rapidly the proportion of the labor force in its tertiary sector was likely to expand between 1950 and 1960.

The same is not true of the labor force in the secondary sector. When the same procedures used to test the relation between

investment dependence and the growth of the tertiary were repeated for the secondary sector, neither measure showed a significant positive relation. The relation was negative and almost significant in one case and insignificant in the other. The findings were, in short, what would be expected from our theoretical discussion of the effects of foreign capital. Foreign capital may draw a poor country's population into the market economy and into the nonagricultural labor force, but it does not appear to play a significant role in the expansion of employment opportunities in the secondary sector.

Turning to the relation between labor force structure and inequality, we found that only change in the tertiary—and not its size relative to other sectors of the labor force at any given point in time—was related to inequality. We examined the relation between various cross-sectional measures of labor force structure and inequality and, while there were a number of suggestive findings, none of them was sufficiently robust to merit real confidence. We did, however, discover a strong and consistent relation between the growth of the tertiary and level of inequality.

Those poor countries in which the tertiary had grown unusually rapidly between 1950 and 1960 had higher levels of inequality than those poor countries whose tertiaries had grown less. These results are shown in Table 3. Table 3 indicates that the growth of the tertiary has strong and statistically significant effects on overall levels of inequality, and its most powerful effects are on the income shares of the bottom 40% of the population.

It is important to emphasize at this point that what we have found is not simply a relationship between the growth of the nonagricultural labor force and of inequality. Obviously, the growth of the tertiary goes together with a decline of the proportion of the labor force in agriculture. But it is not the movement of labor out of agriculture, in itself, that is related to growing inequality. What is important is that this labor must be absorbed into the tertiary rather than into the secondary sector. We have already shown that there

is no association between the growth of the secondary sector and higher levels of inequality. It is true that a shrinking primary sector is associated with a smaller income share for the poorest quintile. But when we included both change in the tertiary and level of primary employment (in the equation predicting the Gini index and share of the poorest quintile), the effects of level of primary employment were reduced to statistical insignificance.[2]

One other alternative hypothesis should also be rejected. Since the results shown in Table 3 are essentially cross-sectional, it might be argued that the relationship we have found exists because relatively rapidly growing tertiary sectors are the result of income inequality. Ideally, we would need inequality data as well as tertiary data for two points in time in order to determine the direction of causation in the relationship between the tertiary and inequality, but we have inequality data for only around 1960. However, since we have measures of the relative size of the tertiary for 1970 (as well as for 1960), we can estimate the effects of income inequality in 1960 on change in the tertiary from 1960 to 1970. When we did this, we found that level of inequality in 1960 had no significant effects on growth of the tertiary from 1960 to 1970 (Beta = −.077). Thus, it seems reasonable to view, tentatively, the relationship between inequality and growth of the tertiary as being the result of the impact of the tertiary on the income distribution, rather than vice versa.

The final step in our analysis was to reexamine the relation between investment dependence and inequality, introducing the growth of the tertiary as an additional variable in the regression equa-

[2] The addition of a measure of change in primary employment into the equation that produced the results showing the effects of tertiary change on the Gini index and income share of the poorest quintile (Table 3) reduced the magnitudes of the tertiary effects slightly (Beta = .506, F = 3.35, and Beta = −.612, F = 5.50, respectively). However, the effects of change in primary employment were rather small and statistically insignificant (Beta = −.205, F = .59, and Beta = .107, F = .18, respectively).

tion. A range of results from this addition would be consistent with our theoretical model. Growth of the tertiary was considered to be an intervening variable and, therefore, more causally proximate to inequality. But we also assumed that other mechanisms, such as those discussed by Chase-Dunn and Rubinson, would operate and might, for some countries, be more important than effects which operated through labor force structure. Thus, investment dependence might continue to have a strong relation with inequality even when the growth of the tertiary was included in the regression equation, insofar as this relation represented effects mediated through other mechanisms. If the effects of investment dependence were reduced to insignificance, it would suggest that, at least for the sample used, growth of the tertiary was the principal intervening variable connecting investment dependence and inequality. Only if the growth of the tertiary ceased to have any effect on inequality once investment dependence was introduced into the equation, would the results have been inconsistent with our theoretical model.

The actual results, shown in Tables 4a and 4b, are quite favorable to our hypothesis. In both tables, the growth of the tertiary continues to have (substantively) rather strong effects on the Gini index, even with investment dependence included in the equation. The effects of change in the tertiary on income accruing to the poorest quintile are negative, as predicted, and moderately strong, but its effects are statistically significant only in the equation with Investment Dependence II (Table 4b). If we restrict our attention to the effects on the overall index of inequality and the income share of the poorest quintile, it is important to note that the effects of the investment-dependence variables were reduced to statistical insignificance, in each case. The magnitudes of the effects of the investment dependence variables are, likewise, dramatically reduced—compared with those estimated for the subsets of 18 and 21 cases common to Tables 4a and 4b, respectively (see Appendix C). These findings indicate that growth of the tertiary does mediate some of the previously

disclosed effects of investment dependence.

A somewhat more elegant way of illustrating the same argument with these findings is to use path diagrams to display the results of the common case analyses. We have done this, focusing on the Gini index of income inequality. Our fourth hypothesis suggests that change in the tertiary mediates some of the effects of dependency. To test this argument, we need to decompose the total effect of dependency on income inequality. Path analytic techniques provide a way to state this total effect in such a way that the direct and indirect effects can be distinguished.[3]

Figures 1a and 1b, one for each of the two dependency measures, represent path diagrams of the model we are suggesting. The indirect effect of Investment Dependence I on the Gini index through the growing tertiary ($p_{43}p_{31} = .457$) is more than four times greater than the direct effect of this measure of dependency ($p_{41} = .106$). As the direct effect is the only other positive coefficient, one could argue that more than 80% of the positive direct and indirect effects of Investment Dependence I on the Gini index operate through its effects on the bloating tertiary. The results obtained when we compute the direct and indirect effects of Investment Dependence II on the measure of income inequality from Figure 1b are not as dramatic, but they also support the hypothesis that the exacerbating effects of dependence on levels of inequality are mediated by the effects of investment on the tertiary. In this case the mediated effects ($p_{43}p_{31} = .4425$) are somewhat smaller than the direct effects of Investment Dependence II ($p_{41} = .5440$) and they account for about 45% of the total positive direct and indirect effects of dependency ($p_{43}p_{31} + p_{41} = .9865$) on the Gini index. The results shown in the two path diagrams and discussed here provide rather strong support for viewing the growth of the tertiary as an important way in which dependence adversely affects the income distribution.

Discussion

The findings presented here must be considered strong empirical reinforcement for the idea that reliance on foreign capital is likely to contribute to the inequality of the distribution of incomes in poor countries. We have not only replicated Chase-Dunn's and Rubinson's results

---

[3] A discussion of the way in which the path coefficients were estimated can be found in Appendix D.

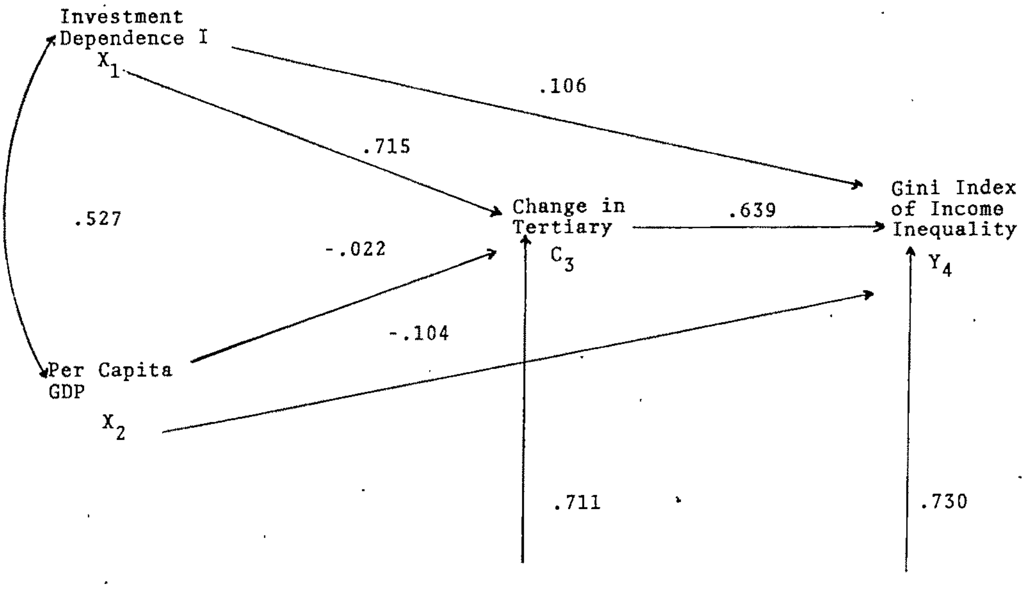

Figure 1a. Path Diagram of Final Model with Investment Dependence I

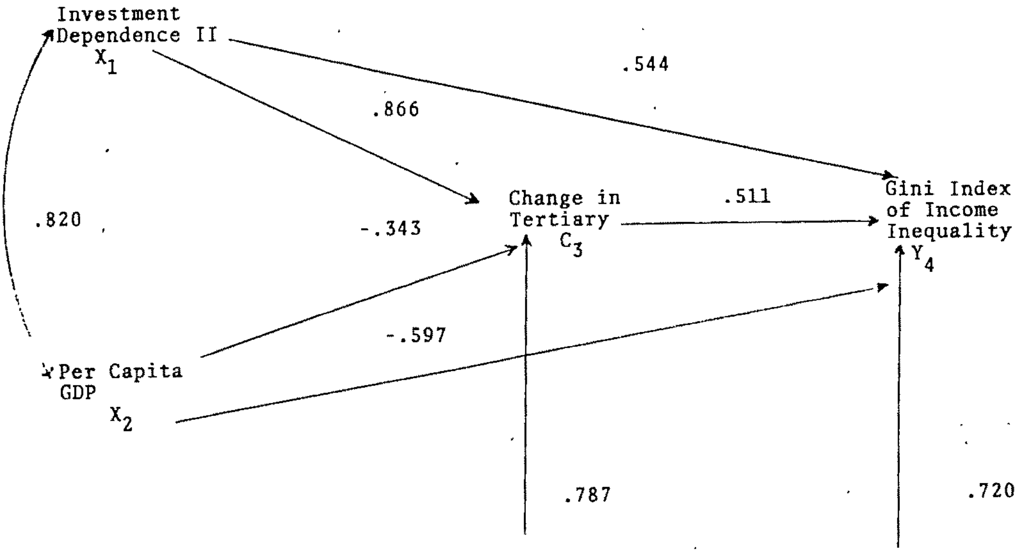

Figure 1b. Path Diagram of Final Model with Investment Dependence II

with additional inequality data and confirmed them, but also tested the hypothesis using a conceptually different measure of investment dependence. While Chase-Dunn's measure of dependence is a "flow" measure—that is, one which indicates the flow of profits from foreign-owned investors during a given period—our second measure of investment is a "stock" measure. That is, it indicates the total stock of foreign investment which has been accumulated in a given country, over time. The fact that the relation between investment dependence and inequality can be confirmed for both flow and stock measures makes the findings all the more convincing.

The credibility of the relation has also been increased because we were able to test it across a broader sample of poor countries than in any previous investigation. Using our second measure of dependency, we were able to include almost 50 less-developed countries in our sample. Given our findings, it is very difficult to argue that the relation between investment dependence and inequality is due to the peculiarities of a restricted subset of Third World countries. It may still be the case that foreign capital is associated with inequality only during a specific historical period. But it seems safe to say that, at least during the sixties, high levels of external economic dependence went along with high levels of inequality throughout the Third World.

We found a fairly strong, positive relation between the growth of the tertiary and our measures of inequality and a clear relation between reliance on foreign capital and the growth of the tertiary sector. Our data also support the idea that the growth of the tertiary can be considered one of the mechanisms through which reliance on foreign capital is related to higher levels of inequality.

Furthermore, we have found that growth of the employment in the secondary sector is not related to higher levels of inequality and that high levels of dependence on foreign investment are not associated with rapid growth of employment in the secondary sector. In short, dependence is not associated with inequality simply because dependence is associated with the growth of the modern sector; the relation between dependence and inequality is a function of the *kind* of modern sector that is created.

The findings presented here have several implications for students of inequality in developing countries. For those trying to elucidate the relation between investment dependence and inequality, our results reinforce the idea that foreign investment exacerbates inequality not because it prevents capitalist accumulation in the Third World but because the capitalist accumulation it fosters is so strongly exclusionary and inegalitarian. For those who are interested primarily in labor force structure, the main contribution of our findings is to suggest that variables not often considered in such studies, like investment dependence, may be of significant help in explaining differences in labor force structure among countries at similar levels of development. It would be most interesting, for example, to discover whether other kinds of dependence, like trade dependence and aid dependence, have similar consequences for the growth of the tertiary.

More immediately, the empirical confirmation of the connection between foreign investment and the growth of the tertiary makes essential further exploration of the reasons for this connection. So far, it has been assumed that foreign investors may influence the shape of the labor force by choosing different technologies of production than local capitalists would. Other kinds of influence deserve more attention. Nontechnological effects of penetration by foreign capital on the labor-absorbing capacity of the agrarian sector deserve further attention. So does the hypothesized tendency of the multinational to exacerbate the "city lights effect."

For those interested in policy rather than in further research, the results do not offer too much in the way of positive suggestions, but may provide some useful suggestive information. On the one hand, they supply yet another piece of evidence against the assumption that the growth of the modern sector will diminish inequality. On the other hand, they suggest that reducing investment dependence will have an impact on inequality only if the social structural consequences of past dependence are also dealt with. If we are correct in assuming that most of the influence of investment dependence is mediated through changes in underlying social structure, the resultant inequality will persist long after the last subsidiary is nationalized. But this is, of course, what the elevator operator has suspected all along.

APPENDIX C

THE COMMON CASES ANALYSIS

The results shown in Tables 1a–4b are based on the maximum possible number of cases. Since data on some variables are missing for some countries, this leads to differences in the cases included in the tables, depending on the variables involved. Inferences made on the basis of comparisons between or among tables can be questioned because differences or similarities may be the result of switching cases rather than due to "real" differences. We have therefore replicated these results on two sets of "common cases." One set consists of the 18 cases for which we have measures of Investment Dependence I, proportion of the labor force in the tertiary in 1950 and 1960, per capita GDP, and inequality. The other set of cases consists of the 21 countries with measures of Investment Dependence II, and the other 4

Table C1. Standardized Regression Coefficients from Tables 1a–3 and from "Common Cases" Analyses

variables. Table 4a is already based on the first of these sets of cases, and Table 4b is based on the second set. The results in Tables 1a–2b have been reestimated for the appropriate set of common cases, depending upon which of the two investment dependence measures was used. Table 3 has been reestimated for both sets of common cases. Table C1 summarizes these results by presenting the standardized regression coefficients (Betas) from the common cases analysis in comparison to the corresponding Betas from the "maximum cases" analysis (Tables 1a–3). Both measures of investment dependence have fairly strong, positive, and statistically significant effects on the Gini index of income inequality in the replications of Tables 1a and 1b. Both investment dependence measures continue to have moderately strong and statistically significant positive effects on growth of the tertiary, and growth of the tertiary continues to have significant positive effects on the Gini index in both sets of cases. In short, the results obtained earlier are very similar to the results obtained when attention is restricted to sets of common cases. Tables C2 and C3 present correlations among the variables in the analysis for the two sets of common cases.

Table C3. Correlation Matrix of Variables in Analysis Using Cases Common with Table 4b (n = 21)

	1	2	3	4	5	6	7	8
1. % in Tertiary 1950	1.000	.911*	.000	−.245	.795*	−.231	−.054	.550*

ERRATA

■ Three errors unfortunately occurred in "Synthesis and Comparison of Stratification Theories: A Reply" (to Attewell and Fitzgerald's Comment on an earlier article) by Robert V. Robinson and Jonathan Kelley in the April, 1980, *ASR*.

On page 328, column two, last paragraph, a type-correction line for the previous paragraph was, incorrectly, inserted as the second line of the first sentence. The second line should have read "zation of control, we defined the capitalist". The entire correct sentence—Employing this definition and operationalization of control, we defined the capitalist class as those who control the means of production and exercise authority (that is, have employees or subordinates) and the petite bourgeoisie as those who control the means of production but do not exercise authority.—was critical to Robinson and Kelley's reply, toward explaining their position and toward understanding the remainder of the article.

On page 329, Table 1, second column, the "Control (1)" figure—.184—for "Dahrendorf: Authority" should have read: .184*—the asterisk indicating that it, too, was significant at the .05 level.

On page 332, Table 3, the third-column figure—.115—for "Marx: Control (cols. 1 and 2) or Ownership (cols. 3 and 4)" should have read .115*—the asterisk indicating that it is significant at $p < .05$. Because of the omission of the asterisk, Attewell and Fitzgerald's claim (that [Robinson and Kelley] slighted the Marxian model by employing a job earnings measure) seems to be more substantiated than it, in fact, is.

BANKS AND CORPORATE LENDING: AN ANALYSIS OF THE IMPACT OF THE INTERNAL STRUCTURE OF THE CAPITALIST CLASS ON THE LENDING BEHAVIOR OF BANKS*

RICHARD E. RATCLIFF
Syracuse University

American Sociological Review 1980, Vol. 45 (August):553–570

This paper analyzes the lending patterns of commercial banks in a major metropolitan area. The banks are studied in terms of their ties, through the members of their boards of directors, to networks of economic power and upper class social interaction within the metropolitan structure of the capitalist class. The central research question concerns whether the extent of a bank's centrality to these networks substantially influences the decisions made by each bank regarding the allocation of the capital it commands. While attempting to consider the broader social consequences of private economic power, the paper addresses three problems found in many recent studies of interlocking directorates: the general lack of attention paid to questions of social consequences as opposed to issues of structure; conceptual confusions central to explanations that focus on notions of "cooptation"; and the omission of measures on the dimension of economic power. The empirical analysis, dealing with the impact of class structure, economic power and institutional size measures upon the distribution of bank loan capital, reveals that the main determinants of lending are the class structure characteristics of banks as these are reflected in the network linkages of their boards of directors. In particular, banks whose directors are tied to numerous local corporations which represent major concentrations of economic power and, to a lesser extent, to the most exclusive upper class social circles are those most likely to emphasize concentrated lending to capitalist borrowers and, correspondingly, most likely to withhold capital from mortgage loans. It is also shown that these differences in lending behavior are not related to the profitability of the banks themselves. It is argued that these patterns are best explained by a model of capitalist class coordination in which dominant groups exercise their abilities to influence banks and corporations in ways that benefit their interests. These findings are examined in terms of the general economic stagnation and even decline of older urban areas.

In recent years we have witnessed an impressive proliferation of studies of networks of interlocking corporate directorates (Allen, 1974; 1976; Levine, 1972; 1977; Sonquist and Koenig, 1975; Bearden et al., 1975; Bunting and Liu, 1977; Warner and Unwalla, 1967; Mariolis, 1975; 1977; Mintz and Schwartz, 1977; Smith and Desfosses, 1972; Pennings, 1978; Bonacich and Domhoff, 1977; Stanworth and Giddens, 1975). While the present study also examines such networks, it differs substantially from most of the previous work. It focuses not just on the structure of private economic power, but, more importantly, on the consequences of the exercise of that power. Thus, in looking at the flow of capital in a metropolitan area, this study is most concerned with joining the question of "Who holds positions of power?" with the question of "So what?" In particular, the analysis examines the ties that commercial banks in St. Louis, Missouri have to networks of economic power and upper class social interaction within the metropolitan structure of the capitalist class and, then, considers whether a bank's centrality to these networks substantially influences the lending decisions made by each bank regarding the allocation of the capital it commands.

Critical Issues in the Study of Interlocking Directorates

This paper addresses three major problems which exist in many recent studies of interlocking directorates and related social network. These problems are: first, the general lack of attention to

questions of effects, outputs, and significant social consequences associated with differing structures of organizational interlocks and social networks; second, a vagueness of the dominant theoretical orientations concerning the issue of what motivates the establishment of interconnections among corporations and how these interconnections relate to larger structures of power; and third, the typical omission of measurable indices of economic and social power and importance other than those defined by the dimensions of "interconnectedness" used to identify network patterns. Each of these problems merits some discussion.

a. Interlocking directorates and social consequences. Most recent studies of interlocking corporate directorates have been limited to considering the structural patterns represented by the interlocks. There have been inquiries regarding whether corporations are formed in interest group clusters (Allen, 1978; Sonquist and Koenig, 1975); whether the positional centrality of banks indicates patterns of bank dominance in interlock relationships (Mariolis, 1975); and whether the interlock patterns suggest efforts by firms to establish supportive and cooptive relationships with other firms of importance to their operations (Allen, 1974; Burt, 1978a; 1978b). While these studies raise important issues, what is largely missing is any attempt to demonstrate whether interlock patterns, and more specifically the structures of private economic power embodied in such patterns, lead to consequences of substantial importance for the larger society.

This lack of any attention to questions of the consequences of private economic power parallels a similar trend in the extended debates concerning community power (Aiken and Mott, 1970). These debates, which originally stimulated much of the research on interlocking directorates discussed here, not only have tended to become overly focused on questions of structure, but also have increasingly dealt less with private economic power. Growing out of the unresolved disputes over "structures," there have been some attempts in the community power literature to look at outputs. Most of these attempts, however, have been focused on the public realm, such as considering how organizational factors influence a range of outputs including the level of public spending for various programs, the success of different communities in obtaining federal grant-in-aid funds, the policy decisions regarding school integration, and the imposition of water fluoridation (Clark, 1975). There have been few studies concerning outputs associated with private decisions, such as those made by major corporations and banks and their owners and managers. Most of those that do exist have been largely centered around case studies that emphasize qualitative rather than quantitative analyses (Hayes, 1972; Hartman, 1974).

This lack of attention to consequences is especially striking because studies of interlocking corporate directorships, as well as those of community power structures, were originally motivated by theoretical and substantive questions that certainly were grounded in concerns over the social implications of private economic power. For example, Louis Brandeis, writing in 1913 in reaction to an early legislative study of corporate concentration, saw corporate interlocks as "the root of many evils," including the suppression of competition and the centralization of economic power that represented a major threat to a democratic society (Brandeis, 1913:13). C. Wright Mills saw interlocking directorates as representing a level of coordination which is tied less to "any specific property interest" than it is to "class-wide property" and that embodies "the community of interest," and "the unification of output on policy, that prevails among the propertied class" (Mills, 1956:122–3). A more recent government report suggested that interlocking directorates could

> . . . lead to a concentration of economic and fiscal control in a few hands. There is in this the danger of a business elite, an ingrown group, impervious to outside forces, intolerant of dissent, and protective of the status quo, charting the direction of production and investment. . . . (U.S. Senate Committee on Governmental Affairs, 1978:6)

Even more generally, the concern with interlocking directorates has been linked with questions of whether large corporations, given the increasing concentration among corporations in recent decades, have emerged as the dominant centers of power within the society (Useem, 1978; 1979).

While the declarations by Mills and others concerning the social importance of consequences that might flow from corporate interlocks have not stimulated much recent research on the question, among those studying such interlocks there have been some limited exceptions. One area of corporate behavior where there has been attention to outputs concerns corporate profit rates (Gogel, 1977; Burt, 1978a; Norich, 1980). The study of profit rates as an output in studies of corporate structure does have some justification. Profit rates are relevant to an understanding of the ability and success of firms in seeking to maximize their own interests and to achieve greater firm efficiency. In addition, critics of the "managerial thesis" have identified profit rates as a reasonable standard for evaluating the supposed distinctions between corporations of different ownership types (Norich, 1980). More generally, profit rates also provide a standard for examining the ability of firms and groups of firms to accumulate concentrations of capital.

Despite the relevance of profit rates for some questions, corporate profits are not clearly related to the theoretical and substantive problems concerning the societal effects of private economic power that originally motivated most studies in this area. Researchers studying profit rates as outputs have generally not shown what importance the differences in profit rates of firms have for understanding questions that reach beyond the issue of corporate interconnections. While profit rates do have the advantage of being measurable, using available data, this advantage does not override their fundamental limitations.

This study does focus on consequences. The analysis presented here examines the lending behavior of banks, an area of economic behavior that clearly does have broad social implications especially in studies of contemporary urban problems. Banks have a unique character as private enterprises: they have the function of accumulating surplus capital from depositors throughout their communities and then making investment decisions on how this accumulated capital is to be allocated in the form of loans. Patterns of loan decisions can be assumed to represent policy priorities established by the officers of the bank and by its board of directors (Reed et al., 1976:149). In their loan decisions, banks are, in effect, deciding on how a substantial portion of the surplus capital, accumulated from the entire community and owned by a diverse range of depositors in the community, is to be distributed. While a broad range of demands exists for that capital from prospective borrowers, banks are able to determine which demands are met. As a result, they routinely influence "the allocation of real resources" in the society and, in effect, "what is produced, how it is produced, and to whom it is distributed" (Harvey, 1975:125). This quasi-public character of banks, despite their status as private, profit-seeking enterprises, has been long recognized in this country. Brandeis, writing over a half century ago, stated that because "bank resources are, in the main, not owned by the stockholders nor by the directors," and because the "dependence of commerce and industry upon bank deposits as the common reservoirs of quick capital is so complete . . . deposit banking should be recognized as one of the businesses 'affected with a public interest' " (Brandeis, 1913:15). Similarly, a modern textbook on banking states, "The major reason banks are chartered is to serve the credit needs of their communities. If this cannot be done, there is little justification for their existence" (Reed et al., 1976:150). Government regulation of banking has also reflected the understood obligation of banks to meet community credit needs (U.S. Senate Committee on Banking, 1977).

Bank lending decisions are of particular importance in areas such as St. Louis, which not only face a diverse range of internally based demands for capital, but which also are called upon to provide capital for investments in more rapidly growing sections of the country (Ratcliff, 1980a; 1980b). The resulting loan distributions of banks are thus related to issues of disinvestment within the metropolitan area, and especially to such critical questions as the availability of capital for investments in local housing, and to the processes of stagnation, disinvestment, and decline in older metropolitan areas (Bradford and Morino, 1977).

b. Ambiguities in theories of interorganizational relationships. Recent treatments of interlocking directorates have not clearly specified what motivates the establishment of interlocks. The most general theoretical approach offered to explain interlocking corporate directorships has centered around the notion of "cooptation." For example, Allen has suggested a "theory of interorganizational elite cooptation" which sees interlocking directorates as representing "an attempt by corporations to anticipate environmental contingencies and to control their relationships with other corporations" (Allen, 1974:393). He notes further that such interlocks constitute "a cooperative strategy anticipating or controlling potentially disruptive unilateral actions by other organizations" (Allen, 1974:403). Within such a framework, interlocks between banks and corporations are seen as quite rational cooptive arrangements. Thompson suggests that corporations seek bank interlocks in order to increase "their access to financial resources for the duration of the cooptive arrangement" (Thompson, 1967:35).

While this perspective is generally plausible, it suffers from being both vague and potentially tautological. The statement of a cooptive motivation becomes of little use in evaluating theories of power and control over corporations if it simply means that firms, like people, tend to act in their own self-interest in ways that allow them to experience gains or control losses. In the context of proposing a solution, one proponent of the cooptation approach acknowledges this problem when he states that discussions of "interlocking directorates as cooptive devices do not advance theoretical understanding of corporate interlocking as much as provide a sociological label for it" (Burt, 1978a:2; 1978b).

An additional unresolved problem in this cooptation theoretical approach is that the model assumes a basically atomized organizational set in which individual organizations are analyzed in terms of whether they have chosen either to be or not to be linked with other organizations. The factors motivating such choices are assumed to be tied to the problems and prospects experienced by individual corporations. Thompson, for example, argues that cooptation as a strategy is most likely to be pursued by organizations in a weakened position seeking to "avert threats to their stability or existence" (Thompson, 1967:35). Organizations are thus seen as individualized decision-making units that are drawn into relationships of dependency, thus losing their autonomy in order to reduce uncertainty. Such an individualized approach does not appear to do justice to the problem. In particular, the "cooptation theory" perspective fails to account for any structures of power and control that are not firmly based in any one organization. This limitation is unfortunate since one of the motivating concerns in the whole area of social networks has been that the relevant units of organizational control and coordination might be larger structural configurations.

The present paper builds upon a model of capitalist class coordination. The concern here is with the extent to which interconnected and coordinated groups within the capitalist class are able to exert power and control over sets of firms in a way that is advantageous to the dominant groups involved in them. In such a system, it would not be necessary to assume that a dominant group is synonymous with any one organization in the network. Instead, power and control could be based in a group that simultaneously has interest in a number of organizations. Interlocking directorates can be seen as important manifestations of power relationships of the dominant groups.

This class coordination perspective draws upon analyses of "finance capitalists" and "interest groups" in that both corporations and banks are seen as being tied to more inclusive networks of power within the capitalist class (Sweezy, 1942:chap. 14; 1953). Rudolf Hilferding, whose 1910 book focused attention on finance capitalists, saw interlocking directorates as a crucial aspect of these networks, often indicating other less visible dimensions of interconnections such as ownership. Hilferding wrote about the "personal union" and "community of interests" embodied in ". . . a circle of persons who, thanks to their own possession of capital or as representatives of concentrated power over other people's capital (bank directors), sit upon the governing boards of a large number of corporations" (Hilferding [1910] cited in Sweezy, 1942:261). Imbedded in Hilferding's analysis were two conflicting views of the role of banks in their relationships with corporations. On the one hand, banks were seen as the organizers of the capitalist class, imposing order, discipline and some centralized planning on a potentially overcompetitive economic system in order to achieve some overall level of improved internal efficiency. On the other hand, banks were seen as centers of speculative and even predatory activity leading to corporations being raided and "run into the ground" by banks seeking their own profits. Even without resolving these views, Hilferding saw banks and finance capitalists as becoming increasingly dominant over corporations.

The research reported here is not based on any assumption that banks are the dominant forces in their relationships with corporations. While the special character of banks as holders and distributors of capital makes them likely centers of class organization and coordination, both banks and corporations are seen here as possibly interconnected points of decision making within larger networks of class interests. Rather than expecting any one bank or corporation to act as a centralized point of dominance, it is more useful to see an ongoing effort by groups within the capitalist class with lines to both banks and corporations attempting to maximize benefits in different forms at a number of separate points. A similar view has been suggested by Zeitlin:

> Neither "financiers" extracting interest at the expense of industrial profits nor "bankers" controlling corporations, but finance capitalists on the boards of the largest banks *and* corporations preside over banks' investments as creditors *and* shareholders organizing production, sales, and financing, and appropriating the profits of their integrated activities. (Zeitlin, 1976:900, emphasis in the original)

Thus, while the cooptation model sees corporations and banks as distinct islands of self-interest searching for strategic alliances, the class coordination model sees both banks and corporations as vehicles for the interests of groups able to dominate, or at least heavily influence, the actions of individual firms.

Despite the conceptual clarity in the contrast between the cooptation and the class coordination perspectives, it is difficult to frame an unambiguous test to determine which is more appropriate. One partial test is allowed by the focus on bank lending decisions. Patterns of lending decisions can be examined simultaneously in terms of the effects of structural characteristics of the banks and, most notably, of their size, and in terms of the effects of corporate and upper class organizational interlocks. In important ways, the cooptation perspective would suggest that bank behavior would follow individual structural characteristics, while the class coordination perspective would emphasize the influences of network linkages.

While this comparison is important, this study also presents an opportunity for a more fundamental test of the usefulness of the two contrasting perspectives. This test involves an analysis of bank profit rates. Even though the use of profit rates was criticized earlier as an output measure of the social impact of private economic power, profit rates are directly relevant to the issue of what forces motivate organizational behavior. The key issue here is whether banks appear to be acting as independent units, seeking to maximize the benefits they receive individually, or whether they are being motivated by some broader set of interests.

Given what some people have seen as the dominant role banks exercise over corporations in lending relationships (as is reflected in the power of banks to deny or approve loans), a perspective that emphasizes basic organizational autonomy would presumably also make certain assumptions about the distribution of bank profits. If, as the cooptation model assumes, firms seek interlocks in order to stabilize and improve their positions, then banks that are successful in establishing corporate interlocks should enjoy the highest rate of profit. Such a linkage between the achievement of strategic interlocks and the attainment of higher profits has been specifically predicted in one elaboration of the cooptation model (Burt, 1980). From this same perspective it is reasonable to expect that banks most involved in lending to corporate and other "blue-chip" borrowers would also experience higher rates of profits (Starr, 1975).

In contrast, according to the class coordination perspective, it is not necessary that banks with more interlocks will be more profitable. If larger class networks control both banks and corporations, it is not possible to say whether economic gains among interlocked banks and corporations would be realized as profits by either individual banks or corporations or in some other form by other firms in the same network. It is quite possible, since the interests of corporations are most served by ready access to low cost capital, that lending to corporations will not necessarily yield high profits for banks. Banks could be much more important to groups that control them as accumulators of available capital than as centers of profit. Thus, whereas the cooptation perspective would presumably predict a direct relationship between corporate lending and bank profitability, the class coordination thesis makes no such prediction.

c. Economic power and network interconnections. Studies of interlocking directorates, with their focus on relationships among organizations, have represented a critical perspective on more traditional organizational studies that have only examined more individualized or static dimensions of power. However, actual research accomplishments have lagged behind the image of an approach that seeks to integrate complex interrelationships of power. With the emergence of more sophisticated mathematical, computer-based and statistical techniques in studies of organizational interlocks, research has become increasingly limited in its ability to incorporate multiple dimensions of power. Thus, most studies of interlocks are concerned with only one dimension of interorganizational importance—that of the interconnections themselves (cf. Levine, 1972; Sonquist and Koenig, 1975). Regardless of their differing individual characteristics, all firms typically are treated as equal units and then analyzed in terms of whether they are more or less central, based on their patterns of interconnections.

The omission of dimensions directly relating to economic power is unfortunate because vast differences in size and in power are so characteristic of the corporate realm. In the present study, the goal is to characterize the interconnections between banks and corporations in terms of not only their intensity, but also the corporate power and potential capital demands that they represent. The former dimension is measured by the number of large corporations tied to a bank. In order to incorporate the dimension of corporate power, I have assumed that corporations can be compared according to their total number of employees.

There are several advantages in using the number of employees as a measure of corporate power, including the availability of data and the reasonable comparability of this measure across sectors of the economy. Ideally one would compare firms on their total assets. However, given the focus in this study on the entire population of corporations of some substantial size in one metropolitan area (many of which are not only not listed in the major stock exchanges but also do not even have their stock publicly traded), it became clear that it was not practical to attempt to gather asset information. Data on sales are available for most corporations, and could roughly be estimated for the rest, but sales data produce even more problems than number of employees in making comparisons across different sectors of the economy. For example, retail firms, public utilities, transportation firms, and nonbanking financial corporations have very different relationships of sales to actual firm sizes than do manufacturing firms. Further, manufacturing firms also differ greatly among themselves. The number of employees (information which generally is available) does give a reasonable approximation of the economic and social importance of each firm.

Having discussed the strategies employed in this paper in relation to the three problems existing with most studies of interlocking directorates, I shall now move to present the results of my own research. First, however, I shall present a more integrated statement of the theoretical approach I am pursuing.

Banks and the Command of Corporate Capital

The general thesis guiding this research follows the capitalist class coordination model. It holds that banks tend to operate not only as profit-seeking enterprises in their own right, but also as the capital-accumulating appendages of the groups and interests within the class to which they are most closely connected. It is argued that this dual character of banks becomes most relevant for those banks which are closely tied to dominant groups at the center of the class where there exists the concentration of both demands and opportunities for capital investments. Banks can be expected to loan the funds they command in ways that reflect their class structure positions (Ratcliff, 1980a; 1980b). The internal structure of the class can be divided along two dimensions of centrality: economic power and upper class social interaction. The dimension of economic power can be represented in terms of ties to the corporate structure while upper class social interaction is represented by ties to exclusive private upper class organizations (Ratcliff et al., 1979). While the association of the first dimension with greater capital demands is apparent, research has also shown how upper class social ties are important in integrating the sometimes divergent economic interests of leading capitalists (Domhoff, 1970; Baltzell, 1958). Banks more closely tied to centers of either economic power or upper class social interaction, and especially those tied to both, should concentrate their lending in the direction of capitalist borrowers similarly located in the class structure, with corporate loans in particular predominating. In contrast, banks more peripheral to the dominant groups within the class can be expected to be subject to a more diverse range of demands for capital, as well as a set of opportunities less concentrated in the corporate sphere, with the consequence that their loans will be less exclusively directed toward major capitalist borrowers. One result is that the more marginal banks should be substantially more involved in mortgage lending.

This thesis has found support in research recently completed (as part of this same project) on mortgage disinvestment by banks in the St. Louis area (Ratcliff, 1980a; 1980b). Looking at home mortgage loans made by banks during 1975 and 1976, considerable variation was found among banks, both in the extent of their involvement, relative to their sizes, in providing home mortgage loans, and in the extent to which they provided home loans in older low and moderate income neighborhoods within the metropolitan area. Evidence of disinvestment and withdrawal of capital from home mortgage lending in such neighborhoods was shown to be characteristic of those banks most closely tied to the centers of economic power and upper class social integration within the capitalist class.

The Research Data

This study focuses on all 78 commercial banks which in 1975 had their headquarters either in St. Louis City or St. Louis County, the two dominant counties in the St. Louis SMSA, and on the 890 directors of these banks. Missing information caused the deletion of one bank from the present analysis. "Loan portfolio" data for the last day of 1975 were obtained on each of the banks from the Federal Reserve System. These data come from the "Reports of Condition" that each commercial bank is required to file periodically with federal regulatory agencies. In these reports, banks must specify the total dollar amount of outstanding loans they have in each of over 20 categories.

In this analysis, two distinct types of loans are treated as "outputs." The first type consists of loans in categories where the borrowers appear to be either corporations, partnerships, or individual capitalists obtaining loans in order to make or maintain investments in profit-seeking activities outside of real estate. These "loans to capitalists" represent a combination of several different categories of loans: commercial and industrial loans; loans to U.S. commercial banks and other financial institutions; and loans given either to brokers or nonbrokers for the purchase of securities. The second type includes all conventional and government guaranteed mortgage loans on one to four unit residential properties (predominantly single family homes). Specific measures used are the percentages that each loan type is of all loans outstanding from each bank.

These data do have certain limitations. Most notably, it is not possible to identify the recipients, the sizes, or the geographic destination of individual loans. Thus the recipients of commercial and industrial loans could be either major or small corporations, and the loans could be used either locally or elsewhere. The lack of location information for the home mortgage data is less of a problem because a separate study has been made of that issue using geographically specific data made available under the Home Mortgage Disclosure Act (HMDA) (Ratcliff, 1980a; 1980b).[1]

In order to determine the economic "networks" within which each bank was situated, all interlocks between bank directors and the largest corporations in the St. Louis area were identified. Determining the list of St. Louis corporations and their directors was a complex task. The major published directories of corporations, such as the Dun and Bradstreet *Million Dollar Directory*, proved to be very incomplete on the metropolitan level. A number of other directories were consulted in order to identify the population of St. Louis corporations of comparable size to those in the *Million Dollar Directory* based on sales and/or number of employees. Through these processes, 350 St. Louis based corporations were identified which were still in business in 1976, and which were not subsidiaries of other corporations on the same list (some firms left in the study were subsidiaries of other, usually nonlocal, corporations that, nonetheless, maintained local boards of directors). Information on file with the Secretary of State of Missouri providing the names of the board of directors of each Missouri corporation was consulted in cases where the data were not provided in directories. The search yielded over 3,000 directorship positions. For each of the 350 St. Louis corporations, the total number of employees was ascertained.

With these data two measures of economic interconnections were calculated for each bank. The first measure is the total number of firms among the 350 to which the bank is directly linked through a shared director. The second measure is the total combined number of employees for all corporations with which each bank is linked. Neither of these measures is affected if a bank has more than one director link to any one corporation since the interlock and the total number of employees are each only included once.

The bank directors were also examined to determine which had been involved in any of five organizations found to be the most exclusive in upper class social circles in St. Louis (Ratcliff et al., 1979). These organizations consist of two men's clubs, one country club, the *St. Louis Social Register*, and the Veiled Prophet Society, a secret organization of St. Louis men which holds a highly exclusive debutante ball each year. Membership lists or directories were obtained for the first four organizations. For the Veiled Prophet Society, a search through newspaper archives was conducted in order to determine all bankers who had either had a daughter as a debutante or a wife as a "Lady of

---

[1] For mortgage analyses, the HMDA data have the advantage (in addition to geographic specificity) of reporting new loans for a specific year, thus being sensitive to recent policy priorities of a bank. Loan portfolio data, on the other hand, have the advantage of indicating the overall commitment of a bank to mortgage lending at a particular point in time. Even though mortgage loans are given for a long term, often up to twenty-five or thirty years, they also can be bought or sold on the secondary mortgage market. Therefore, a current year's loan decision might not represent the accumulated commitment of such loans for a particular bank.

Honor" in the Ball during any of the previous twenty years. Involvement in these organizations was found to be highly intercorrelated and distinct from other clubs and social organizations for which membership information was collected. The particular measure of the closeness of each bank to networks of "upper class social prominence" used here is the proportion of bank directors in each bank who are tied to at least one of the five exclusive social organizations. The great advantage of these data on exclusive social organizations is that they make possible the incorporation of the dimension of upper class networks in a manner that is conceptually and empirically distinct from the data on corporate or economic networks.

The size of the banks is measured by the total deposits of each on the last day of 1975. The holding company status of each bank was also determined. Missouri prohibits branch banking but allows multibank holding companies to operate. Banks owned by holding companies maintain separate boards of directors and, according to laws and regulations, are supposed to operate in a generally independent fashion. In order to examine the impact of holding company status, holding company affiliated banks are distinguished from independent banks in the analysis.

Because of the highly skewed distributions of the measures of bank deposit size and of total employees to which the bank is linked, logarithmic (base 10) transformations were performed in order to produce more normal distributions useful in regression analyses (cf. Schuessler, 1971:408).

Yet another set of data incorporated in this analysis concerns the profitability of banks. These data come from income reports submitted yearly to federal regulatory agencies. The present analysis utilizes a conventional measure of bank profitability: net income of the bank before taxes and before security gains and losses divided by the total assets of the bank (Reed et al., 1976:434). These data have an advantage over nonbanking corporate profit data in that there is much less variation among banks in accounting techniques due to the common rules and regulations imposed by the federal bank regulators.

The Research Findings

The focus of the analysis is on the determinants of lending patterns among St. Louis banks Initially, differences in loan distributions for banks in different size categories will be examined. Next, a series of regression equations will be presented in order to identify and compare differences in the amount of variance in lending patterns explained by particular variables and sets of variables. Finally, the distribution of loans and other bank characteristics are examined in relation to bank profitability.

a. The distribution of bank loans. The distribution of bank loan capital among lending categories is presented in Table 1 by the size ranks of the banks. For all banks taken together, all three categories of loans to capitalists account for just under one-half (45.8%) of the outstanding loans. The largest single category, commercial and industrial loans, includes over one-third (36.8%) of the loan portfolios. Far smaller amounts are represented by loans to banks and financial institutions (5.8%) and loans for the purchase of securities (3.2%). About one-sixth (15.8%) of the loan totals are invested in home mortgages. Loans not accounted for here are in such loan categories as multifamily residential loans, and credit card and auto loans.

Banks differ in their loan distributions according to their size. The top five banks have concentrated their loans more in lending to capitalists and much less in providing loans for home mortgages. The three categories of smaller banks, which do not differ significantly from each other in their loan distributions, have fewer loans to capitalists and more loans for mortgages. Taken just by themselves, these findings provide some support for the argument that differences in bank lending practices are a function of the size of the bank. Economists interested in banks typically see size as a major determinant of bank performance. In particular, larger banks are seen as trying to emphasize wholesale banking operations with businesses rather than engaging in retail or consumer-oriented banking. It is argued that wholesale banking is both more efficient and more profitable (Starr, 1975:86; Leinsdorf and Etra, 1973:81). However, in Table 1, in contrast to those that follow, data are not presented in a way that allows us to consider the effects of bank size in relation to the effects of the positions of banks within the structure of the capitalist class.

Table 1. The Distribution of Total Bank Loans as of 12/31/75 among Lending Categories by Banks Grouped According to Size

Size Rank of Bank	Loans to Capitalists: % of Loans for Commercial and Industrial Loans	Loans to Capitalists: % of Loan to Banks and Financial Institutions	Loans to Capitalists: % of Loans for the Purchase of Securities	Combined % of Loans to Capitalists	% of Loans for Home Mortgage Loans	Total Amount for All Types of Loans*	(N)
Top 5 Banks	46.9	8.5	5.1	60.5	7.2	$2,136,165	(5)
Banks Ranked 6 to 15	26.6	3.1	.5	30.2	27.3	$522,323	(10)

Banks Ranked 41 to 77	23.8	1.8	1.3	26.9	24.3	$467,052	(37)
	36.8	5.8	3.2	45.8	15.8	$3,872,539	(77)

* In thousands of dollars.

b. Zero-order correlations. In Table 2, the zero-order correlations reveal a generally consistent pattern of support for the arguments developed above. The intensity of a bank's lending to capitalist borrowers is strongly related to the different measures indicating the closeness of the bank's ties to networks of economic power and upper class social interaction within the local capitalist class. The relevant correlations, which include those between loans to capitalists and the range of corporation ties (r = .573), the combined size of linked corporations measured by total employees (r = .547), and upper class social ties (r = .540), are all strong. However, also as expected, a strong positive relationship exists between capitalist-oriented lending and bank size in deposits (r = .402). The pattern of relationships for home mortgage lending is, again as expected, the reverse of that for capitalist lending. These relationships, which are weaker than those for loans to capitalists, indicate that the more closely tied a bank is to the centers of power and prominence, the less involved it is in mortgage lending. Here, however, bank size is only weakly related (r = −.070). Holding company banks are more likely to be involved in loans to capitalists (r = .179) and less likely to emphasize home mortgage loans (r = −.255).

c. Internal class structure and loans for capitalists. In Table 3, the selected regression models, with different combinations of the study variables, allow us to examine statistically the relative contributions of the factors as determinants of the percentage of total loans going to capitalist borrowers. By comparing the increments of explained variation (R^2) added by particular factors when the ef-

(N = 77)

1. Percentage of total loans outstanding on 12/31/75 to commercial and industrial borrowers (except for real estate), to banks and other financial institutions and to brokers and nonbrokers for the purchase of securities.
2. Percentage of total loans secured by one to four family residences.
3. Number of different Top 350 St. Louis-based corporations with which bank is interlocked through one or more of its directors.
4. Total combined number of employees in all Top 350 local corporations with which bank is interlocked (logarithmic transformation, base 10).
5. The proportion of the bank's directors who belong to one or more of the five leading upper class organizations in the St. Louis area.
6. The total deposits of the bank as of 12/31/75 (logarithmic transformation, base 10).
7. The holding company status of the bank in 1975: banks affiliated with holding companies are coded 1; independent banks are coded 0.

fects of others are controlled, we have a standard for evaluating the relative strength of different influences.

The most notable discoveries in Table 3 are, first, that the explanatory model is quite strong ($R^2 = .436$) and, second, that the measures for capitalist class structure emerge as the major determinants of the relationship. When the explanatory power of the three measures of capitalist class structure (in Equation C, $R^2 = .434$) is compared to one with the two measures of bank size and holding company status (in Equation D, $R^2 = .172$), the strength of the class structure measures is apparent. This comparison is examined here in terms of how each equation relates to the full five-variable equation (Equation A). While the class structure measures produce an increment in explanatory power of 25% over just the institutional characteristics alone (Equation A − Equation D = .254), essentially no increment is associated with bank size and holding company status in addition to that explained by the class structure measures alone (Equation A − Equation C = .002).

Almost all of the explanatory power associated with capitalist class structure comes from two measures of corporation interlocks rather than from the measure of upper class social ties. The explanatory increment for the full five-variable model associated with upper class social ties (.010) is considerably smaller than that for the number of corporate interlocks (.029) and the total number of employees (.070). However, the weakest increments are those associated with bank size and holding company status (both are .001). Based on those increment differences and on the standardized regression coefficients, the measure of the combined total number of employees in interlocked corporations is the strongest determinant relative to other variables in the model.

d. Home mortgage loans. In general, home mortgage lending follows a parallel but opposite pattern from that of loans to capitalists. As shown in Table 4, the overall model is generally quite strong ($R^2 = .328$) in predicting the percentage of a bank's total loans going to home mortgages. While once again a much larger

[1] Variables are described in Table 2.

increment in explanatory power is associated with the capitalist class structure measures (.264), the bank size and holding company measures do exhibit some independent strength here (.094). Nevertheless, when the effects of the other measures are controlled, bank size is actually positively related to mortgage lending activity. The measure of total interlocked employees has the greatest overall strength (an increment of .104 over the other four variables). Ties to upper class social organizations would appear to have a very weak independent influence in this instance.

e. Bank profits and loans to capitalists. The one empirical issue left to consider concerns the relationship between lending patterns and bank profitability. Table 5 presents the zero-order correlations between the study variables and profitability. The general finding is one of almost no relationship between profits and either the proportion of loans to capitalists (r = .016) or the proportion of loans for home mortgages (r = .010). Thus, there is no evidence here either that greater corporate or class interlocks or "blue-chip" corporate lending leads to high profits or that home mortgage lending hurts bank profits. This interpretation finds further support from several regression equations, not shown here, that examine the combined effect of the variables. For example, when the measures of loans to capitalists and loans for mortgages are examined together, the resulting regression equation explained virtually none of the variance in profitability ($R^2 = .0003$). If the profits of the 25 members of the Federal Reserve System are adjuisted upwards by 10% to reflect the reported disadvantages for such member banks which must maintain sizable interest-free balances in the Federal Reserve System, the results are only marginally affected. Thus, bank profitability is not explained by the measures incorporated in this study.

Discussion and Conclusion

This study has focused on the lending decisions of banks as important social consequences that are associated with the internal structure of the capitalist class. The findings presented here provide strong support for the thesis that bank lending practices are influenced by the linkages that banks have with the centers of economic power and upper class social interaction within the capitalist class. These data indicate that those banks which are most closely tied to these centers serve, in effect, as capital-accumulating appendages of core capitalist groups. The consequences of having strong linkages to such groups is, thus, that banks tend to direct their loans in ways that best meet the capital needs of these groups. The banks with the most extensive ties to the centers of the class have concentrated their loans with capitalist borrowers and have avoided loans in categories such as home mortgages that indicate a broader distribution of loan capital within a community.

These patterns appear to be relatively independent of the size of the banks. The banks emphasizing lending to capitalists are those ones whose directors are tied to numerous local corporations which represent major concentrations of economic power and, to a lesser extent, are tied to the most exclusive upper class social circles. In contrast, banks that occupy more marginal positions within the structure of the class, even if they are relatively large, are much less engaged in lending to capitalists and much more engaged in mortgage lending. An important part of the findings is that the dimension of corporate economic power, as measured by the total number of employees in corporations interlocked with each bank, is a major determinant in relation to other network characteristics of the flow of capital out of banks.

The director interlocks between large corporations and certain banks thus seem to embody the "personal union" of overlapping propertied interest that Hilferding (1923) portrayed as rising to dominance in capitalist societies. The mechanism of such dominance that is at issue here is the command of "finance capital," which Hilferding defined as "capital controlled by the banks and utilized by the industrialists" (Sweezy, 1942:266). The St. Louis data reveal that this personal union of bank and corporate interests at the centers of economic power and social prominence within the capitalist class is associated with a major flow of loan capital from the banks to corporations and other related borrowers.

The linkages to banks enable leading

only large corporations but also investment bankers and other private investors (Soref, 1980). Much of the money in commercial banks comes from a diverse range of deposits, including individual checking and savings accounts, government accounts, certificates of deposit held by pension funds and other similar nonbusiness institutions, accounts of churches and other private organizations and small business accounts, and would not be as available for corporate loans if banks tied to corporate interests did not serve to accumulate these funds (Reed et al., 1976:74–9).

This analysis does not support the arguments of Hilferding regarding the ascendancy of bank dominance over corporations. The argument offered here is that it is not likely to be useful to attempt to locate the base of these power relationships in either banks or corporations as distinct organizations. Rather, I have portrayed a model of capitalist class coordination in which control is most likely to be located in larger structures of propertied interests that tie banks and corporations together. The data presented here are not sufficient to validate this model in any ultimate sense. Certainly, any thesis of bank dominance is contradicted by the finding in this analysis that bank profitability is not associated either with extensive corporate interlocks or with patterns of concentrated lending to capitalists. Nevertheless, it would be arguable that these findings would be consistent with a model of corporate dominance over banks if it could be shown that the corporations most interconnected with banks, and most favored in the receipt of bank loans, tended to be more profitable. In such a model, corporations might be seen as forcing banks to provide loans to them on advantageous terms, thus, making the banks less profitable. However, such an interpretation is highly tenuous given the lack of data suggesting that corporations are in a position to dominate and control banks (Kotz, 1978; Soref, 1980).

These patterns in the command of capital are not only important in regard to the operation of banks, but also relate to the health and vitality of the entire metropolitan economy. When certain borrowers gain sufficient capital through loans, a normal consequence is that other borrowers are denied such capital. Moreover, in St. Louis, which can be characterized as a declining industrial area, the concentration of loans found among capitalist borrowers probably represents a significant outflow of capital from the metropolitan area. Corporate investments are most likely to be made in higher growth areas, and since large corporations operate on a multistate and often multinational basis, they are in an advantaged position with respect to the transfer of capital investments. Here, it should be noted that all interpretations regarding the geographic transfer of capital must necessarily extend beyond the data presented in this analysis. It is to be remembered that the data used here only identify the categories of borrowers and do not reveal the particular uses or the geographic locations of investments resulting from these loans. Nevertheless, there is considerable evidence that in the last several decades the largest St. Louis based corporations have moved a major share of their investments and jobs out of the St. Louis area (Defty, 1975; *Business*

Week, 1976). The transfer of capital out of the St. Louis area has also been clearly documented in terms of the mortgage lending activities of St. Louis financial institutions (Ratcliff, 1977).

The evidence thus suggests that St. Louis, despite its image as a "declining" older industrial metropolis, is actually a producer of a net capital "surplus" that is exported for investment elsewhere, presumably especially in the "Sunbelt" and other high growth areas. This outflow of capital certainly does not represent a lack of investment needs in the St. Louis area. If St. Louis were to reverse the long-term decline in the number of manufacturing jobs, and if the housing needs of the area's residents were to be met, sizable investments would be an absolute necessity. The viability of the St. Louis area, as is the case with other older industrial areas, is very much dependent on the success of locally oriented investors in obtaining sufficient investment capital. Given these currents of investment and disinvestment within an older metropolitan area, the leading St. Louis capitalists appear to be playing complex and even contradictory roles. At the same time that they are most closely tied to locally based structures of power and prominence, they also appear to be most involved in the outward flow of investments from the metropolis. These tensions reflect the dual needs of the leading capitalists to protect both their local class bases and their long-term interests by taking advantage of national economic trends (Ratcliff, 1980a). Because many of the banks most centrally located in the capitalist class are also the ones that are progressively growing larger and more powerful among banks, the prospect for the future is that the imbalances of capital concentration and capital disinvestment will grow even more severe.

MANUSCRIPTS FOR THE *ASA ROSE SOCIOLOGY SERIES*

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Suzanne Keller, Department of Sociology, Princeton University, Princeton, NJ 08540.

UNCONFOUNDING THE CONFLUENCE MODEL: A TEST OF SIBSHIP SIZE AND BIRTH-ORDER EFFECTS ON INTELLIGENCE*

LALA CARR STEELMAN AND JAMES A. MERCY
Emory University

American Sociological Review 1980, Vol. 45 (August):571–582

This paper explores the theoretical validity of the confluence model in explaining the effects of sibship size and birth order on intelligence. Using a nationally representative sample the effects of age, sex, marital disruption, socioeconomic status, race, and other potentially confounding variables, unincorporated in other studies, are controlled. The results suggest that (a) the inverse relation between sibship size and IQ lessens for the economically advantaged, (b) the only child breaks the otherwise consistent linear decline between sibship size and IQ in the below-poverty condition only, (c) the nonteacher handicap for only children is questionable, and (d) close spacing, as Zajonc defines it, may have detrimental consequences for children irrespective of birth order.

INTRODUCTION

The confluence model, an explanation of cognitive differences, is in vogue today. The objective of this paper is to examine the impact of its two primary variables, sibship size and birth order, on the intellectual development of children (Zajonc and Markus, 1975).

The problem with which the confluence model deals has generated a considerable body of research; however, further study is justified for two reasons. First, previous research has yielded inconsistent and even contradictory findings. Secondly, the theoretical explanations and hypotheses offered for the results derived are inconsistent. The source of these deficiencies stems from a lack of methodological rigor, particularly in regard to the lack of control over important alternative explanatory variables, the nature of the samples used, and the use of different measures of the dependent variable (i.e., intellectual development) from study to study.

Because of the methodological shortcomings of prior studies, this problem requires rethinking and redoing. The strategy of this paper is to take a critical look at explanations advanced by others to account for sibship size and birth-order effects through the analysis of a more appropriate and representative data source. Our study addresses (under more stringent conditions than have been used previously) the validity of the confluence model in predicting cognitive outcomes.

THEORETICAL REVIEW

Many previous scholars have offered ad hoc explanations to account for the effects of sibship size and birth order on intelligence. The bulk of the evidence suggests that birth order taken alone inversely relates to intellectual performance, and, similarly, sibship size taken alone inversely relates to intellectual performance. To explain these patterns, several hypotheses have been postulated: physiological, differential treatment of children by parents, confluence model, and admixture explanations.

The physiological explanation of birth-order effects proposes that the mother's uterus becomes fatigued with each successive pregnancy through loss of essential nutrients, and that this depletion leads to eventual psychological differences (Belmont and Marolla, 1973; Bayer, 1967). Record et al. (1970) cite evidence

The authors wish to express their gratitude to Alan Lizotte for his helpful criticisms and guidance. This work was, in part, supported by NICHD contract #N01-HD-92802. We are grateful to the principal investigators of this project, John Doby, S. Mitra, and Martin Levin for making these data available to us. We would also like to thank Carl W. Tyler, Jr., Rose McGee, Maggie Stephens, and two anonymous reviewers for their assistance.

taken from twin studies which make this argument less viable. Twins score lower than nontwins on IQ tests. But twins whose cotwins die during the first four weeks after birth score equal to nontwins (Record et al., 1970). The authors suggest that this points to the importance of the postnatal environment in affecting cognitive outcomes (Record et al., 1970). However, nutrients are not necessarily distributed evenly between twins in the prenatal environment; thus, the possibility that cognitive differences may be linked to prenatal development still remains (Bulmer, 1970:34–5). Although the physiological view may have validity, no attempts are made to deal with it in this paper because of inadequate information.

Another explanation offered is that, as family size increases, deficiencies or changes in parental care take place. When families grow, parents have less time to devote to later children, thus the latter spend more time in the company of siblings (Nisbet and Entwistle, 1967). This time factor is particularly relevant to the mother since she has traditionally been held responsible for caretaking duties (Kagan, 1977). Parental expectations may also vary by birth order with parents showing greater concern over the accomplishments of the early born, especially the firstborn, and becoming increasingly more lax in their attitudes towards achievement with each new child (Sampson, 1965). Data used to substantiate this position fail to measure whether or not differences in parental treatment actually occur and then translate into test differences. They just assume that they do.

The effect of birth order by itself on intellectual performance generally indicates that firstborn excel over others on ability tests (Altus, 1966), eminence (Schacter, 1963), likelihood of earning a doctorate (Bayer, 1967), college attendance (Bayer, 1966; Glass et al., 1974) and verbal ability scores (Glass et al., 1974). But Glass's (1974) findings only held for those from higher socioeconomic backgrounds, and Schacter (1963) attributed his result to the marked surplus of firstborn in the college population cohort. As an independent variable, family size (defined as the number of siblings) consistently appears to relate negatively to intellectual level (Anastasi, 1956; Zajonc et al., 1979). Nisbet and Entwistle's (1967) inquiry into size effects on the test scores of Scottish children found the typical inverse relation, but the impact was more pronounced in the lower class than in the higher class. Similarly, Marjoribanks et al. (1975) found that sibsize effects were ameliorated by the social class background of the test-taker. Rankin et al. (1979) tested the impact of sibsize on the test scores of Samoan children and found a curvilinear relation with those from both larger and smaller families underscoring those in between. The findings on size and order effects are discrepant, especially in the presence of social class indicators, but they generally convey this message: those reared in small families or those born early score higher on tests of intellectual development. Interpretation of these early efforts is made difficult by the strong interrelationship between sibship size and birth order. Probably because of small sample sizes, some of the pioneer studies did not examine the independent effects of size or order on intellectual performance while holding the other variables constant (Adams, 1972).

It took Belmont and Marolla's (1973) study to pave the way. Their investigation delved into the performances of 386,114 Dutch men, born between 1944 and 1947, who represented the entire male population for this age cohort on the Raven Progressive Matrices. During the time that these subjects were born, a severe famine took place in the Netherlands. Nevertheless, maternal malnutrition was not found to affect the intellectual performance of survivors at military age (Stein et al., 1972). In this study two ideas were tested: whether there were birth-order effects irrespective of sibship size and whether there were size effects irrespective of birth order (Belmont and Marolla, 1973). Next, mean Raven scores were examined under varying conditions of father's occupational status, defined as manual, nonmanual, and farm. Birth-order effects persisted across class conditions, while size effects diminished only under the farm condition. Generally, the data indicated separate effects for each variable. This meant that the firstborn scored higher than secondborn and so on successively, and, further, that the firstborn in small families scored higher than the firstborn in large ones. One irregularity from this otherwise consistent linear decline was the only child, who, given the trend, should have scored highest, but who, instead, ranked parallel to the firstborn of four. Also, the rate of decline for the last born, in relation to the next to last born, was greater than for other adjacent siblings.

In another study, Breland (1974) elaborated on the effects of sibship size and ordinal position on student performance on the National Merit Scholarship Qualifying Test taken by gifted tenth- through twelfth-graders. He concluded that the early born from small families scored highest and the later born from large families scored lowest on verbal subtests, but not on nonverbal ones. He too found the only child exception. Existing relationships were neither altered by the presence of the covariates (family income, mother's age, mother's education and father's education), nor by the sexual composition of the sibship. These two foregoing studies added new dimension to the problem sparking the acclaimed and tentative theory that follows.

In response to these new findings, Zajonc and Markus (1975) proposed the confluence model. Under this model, a child's intelligence is seen as a function of the intellectual environment in which he grows up. "Intellectual environment can be thought of in this context as being some function of the absolute intellectual level of its (the family's) members" (Zajonc, 1976:227). Membership includes the child. Children are not born with the same intelligence as adults; they must develop it. Therefore, sibship size bears directly on a child's development because the greater the number of children relative to the number of adults, the less beneficial the intellectual milieu. The birth-order effect, however, is an indirect product of spacing. If one considers a pair of siblings, the younger one would suffer more from close spacing than the older one. To substantiate this point, Zajonc (1976) observed that birth-order effects happened in some samples but not in others. When they did not occur, Zajonc (1976) attributed it to wider spacing practices. To assess this possibility, he used birthrates as an indirect measure of spacing and assumed that the higher the birthrate, the shorter the average intervals separating children. Comparing the birthrates for samples where birth-order effects did and did not occur, Zajonc (1976) found that birthrates were indeed lower for the latter samples, a difference he used as support of the spacing/birth-order factor.

One other factor is included in the model to account for the only and last child exceptions. As it has been explained so far, the confluence model would predict that the only child should rank highest on intellectual performance because the only child is reared in an environment undiluted by the presence of other children. Added to the model, then, is the tutoring factor; namely, that children profit from teaching younger children because it gives them the opportunity to experience the active part of learning. The benefits of being an only child are, hence, counteracted by the only child's nonteacher handicap (Zajonc and Markus, 1975). Similarly, the steeper drop in test scores of the last born as compared to other adjacent siblings is attributable to the same handicap. But as Falbo (1978) observes, the nonteacher handicap does not explain why the secondborn in families of two outperform only children. Zajonc (1976) took the confluence model, applied it to SAT outcomes, and found a good fit. Davis et al. (1977) also found support for the confluence model on Israeli eighth-graders' performances on mathematical subtests. However, in their study the last born sometimes showed an unanticipated upswing in performance. Two studies, in which lower class subjects were excluded from the sample, found only a weak connection between the confluence model and test performance (Cicirelli, 1976; Grotevant et al., 1977). Though the data reviewed so far generally support the confluence model, many of their implications remain untested. This model awaits a rigorous test that uses more precise measures of the crucial factors involved.

Recently reawakened interest in birth-order effects has prompted critics to exclaim, "Not here, not now!" (Schooler, 1972). Opponents of birth-order effects have tried to erase fascination with it, arguing that the correlation between birth order and intellectual competence is due to class differences in fertility. The role that parent's social class plays on a child's progress is enormous. Kagan (1977) called it one of the few firm facts in psychology. Larger families are more likely to come from the lower class; thus, size effects may be mediated by socioeconomic differences.

Page and Grandon (1979) noted that interfamily differences, like socioeconomic status, might play a larger role on cognitive development than the confluence variables. They claimed that the apparent effects of family size, derived from aggregate data, far from explaining population differences, are better accounted for as a result of group admixtures, defined as differences such as social class or ethnic group membership. Their study shows that in the presence of social class indicators, the importance of the confluence model variables is diminished. Using data taken from two large samples of United States and Colombian student test-takers, the confluence model explained less than 5% of the variance in the United States sample and less than 1% in the sample of Colombian students (Page and Grandon, 1979; Velandia et al., 1978).

Similarly Kunz and Peterson (1977) found that size and order effects disappeared when controlling for social class. Their data consisted of the grade-point averages of over 6,000 high school students from across the nation. Using linear regression techniques, they examined the effects of class, size, and order on grade-point variation. Class accounted for a significant portion of the variance (still, only 6%) while the other two predictors had little explanatory value. Grade-point average, nonetheless, is a weak measure of cognitive ability when compared with standardized test scores.

So the results on sibship size, birth order and social class effects are mixed. Belmont and Marolla (1973) found consistent effects across classes, Breland (1974) found effects across classes but only on verbal subtests, and Kunz and Peterson (1977) found effects vanishing upon control of social class. Others (Page and Grandon, 1979; Velandia et al., 1978) have shown that the explanatory power of the confluence model diminishes in the presence of socioeconomic and other between-group differences.

Another source of confusion in prior studies is their failure to take other explanatory factors, aside from socioeconomic status, into account. Zajonc (1976) acknowledges that differences in psychological outcomes might be due to factors outside the confluence model. Two of these confounding factors are race and marital disruption. The factors by no means exhaust the list of plausible alternatives. They represent only two of many factors. The consequences of marital disruption (widowhood, divorce, separation, remarriage, and step-parenthood) have all been linked to the impeded cognitive development of children, since parents serve as role models, resource providers, nurturers, and socializers. For one person to manage all of these diverse tasks alone is difficult. Zajonc (1976) fits marital disruption into the confluence model saying that the intellectual environment is dampened by parent absence because it lowers the number of adults figuring into the overall intellectual average. Unfortunately, one cannot assume that marital disruption distributes itself evenly across family sizes. There is evidence to the contrary. For example, Falbo's (1978) recent reinterpretation of Breland's (1974) data highlights the uneven nature of this distribution. Using census figures for women who had completed the childbearing years, Falbo (1978) estimated that only children were 5% more likely to reside in father absent households than multiple children. This factor alone accounted for 25% of the only child deviation from the inverse linear trend that Breland (1974) found connecting sibship size to test performance.

Similarly, race may influence the findings because blacks show both higher fertility and lower test performances than whites. Zajonc (1976) subsumes race under the confluence model noting that blacks are more likely than whites to be located in family configurations which are less conducive to development. The black configuration is apt to be characterized by father absence and closer spacing between siblings. Failure to control for these alternative factors in prior studies makes their results somewhat suspicious. Many of the foregoing problems are solved in this paper because of the quality of the sample studied. These new data permit a stronger test of the confluence model and the competing explanations given to account for sibship size and birth-order effects on intellectual capacity.

SAMPLE

The data used in this paper come from Cycle II of the Health Examination Survey. Fieldwork for this project was conducted from July, 1963, to December, 1965. The survey utilized a multistage, stratified probability-sampling technique of loose clusters of persons in land-based segments. Of the originally selected subjects, 96% were included in the final sample. The sample is thought to be highly representative of noninstitutionalized American children, excluding Indians living on reservations. These youths range in age from 6 to 11, which is a limitation to this study because they may represent incomplete families. Nevertheless, information on the family structure at the time of the child's examination is available.

The tests used to measure the dependent variable are the child's standardized scores on the Wechsler vocabulary and block-design subtests.[1] These exams are normalized by four-month age intervals and adjusted for sex differences. Trained psychologists administered them to the subjects individually.

Other relevant information collected in the survey include birth certificate information and interviews with the child's parents. The cases that were picked for analysis provide a tighter test of the confluence model through the elimination of confounding factors.

Only the following subjects are included:

1. Whites.
2. Children residing in homes with both of their natural parents and no other adults over 20 years old (this stipulation removed another possible contaminant—the possible influence of extended family members or other adults).
3. Children whose parents answered no to the following question, "Are there children living outside the household?"[2]

These criteria were met by 3,428 subjects. Since the oldest child could be no older than 20, densely spaced families are likely to be overselected. Zajonc (1976) anticipated birth-order effects under conditions of close spacing, which is defined as high birthrates. This sample comes from a cohort whose birthrates were high ranging from 23.1 to 24.2 by Vital Statistics estimates (U.S. Dept. HEW., 1969). For all of the above reasons, this sample should provide a stronger test of the confluence model than has been done previously. For further description of these data, see NCHS publications (1967; 1971a; 1971b; 1972a).

ANALYTIC TECHNIQUE

The data are analyzed in three phases. First, the IQ means are cross-classified by sibship size and birth order while controlling for poverty status (defined as above and below $4,000 annual family income). This cutoff point was chosen because it represents the nearest category to the poverty threshold in 1964.[3] This distinction provides the clearest separation of the lower from the middle and upper classes. In the second phase, a regression analysis was performed. This analysis was done separately for above- and below-poverty status subjects. It was decided that the cross-classification tables, when controlling for poverty status, revealed patterns which were different enough to justify such an approach. In the third phase, a partial correlation analysis was done (again, separately for above- and below-poverty groups) to clarify the magnitude of the effect of each of the independent variables on the dependent variable, while controlling for the presence of other variables in the models.

---

[1] These subtests represent only two of the 12 tests that comprise the Wechsler Intelligence Scale. The sum of the scores for the vocabulary and block design subtests correlate .88 with the full Wechsler Intelligence Scale according to NCHS (1972b) estimates.

[2] This was done because the measure of birth order was the age rank of the child among children under 20 years of age in the household. Therefore, only cases where birth order was equal to age rank are included.

[3] Given the constraints of the data, we decided that the fairest measure of poverty status is based on the average family size in our subsample which is 5.7. using estimates that represent the population as of March, 1964 for family sizes of five and six ($3,685 and $4,135, respectively), we derived an estimate for a mean family size of 5.7 by taking the difference between income values for families of five and six, multiplying that difference by .7, and adding that

For the purposes of the regression and correlational analyses, the dependent and independent variables are operationally defined in the manner described in Table 1.

Table 1. Variables Used in Regression and Correlational Analysis and Their Operational Definitions, Means, and Standard Deviations

Status Level	$\bar{X}$	S.D.
Below Poverty Status		
IQ Scores, Index of Intellectual development (IQ)—sum of the Wechsler Vocabulary and Block Design Test Scores	94.29	13.87
Sibship Size (S)—ranges from 1 to 16	4.59	2.27
Birth Order (B)—ranges from 1 to 10+	2.47	1.54
Income (I)—1 = < $500; 2 = $500–999; 3 = $1,000–1,999; 4 = $2,000–2,999; 5 = $3,000–3,999	3.94	1.17
Mother's Working Status (M)—the usual activity of mother; 0 = mother working, 1 = mother not working	.80	.40
Above-Poverty Status		
IQ Scores, Index of Intellectual Development (IQ)—sum of the Wechsler Vocabulary and Block Design Test Scores	105.58	13.03
Sibship Size (S)—ranges from 1 to 11	3.61	1.63
Birth Order (B)—ranges from 1 to 10+	2.25	1.23
Income (I)—6 = $4,000–4,999; 7 = $5,000–6,999; 8 = $7,000–9,999; 9 = $10,000–14,999; 10 = $15,000+	7.82	1.09
Mother's Working Status (M)—the usual activity of mother; 0 = mother working, 1 = mother not working	.72	.45

RESULTS

In Table 2a the mean scores are presented by sibship size and birth order. A check of the marginal mean scores shows a monotonic linear decline in score by birth order and a monotonic linear decline in score by sibship size with the exception of the only child. This pattern adheres to confluence model predictions. But closer examination of the within-cell scores shows an inconsistent effect of birth order within sibship sizes. Marginal means which suggest birth-order effects are a function of the correlation between sibship size and birth order.

Tables 2b and 2c illustrate the array of means cross-classified further into above- and below-poverty conditions. For the above-poverty group, IQ scores show a consistent mean decline by size, with no exceptions. For the below-poverty group, the same pattern exists except for the only child who scores parallel to the firstborn of five. However, the birth-order effect fails to hold within sibship sizes for either the above- or below-poverty status groups. Clearly, controlling for class considerably alters the nature of the relationship between sibship size and IQ as is further demonstrated by an inspection of the zero-order correlation coefficients presented in Table 3. These figures indicate that sibship size has a much stronger negative correlation with IQ in below-poverty (−.23) than in above-poverty groups (−.13). Notice that this result holds despite the deviation of the only child from a linear trend in the below-poverty condition.

Table 4 shows the full and the final regression models for prediction of IQ scores. Unstandardized regression coefficients are used to measure effects. Inspection of these results demonstrates that income and sibship size are the most powerful predictors of IQ scores of the variables included in the final model for

---

figure to $3,685. This yields an approximate poverty income cutoff point of $4,000 which corresponds to one of the categorical cutoff points in our data (Orshansky, 1965).

Table 2a. Mean IQ by Birth Order by Sibship Size

	Birth Order						
Sibship Size	1	2	3	4	5	6+	Row Mean
1	105.90	—	—	—	—	—	105.90

both below- and above-poverty conditions. Closer scrutiny of these coefficients shows that the gradient of income effects on IQ scores is greater in above- (3.12) than in below-poverty groups (2.60). Conversely the gradient of the effect of sibship size appears to lessen more in the above- (−1.00) than in the below-poverty group (−1.22). However, a test of the null hypothesis that the corresponding slopes for income and sibship size are equal across the models cannot be rejected on the basis of statistical significance (Dixon and Massey, 1969:209). While these results suggest a trend in which the gradients of the effects of income and sibship size on IQ scores are changing as social class increases, the result may be due to chance.

Another important distinction between the two models is the inclusion of mother's working status in the final model for the above-poverty group and its absence in the below-poverty final model. Only in the above-poverty group does the mother's continual presence in the home relate positively to IQ.

The variance explained by the confluence variables, sibship size and birth

Table 3. Zero-Order Correlation Coefficients

	Sibship Size	Birth Order	Income	Mother's Working Status
All Subjects				
IQ	−.20	−.07	.38	.01
Sibship Size		.65	−.19	.12
Birth Order			−.02	.00
Income				−.03
Mother's Working Status				
Below-Poverty Status Subjects				
IQ	−.23	−.09	.24	−.03
Sibship Size		.70	−.13	.06
Birth Order			.03	−.05
Income				.10
Mother's Working Status				
Above-Poverty Status Subjects				
IQ	−.13	−.05	.27	.03
Sibship Size		.64	−.05	.12
Birth Order			.03	.00
Income				.01
Mother's Working Status				

order, amounts to 4.5% among all subjects when these variables are considered by themselves in the model. This figure approximates that of the 4.6% of the variance explained found by Page and Grandon (1979) owing to confluence variables in a sample of U.S. high school students.[4] However, when comparing the amount of variance explained by sibship size and birth order across poverty status, we find they account for 6.1% in the below-poverty group and only 2.0% in the above-poverty group. Sibship size accounts for the great majority of the variance explained in both cases.

Thus, the regression analysis reveals five important results. First, income and sibship size, in that order, are the most important predictors of IQ scores in both models. Second, birth order fails to relate significantly to outcomes in either model. Third, a comparison of the corresponding slopes of income and IQ in the two models reveals the gradient of their effects is not statistically different. However, an interesting trend is suggested. Fourth, mother's working status is a significant independent variable only in the above-poverty group. Fifth, the confluence model has greater explanatory power among below-poverty status subjects than among those in the above-poverty status.

Tables 5 and 6 show the results of the correlations of each of the independent variables with IQ scores while systematically partialling out the effects of the other independent variables. Table 6 shows that, when controlling for all the variables in the below-poverty condition, only income and sibship size correlate with IQ significantly. This result is consistent with the corresponding regression model for the below-poverty group. The contribution of income to variance reduction in the full model (.21) is slightly greater than that of sibship size (−.18). Similarly, Table 7 shows that all of the third-order partial correlations in the above-poverty group are significant, with birth order barely significant. But in this case income's contribution to variance reduction (.26) is greater relative to that of sibship size (−.12) as compared with the findings in the below-poverty condition.

To determine whether income and sibship size provide a significantly better or worse fit of the data in the below- than in the above-poverty group, a test of the null hypothesis that the corresponding partial correlation coefficients for income and sibship size in the two models were equal was performed (Blalock, 1972:406). This

---

[4] Page and Grandon (1979) also included "birth order squared" and "last child" among the confluence variables. However, neither variable contributed more than a negligible amount to the variance explained.

Table 4. Unstandardized Variables and Their Standard Errors in Parentheses Predicting IQ Scores

Independent Variables	Full Model	Final Model
Below-Poverty Status		
Intercept	90.5104	89.6383
Income	2.5313 (.5305)	2.6084 (.5184)
Sibship Size	−1.5531 (.3837)	−1.2235 (.2667)
Birth Order	.7042 (.5625)	
Mother's Working Status	−0.9899 (1.5369)	
Adjusted R²	.0962	.0957
Above-Poverty Status		
Intercept	83.8592	83.8692
Income	3.0875 (.2115)	3.1206 (.2107)
Sibship Size	−1.2130 (.1863)	−1.0008 (.1422)
Birth Order	.4302 (.2442)	
Mother's Working Status	1.3750 (.0473)	1.2847 (.5163)
Adjusted R²	.0880	.0873

was done while controlling for all other variables in the final model. Only the partial correlation coefficients for sibship size for the two models are significantly different ($p < .05$). This suggests that size provides a significantly better fit in prediction of IQ in the below-poverty group than in the above-poverty group.

The following results appear to be the most interesting and important: first, the marked deviation of the only child from the linear pattern appears in the below-poverty group but not in the above-; second, the absence of a significant effect of birth order in either of the final models; third, the consistent effect of income in both the terms of its gradient and the fit it provides in the below- and above-poverty groups; fourth, the inconsistent effect of sibship sizes in terms of the fit it provides in below- as compared to the above-poverty group, but not in terms of its gradient; fifth, the smaller contribution of the confluence variables to the amount of variance explained among above-poverty status subjects as compared with those in the below-poverty status; finally, the negative influence of a mother's working in the above- but not in the below-poverty groups is noteworthy.

CONCLUSIONS

These data partially verify and partially fail to confirm aspects of Zajonc and Markus's (1975) confluence model. They also suggest paths for future research. Under the confluence model, sibship size bears directly on intelligence irrespective of other factors. Since these effects occur in spite of socioeconomic location and in spite of the elimination of other confounding factors, sibship size seems to have an important independent inverse impact on IQ; however, the absence of a birth-order effect weakens the confluence model's validity.

Whether or not size effects occur because of the dilution of the intellectual milieu or because of dilution of factors such as economic resources, for example, remains to be seen. But inasmuch as income is the most powerful predictor, the role that other environmental forces play on a child's test performance stand out. The greater importance of this indicator of social class supports Page and Grandon's (1979) admixture explanation of intellectual differences.

Since family size effects are less pronounced in the above-poverty model, an interaction effect might be posited for future research. For the low income group each additional child drains money from an already squeezed budget, whereas the costs of additional children in high income families may be more easily absorbed. For these reasons, further analysis should include a breakdown of the higher income groups into subgroups to determine if size effects lessen even more with ascension up the income scale.

Some other major components of the confluence model are questioned by our findings. Insofar as the sample analyzed contained relatively closely spaced children (at least equivalent to Zajonc's [1976] definition of closeness), birth-order effects would be expected. They did not occur. If anything, their influence, though insignificant, was the reverse of that expected. But these birth-order patterns do not refute the spacing argument. Rather they suggest that close spacing produces detrimental outcomes for children, irrespective of birth order. Family density may, in part, account for the negative sibship size impact, since as sibship size increases, birth intervals between children invariably decline. What insignificant birth-order effects suggest is that the advantages that other scholars ascribe to an early birth position in the sibship hierarchy are to a great extent exaggerated. They also erode the long held belief by psychologists that individual attention during early and extremely sensitive phases of growth has a critical, irreversible impact on child development.

However, another vivid possibility exists to account for the absence of a birth-order effect in this study. In Zajonc's review (1976) in which he compared samples where birth-order effects did and did not occur, he originally attributed the difference to spacing practices at the aggregate level. Admittedly, birthrates only roughly assess spacing patterns. There is, yet, another striking difference in the samples summarized—the age of the test-taker. In this study and others where birth-order effects did not occur (with the exception of Kunz and Peterson [1977]), the test-takers ranged in age from 6 to 14 (Zajonc et al., 1979). In studies where effects occurred, even if modest, tests were taken by older teenagers. So there could be developmental differences with birth order exerting a "sleeper effect" on intelligence—not appearing until later in life with shifts in cognitive developmental stages.

In addition, the nonteacher handicap explanation of the only-child exception is inapplicable to these data. Since it only occurs in the below-poverty group and since the discontinuity there is so striking, there may be something about being an only child in a low income family that counteracts the advantages of small sibship size. For example, reasons for having one child may vary by socioeconomic position. Also, the only child in a high income family could experience both the advantages of unshared resources plus compensatory activities provided by parent's money such as kindergarten where interaction with peers is available. By contrast, the only child in a low income family lacks contact with siblings and may, because his parents cannot afford it, also lack alternative activities where exposure to other peers is available.

If the tutoring target factor were correct, then last-born children would score lower than older ones because they did not have a younger sibling to teach. Often in this work, the reverse occurs with youngest children having the highest mean IQ within their sibship size group, thus giving support to the idea that what makes only children in low income families different is their isolation from other children rather than their nonteacher handicap.

In regard to the differential treatment explanation, the measure used in this analysis is so crude that only speculations are made to account for its impact. Assuming that mothers who work have less time to spend with children, then, this factor should influence IQ across class conditions. It does not, appearing only in the above-poverty group. This finding may suggest that time spent with the child is not as important as the quality of the interaction between mother and child. The higher income mother is apt to possess knowledge and skills that make her a better coach than her lower income counterpart. Keeping company with her may stimulate a child's intellectual development. Until better measures of the quality of interaction are taken into account, though, this suggestion is mere speculation.

Certainly, this research only scratches the surface of a very complex problem. It appears that sibship size, because children must share resources, intellectual or other, among themselves, is important. This sharing may also impinge on the quality of interaction.

RACE AND SEX DIFFERENCES IN CAREER DYNAMICS*

RACHEL A. ROSENFELD
McGill University; and the National Opinion Research Center, University of Chicago

American Sociological Review 1980, Vol. 45 (August):583–609

In this paper, career differences by race and sex are analyzed. Careers are defined as trajectories of socioeconomic status and wages and are described by a linear differential equation model. It is assumed that the different groups defined by race and sex tend to be in different labor markets and economic sectors and to face different opportunity structures even within labor market divisions. This assumption guides predictions for and interpretation of results with respect to various aspects of career inequality: initial status and wage level; potential status and wage levels; effects of human capital, family background, and family of procreation variables on initial and potential wage and status levels; speed of advancement. Pooling of cross-sections and time-series techniques are used to estimate the model, with data from the National Longitudinal Surveys of the Labor Market Experience of Young Men and Women.

In the last decade, sociologists have made extensive use of the status attainment approach, which focuses on the effects of individual-level characteristics on achievement, to monitor racial and sexual inequality. (See, for example, the papers in Hauser and Featherman, 1977.) Even more recently, sociologists have begun to investigate the extent to which differences in labor market positions result in the observed inequality by sex and race (e.g., Bibb and Form, 1977; Beck et al., 1978a; 1978b). Spilerman has suggested (1977:551) "the notion of the career [job history] as a strategic link between structural features of the labor market and the socioeconomic attainments of individuals."

With few exceptions (e.g., Sørensen and Tuma, 1978), however, the empirical research on socioeconomic inequality by race and sex, with or without reference to labor market structures, has been done using models and methods developed for the analysis of achievement in cross-section, rather than for the analysis of careers. The purpose of this paper is to contribute to the small body of empirical research on career dynamics. Following Sørensen (1975; 1977), careers are defined as levels of status and wages individuals attain over their work lives and are modeled using a simple linear differential equation.[1]

In the next section, the literature on labor markets is used to develop hypotheses that are to be tested in this paper about sex and race differences in careers. Following this, the model of career trajectories is explained. The career model is then estimated by pooling of cross-sections and time-series methods, using data from the National Longitudinal Surveys of Labor Market Experience of Young Men and Young Women. The results of this estimation are discussed, and conclusions drawn, in the final sections.

SEX, RACE, LABOR MARKETS, AND CAREERS: HYPOTHESES

Careers take place over time. They have beginnings, from which people, on

An earlier version of this paper was presented at the Annual Meeting of the American Sociological Association, Boston, Mass., August, 1979. This research was supported in part by Canada Council grant 410-77-0530 and by National Institute for Mental Health grant 5-T32 MH 15163-02. I am grateful to Edward Withers, Carol Welch, and F. Yvonne McDonald for their assistance with the data analysis and to François Nielsen, Dennis Hogan, and anonymous reviewers for their helpful comments.

[1] This definition of careers is similar to that used by Form and Miller (1949) and Lipset and Bendix (1952) and is more general than definitions of careers as a succession of related jobs in a hierarchy of prestige through which one moves in an ordered, predictable sequence (Wilensky, 1960) or as jobs within a particular firm (Rosenbaum, 1979; Halaby, 1979). See Spilerman (1977) for an extended discussion of the term "career."

the average, move up.[2] Between the time of their entry into the work force and of their retirement or withdrawal from it, people's income, status, and other rewards change. This change takes place with a certain speed, which may vary across groups with different characteristics and in different types of labor markets. People with given characteristics in given labor markets will, as they live their work lives, approach some highest possible career level—or potential—which they may or may not actually reach, depending on the speed of their mobility.

This process is perhaps most easily grasped in the context of a career within a given firm. The firm has a job hierarchy. An individual entering the firm has credentials enabling him/her to qualify for some position or positions within the firm that, without a change in credentials, will be the highest to which he/she can aspire. To reach such a position usually requires time in the firm, as well as formal credentials. Some people formally qualified for a given position will actually reach that position, others will not. Those with different types of qualifications may have the same potential for a position but reach it with different speeds. For example, those with higher education may be able to go almost directly to their highest possible position while those without the credentials require some time to work their way up. (See Rosenbaum, 1979, for an analysis of such mobility within a firm.) Also, those equally qualified formally—but having different ascribed characteristics—may have access to different career lines and may take more, or less, time to advance. For example, Blau (1977) hypothesizes that, even within internal labor markets, women will have different kinds of career ladders open to them, and that, when those career-ladder positions are also held by men, women will advance more slowly up them than will men.

Although it is easy to visualize the career process by thinking of mobility within a firm, and, although some people do have such careers, average career profiles show the general pattern (of upward mobility approaching some potential) to emerge without the mobility being all within one firm (Sørensen, 1975; 1977). The hypotheses and model developed here refer to the average careers for men and women, by race, regardless of whether these take place totally within particular firms. The model developed in the next section enables us to look directly at (1) initial achievement, (2) factors affecting initial achievement, (3) potential achievement, (4) factors affecting potential achievement, and (5) the speed at which the potential is approached. Hypotheses about race and sex differences along these dimensions are also developed in this section.

Although this paper does not directly use the concept of dual labor markets or segmented economy to investigate differences in opportunity by race and sex, it takes the labor market and segmented economy literature as suggestive of the sorts of differences in opportunity by race and sex that might be behind differences in careers. Various typologies of labor markets and the economy have been offered: primary and secondary markets (Doeringer and Piore, 1971); male and female markets (Oppenheimer, 1970); monopoly, competitive, and state sectors of the economy (see development by Hodson, 1978); core and periphery sectors (Bluestone, 1970, used by Beck et al., 1978a; 1978b); open and closed employment relationships (Sørensen and Tuma, 1978). (See Kalleberg and Sørensen, 1979, for a review of the labor market literature.) Women and blacks have been found to be overrepresented in the secondary labor markets and in the competitive or periphery sector—that is, in those labor market positions that offer generally lower rewards and less chance for advancement (Hodson, 1978; Bibb and Form, 1977; Beck et al., 1978a; 1978b; Boyd and Humphreys, 1979). Further, within sectors and labor markets, there is additional sorting by sex and race (Hodson, 1978; Beck et al., 1978a), with the process of this sorting resembling the general sorting into labor markets (Blau, 1977; Dussault and Rose-Lizée, 1979). Thus, even within markets and sectors, women and blacks are often barred from high-reward, high-opportunity jobs.

---

[2] As Goldner (1965) has shown, not all career mobility is upward. In some managerial situations, downward mobility after a certain age is even considered the norm, as older people lose out in competition with younger. This can be treated as a change in the underlying career model, with a change from a growth to a decline model, or as a change in potential, the result of a change in the individual's characteristics. This will be discussed further in the context of the specific model to be estimated in this paper.

No one typology of labor markets or economic sectors will be able to capture the extent to which there are overall differences in opportunities by sex and race, given the sorting that also goes on *within* industries, occupations, and firms as well as between labor market divisions. This argues for continuing attention to studies of firms, as well as for continuing refinement of typologies of the ways in which labor markets are segmented. These activities are, however, beyond the scope of this paper. Here, instead, differences in careers by sex and race are predicted by using what has been theorized and discovered about the workings of opportunity structures by sex and race among and within markets.[3] I will argue that the estimated parameters of the career model can be used as social indicators of the general position of sex and race groups, summarizing the effects of between- and within-market sorting.[4]

Initial and Potential Levels of Job Rewards

As careers are viewed here, they have beginnings, at entry to the labor market, the levels of which are determined by the labor market in which persons are moving and their qualifications and background. They also have potential levels, which might or might not be reached, likewise determined by the labor market structure and the characteristics of the individuals. Most sex and race comparisons have been done cross-sectionally. Even when beginning job is treated separately, the average current job reward for any given group averages over those near the beginning of their careers, those approaching their potential, and those somewhere in between. When this is done, the differences among average job rewards for the different groups will depend on the career-stage composition of the groups as well as on the levels of rewards they receive at comparable career stages. This paper looks separately at the levels of job rewards at the beginning of the career, six years later (the last year in which observations were actually made, as will be discussed in the next section), and at the potential. Discussions in the labor market literature and existing over-time comparisons suggest several hypotheses about initial and potential wage and status differences, by race and sex.

(1) All women and nonwhite men will have lower average initial and potential wages. Given the wage structure evidenced in core versus periphery or primary versus secondary markets, and the overrepresentation of women and minority members in just those markets offering lower rewards and less opportunity to advance, plus the nature of sorting by sex and race within markets, I expect all women and nonwhite men to start their careers at a disadvantage (as Gordon, 1972:115 suggests), and to have lower potential wage levels than white men.

(2) The gap in average wages between white men and other groups will increase over the work life. Hoffman (1978) discusses the increase in wage differences between black and white males over the life cycle. Nonwhite men (and women generally) might be denied access to jobs

---

[3] Four groups are being compared here: white men, white women, nonwhite men, and nonwhite women. Most of the nonwhites are black. Much of the prediction will involve a contrast between two groupings of these four categories—for example, what is expected for white men on the one hand, and for nonwhite men, white women, and nonwhite women on the other. Although some work has been done that examines race and sex simultaneously, it is still difficult to find the basis for ordering all four groups with respect to each dimension of careers. This ordering is the end product of the empirical analysis in this paper.

[4] One would expect that the type of socioeconomic reward used to define the job level over time would affect the comparisons made of careers. Socioeconomic status changes only with occupation (and such change is a necessary—but not a sufficient—condition for change in status). Income, in contrast, can change without a change in occupation, as typically measured by three-digit census codes. Admittedly, both measures are rough. The use of socioeconomic status and income together, however, may be suggestive of the ways in which careers are structured, in general, for different groups.

that motivate and provide training and advancement and, thus, the chance for higher wages; and so they fall farther and farther behind white men. It is to be expected, then, that the wage differences between white men and other race/sex groups would be greater at their potentials than initially, and that the distance between starting and ending (or potential) wages would be greater for white men than for other groups.

(3) The average status of nonwhite men will be lower initially and at their potential than status of white men, although the average status of white women will be about the same as that of white men at their potential and perhaps even slightly higher at career entry. Given the sorting into occupations, by race, that occurs within and between markets and sectors, I would expect the status of jobs held at any career stage by nonwhite men to be, on the average, lower than that of jobs held by white men. For women, especially white women, this sorting into occupations on the basis of sex has been found, in cross-section, to lead to jobs with average status about the same as that for men, as women are concentrated in lower white-collar jobs which have fairly high status (although low wages). (See Oppenheimer, 1970; Treiman and Terrell, 1975; see also Nilson, 1976, and Bose, 1973, for discussion of the determination of prestige by sex.) Although nonwhite women have been found more often in service jobs—with both low status and low pay—than in clerical jobs, recently there have been shifts of nonwhite women into the traditionally female positions (Jusenius, 1975; Allen, 1979). For young nonwhite women, average status profiles are expected to be somewhere between white women's and nonwhite men's, because they will represent a mix of lower white-collar, service, and blue-collar jobs.

(4) The status distance to be covered, on average, by white men will be greater than that covered by women or nonwhite men. Women and nonwhite men tend to be in those jobs with restricted opportunity to move up. Workers in such jobs are not expected to remain with the job, are not given much on-the-job training, and perhaps do interrupt their employment; thus, they remain at roughly the same occupational level. White men are supposed to be especially likely to be operating in internal labor markets, where one enters a firm at a particular entry port and continues up the career ladder within the firm, protected to a large extent from competition with outsiders (Doeringer and Piore, 1971). I would expect such men to have a greater potential distance to cover than those without such career ladders. Further, Blau (1977) has found that even when women are in internal markets the career ladders in which they predominate tend to be flatter than those for men. Generalizing to all groups sorted into disadvantageous labor market positions, women and nonwhite men are expected to have less actual and potential status mobility than white men. Empirical evidence on the status distance between first and current jobs, by sex and race, is consistent with this hypothesis (see Duncan et al., 1972; Rosenfeld, 1978; Wolf, 1976; Sewell et al., 1977).

Return to Resources

Of course, differences in status and income levels could be due to differences in the characteristics of different groups rather than to segregation in a particular type of labor market and sector. Indeed, those in secondary labor markets and in the competitive sector have been characterized by (and found to have) lower educational and skill levels (Beck et al., 1978b; Hodson, 1978; Doeringer and Piore, 1971; Gordon, 1972; Boyd and Humphreys, 1979). One needs to know, then, about the *returns* to various work-related resources across groups. If returns are the same across groups, then differences in level of achievement would be the result simply of differences in levels of resources (although the chances or motivation to get additional training, education, and so forth, could also be influenced by labor market location).

Also of interest is whether supposedly nonwork-related characteristics are evaluated differently for different groups. The overrepresentation of women and nonwhite men in the less desirable labor market positions has been explained, in part, by the idea of "statistical discrimination," whereby the core or primary market employers reduce their risk of hiring unstable or untrainable employees by using easily visible characteristics—such as race and sex—as screening devices. Any one individual with these traits will not necessarily be a bad risk, but, on the average at least, some employers believe that these group members will be less desirable employees (Phelps, 1972; Thurow, 1975). Spence (1974) has shown how this sort of screening can pay off for the employer even when the trait used to screen is *not* related to productivity. The analysis here is conducted separately, by race and sex groups, to capture such effects of screening on these traits. There may, however, be other easily observed traits, such as marital status, that are used to further channel people into more or less desirable positions. This screening can appear as differences in the effects of these traits for those assumed to be in different positions within the labor market if the screening works differently in different labor markets.

With respect to returns to resources and other traits, I suggest the following hypotheses.

(1) The wage returns to education, training, and other resources will be lower for women and nonwhite men than for white men. The returns to resources are expected to increase over the work life for white men, but not for other groups. The training and skill of workers are important in the more desirable labor market positions. People may be selected into the primary market and competitive sector on the basis of their credentials. Higher returns to education, then, would show up as a result of this selection. Thurow and Lucas (1972) suggest that education inversely represents to the employer the firm's cost in training a worker rather than the ability of a worker to perform a certain job. If this is the case, then the returns to education should increase for those who are in careers where training occurs and promotion is possible—that is, for white men especially. Further, Beck et al. (1978a) have suggested that, for minority group members in the better parts of the labor market, credentials are evaluated differentially, as the employer's protection against making a mistake in hiring (because it is more difficult and costly to fire a mistake in these sectors than in the secondary or periphery areas). Women and nonwhite men would have to be overqualified to get the same positions as white men and, thus, have lower returns to their resources. This might be especially true for blacks, the quality of whose education might be doubtful in the mind of the employers. Beck et al. (1978a) show that minority workers (nonwhite men and both nonwhite and white women) received lower earnings in relation to their education and experience than did white men, especially within the core sector. Bibb and Form (1977) also found differences between blue-collar women and men in wage returns to their education and tenure, even after roughly controlling for sector.

(2) The differences between white men and women, generally, in returns to resources will be less when career position is measured by status than when it is measured by wages. Gordon (1972:117) has said:

> One would expect more evident patterns of returns to education among women, both because stronger discriminatory patterns against women within the labor market help reduce the bargaining strength of women (and permit employers to reward the more educated without fearing for greater mobility), and because many women work in a variety of white-collar clerical jobs for which some general educational skills are useful.

This statement might be more relevant with respect to status than with respect to wages, however. Treiman and Terrell (1975), Featherman and Hauser (1976), and Sewell et al. (1977) provide evidence of greater similarity between women and men in status returns than in wage returns to education and other resources. Some increase over the career in status returns to resources is still expected for white men but not for white or nonwhite women, given the restrictions on women's opportunity.

(3) Marital status and number of children will be used as additional screening traits for men but not for women. Being married and having children will increase

status and wages for men, but will have no effect for women. Although, in principle, family of procreation characteristics are not related to productivity, they may be used as indicators of stability by employers. If this is true, there should be effects of marital status and number of children for men but not for women in the analysis of this paper, which uses data from samples of workers continuously employed. Although some have argued that because—for women—being married and having children constrain both employment and career advancement, there is evidence that these variables are primarily proxies for employment history, with effects on career gains that tend to disappear when extent of employment is explicitly included in a model of status mobility (Rosenfeld, 1978; Boyd, 1977). Controlling for employment, marital status, and number of children would not be of much use to an employer in screening women from jobs with long career ladders. If a woman *is* married, she may be seen as lacking commitment to the labor force; if she is not married (or is married and does not have children), she may be seen as unstable because she *will get* married or *will have* children.

For men, in contrast, having a family may represent both the incentive to go after higher income and status and the signal to an employer that a man is going to be a good employee. This is probably true especially for young white men, just beginning their careers, who potentially have access to jobs with longer career ladders and who cannot use their past employment records as evidence of their stability. The drop in youth unemployment with marriage for young men is one basis for suspecting that marital status for men is, indeed, related to employment patterns. The results in Duncan et al. (1972, chap. 8) are consistent with the hypothesis.

Tests of hypotheses about the levels of status and wages, by race and sex, and about returns to various resources, have been carried out in research from both the status-attainment and the labor-market/economic-sector perspectives. The career model adds to this research primarily by focusing attention on both initial and potential levels of attainment. In cross-section, one cannot be sure at what stage careers are being observed. The attainments of various groups and the effects of independent variables on these attainments will depend on the stage of the process for the different groups. Careers are dynamic—they occur over time—and this dynamism affects even their "static" component.

Speed of Achievement

Perhaps even more important than correct estimation of these cross-sectional aspects of careers is the ability to estimate, directly, the dynamic aspect with this model. That is, one can estimate the speed with which the distance between initial and potential attainments is covered.

Assuming that white men are overrepresented in labor market positions that offer the greatest job mobility opportunities, I hypothesize that:

White men will reach their potential earning more slowly than other groups, but they may reach their potential status more quickly. White men would be expected to reach their maximum earnings more slowly than other groups because of the greater number of rungs on their career ladders (Sørensen, 1977). Essentially, their peak earnings would occur later in their work lives. Women and nonwhite men would be expected to reach their maximum earning ceilings more quickly. White men are thus expected to have greater opportunity for earnings *mobility* over their work life, while other groups are expected to have greater opportunity to *reach* their potential. Oppenheimer's (1974) discussion of career profile differences is consistent with this hypothesis. Looking at age differences in earnings of white men within occupational categories defined by level of peak earnings, she reports that, although young men (18 to 24) tend to be similar in their levels of income regardless of occupational category, their patterns of earnings, by age, differ considerably by occupation—with two general patterns emerging: Earnings for men in most blue-collar and middle- and low-level white-collar occupations peak early, before age 45; but high-level professional, managerial, and sales occupations seem to peak later, after age 45. The late-peaking occupations are those in which white men are most likely to be represented, and from which both women and nonwhite men are likely to be excluded.

For socioeconomic status, the predictions about relative ordering are reversed. Status is a relatively rough measure of level of job. Males entering internal labor markets might be expected to obtain, rather quickly, the highest occupational category they will obtain. Women and black men, who are restricted in the career ladders to which they can gain access, might have some possibility of upward mobility in status, but only after "proving" themselves by extended occupancy in a stereotypic occupation. In this case, they would slowly reach their potential status. If, however, there were no possibility at all of moving up from a typically black or female job (which most often would be in the secondary labor market and/or competitive sector), then it could be that women and blacks would reach their maximum statuses even more quickly than white men.

In summary, I expect to find that: women generally and nonwhite men have lower average initial and potential levels of income and at least nonwhite women and nonwhite men have lower average initial and potential status levels than white men; on average, the status and wage distance to be covered by nonwhite men and by all women will be shorter than that to be covered by white men; education and other resources should give fewer returns in the form of initial and potential levels of income and status to all women and to nonwhite men than to white men, while men (perhaps, particularly, white men) will benefit from having their own families, especially early in their careers; and the speed at which the maximum earnings level is attained will be slower for white men than for other groups, while the relative speed with which maximum status is reached will possibly be slower for women generally and for nonwhite men.

The Career Model

Careers have been described in the previous section as the process whereby people move up in status or in wages, over their work lives, to approach some potentially highest position. A fairly simple model of this sort of process is a partial adjustment model (see, for example, Doreian and Hummon, 1974; 1976):

$$dY/dt = -b\,(Y^* - Y). \qquad (1)$$

Here, Y is either status or income achieved, and Y^* is the potential level of status or income. The rate of change in Y (dY/dt) is proportional (by $-b$, which is positive because, here, $b<0$, as explained below) to the gap that exists between the achieved level of Y and the potential level. If the potential is reached, then change in status or income will cease.[5]

The criterion Y^* could be set in any of a number of ways. Here, it is assumed that the criterion will be a linear function of the individual's characteristics—both job-relevant and others—with the weights associated with the characteristics varying according to the labor market position of the group to which the person belongs:

$$Y^* = a_0 + a_1X_1 + \ldots + a_KX_K \qquad (2)$$

where there are K individual characteristics. This definition of the potential is consistent with the work that has been done to date from both the status attainment and labor market perspectives.

---

[5] I wish to thank an anonymous reviewer for pointing out that the explanation of the model and of the results would be simpler if I explicitly used the partial adjustment form. An earlier version of this paper presented the model as the "negative feedback" model, which Coleman (1968) describes and Sørensen (1975; 1977) uses. The "negative feedback" model specifies the rate of change in Y as a linear function of the level of Y itself and of the values of exogenous variables. The two models are mathematically the same when the criterion Y^* is completely determined by the exogenous variables (ignoring for the moment the problems of misspecification and measurement error). See Rosenfeld and Nielsen (1978), Rosenfeld (1979), and Hannan and Tuma (1979) for a discussion of the two approaches.

Substituting the right side of Equation 2 for Y* in Equation 1, and multiplying Equation 1 through, gives a simple linear differential equation, which is easily solved (Coleman, 1968) to yield an equation defining the career trajectory—that is, the levels of Y over time:

$$Y_t = e^{bt}Y_0 + a_0\,(1-e^{bt}) + a_1\,(1-e^{bt})\,X_1 + \ldots + a_K\,(1-e^{bt})\,X_K\,, \qquad (3)$$

where Y_0 is initial income or status.

The potential Y* as defined here need not be some fixed level. It can change in response to changes in individual characteristics. In socioeconomic achievement terms, this would mean that people could continue to improve their potential position by increasing job-relevant or other resources or could suffer a decrease in ultimate achievement because of depreciation of a resource or an increase in a liability. If, for the sake of simplicity, one assumes that the change in some individual characteristics is linear and occurs independently of changes in job rewards, then allowing for such change is straightforward (see Coleman, 1968, for the general form). If, say, X_1 were to change linearly and independently of Y, then the solution to Equation 1, when the criterion Y* is defined as in Equation 2, would be:

$$\begin{aligned} Y_t &= e^{bt}Y_0 + a_0\,(1-e^{bt}) + a_1\,(1-e^{bt})X_1 \\ &\quad + a_1 \left\{\frac{1-e^{bt}}{bt} - 1\right\} \Delta X_1 + \ldots \\ &\quad + a_K\,(1-e^{bt})\,X_K \qquad (4) \end{aligned}$$

Including the change term does not change the relationship among the other parameters of the model, but adds extra information about the model and its fit (Coleman, 1968:441–3).

As it is stated here, the model has face validity in that, when b is less than 0 and entry level is less than potential level, it predicts a career trajectory that is like that observed, at least for men: one in which there is rapid increase in reward levels early in the career and then a levelling-off (Ornstein and Rossi, 1970; Sørensen, 1975; Rosenfeld, 1978).[6] The speed with which the distance between some entry level and the potential level is covered is indicated by b: the larger b is in absolute value, the more quickly the gap between achieved and potential level is reduced. One could say that groups with a higher absolute value of b have a greater opportunity to reach their potential, while groups with lower absolute values of b have greater opportunities to be mobile (see Rosenfeld and Nielsen, 1978; Rosenfeld, 1979).

To complete the model, one can add an explicit formulation of the way in which individual characteristics determine Y_0:

$$Y_0 = c_0 + c_1\,X_1 \ldots + c_K\,X_K. \qquad (5)$$

The individual characteristics determining the initial reward levels need not be the same as those determining the potential.

The assumption that changes in individual characteristics occur independently of changes in reward level is made for simplicity, and is probably not a realistic assumption. Ideally, one would simultaneously model changes in employment, in rewards received for employment, and in resources and family circumstances. Some attempts have been made in this direction (Doreian and Hummon, 1974; Tachibanaki, 1979), but there is still need for more thought about the conceptual and methodological problems involved in such models. The model presented in this paper is, thus, a first approximation of a dynamic model of careers, valuable in demonstrating the need for attention to the time component of careers and the further steps such attention should take. (See Blalock, 1969; Coleman, 1968; and Hannan and Tuma, 1979, for discussion of multiequation models.) In this paper, after a description of the data and estimation techniques, the model represented by Equations 1 and 5 will be estimated and the various components of the careers will be compared by sex and race.

---

[6] The condition $b < 0$ is necessary because, if b were greater than 0, the trajectory would move from this maximum level at an accelerating rate, which does not make sense substantively. As will be seen later, the income and status trajectories of the sample studied here are like those predicted by Equation 3 or 4 with b less than 0 and initial position less than the maximum.

DATA AND METHOD

The data with which to test the hypotheses about sex and race differences in career dynamics are from the National Longitudinal Surveys of Labor Market Experience (NLS) of Young Women (1968–1975) and of Young Men (1966–1973). The samples were chosen to represent the civilian noninstitutionalized population of the United States aged 14 to 24 at the time of the first survey for each group. Each sample initially included approximately 5,000 individuals, of whom approximately 1,500 were nonwhite. Detailed employment and educational histories were collected over the years of the surveys (which are still in progress). Such longitudinal data are essential if dynamic models are to be estimated. (See the National Longitudinal Surveys Handbook, CHRR, 1979, for further details.)

From each sample, only those who were still employed at the time of every survey date after the first (1967, 1968, 1969, 1970, 1971, and 1973 for the young men; 1969, 1970, 1971, 1972, 1973, and 1975 for the young women) were included in the analysis so that the greatest number of observations could be used in pooling of cross-sections and time-series to estimate the parameters of the model.

This selection of cases implies potential bias. The young women selected are likely to have a greater commitment to the labor market than other young women of comparable age. They are, therefore, more likely to be the ones who have "careers" in the sense of longer career ladders. (See Rosenfeld, 1977, for a comparison of women with and without employment breaks, using data on an older NLS cohort.) To the extent that this is true, differences between the women and men will be attenuated. Although this selection procedure is the result of the conceptual difficulties in measuring the socioeconomic attainments of women not in the labor force, it might be seen as a response to the argument that the reason women have flatter career profiles than men is that they spend less time in, and are less committed to, the workplace.[7] If there are still sex differences now, it will probably not be because of lesser employment experience for the women.

The selection affects the young men in that those in the military during this period (which covers the height of the Vietnam war) are excluded. During the Vietnam era, those with higher educational attainments were less likely to serve, as were those with lower ability and poor health. Black high school graduates, who might be seen as those blacks most likely to be successful in the labor market, were disproportionately likely to serve during the Vietnam period, but, relative to whites, blacks reporting health limitations were also more likely to serve (see Shields, 1977). To some extent, then, whites with better career chances and blacks with poorer career chances might be included. However, given the nature of occupational deferments, the white men in the sample might have made career choices different from those of a cohort entering the labor market during a period of relatively low exposure to the draft. For example, more college-educated young men might have entered teaching than would have, ordinarily. Given sex differences in careers, however, these men might still have an advantage over women in their chances for promotion. Further, counterbalancing the selection of nonwhite men with worse career chances is the selection of those with continuous employment in the face of very high unemployment rates for young black men relative to other groups (Winship and Rosenfeld, 1979).

Comparing the 1970 characteristics of members of the NLS who were employed all years with the 1970 Census description of people having the same sex, race, and age ranges shows the sort of bias in the subsample: members of the subsample of the NLS providing data for the analysis of this paper are more likely than the general population to have gone to college, given that they have at least a high school diploma; the men in the sample are more likely—and the women (especially the nonwhite women), less likely—to be married than the comparable United States population; while both men and women in the subsample are less likely to be doing service work, the women are also somewhat more likely than the general female population to be professionals, clericals, or operatives, and though the men are less likely to be clericals they are more likely to be managers (if they are white) or farm workers (if they are nonwhite) (U.S. Bureau of the Census, 1970).

---

[7] However, Fligstein and Wolf's (1978) results suggest that the *effects* of resources on attainment are not severely biased by selection of currently employed women.

Careers will be indexed by two variables: by socioeconomic status (SEI, see Duncan, 1961) and by hourly earnings on main job (in 1972 cents, with wages adjusted using personal consumption expenditures implicit price deflators in the Economic Report of the President, 1977). Three different sorts of individual-level characteristics will be used to predict the trajectories of SEI and wage: human capital variables, family of origin status, and family of procreation characteristics.

The first set of variables includes human capital variables, which influence an individual's productivity and/or the employer's perception of productivity. As already mentioned, the effects of such variables are expected to be greatest for those with jobs offering the greatest opportunities for advancement—that is, especially for white men. Education is one of the most important of these variables. Highest grade completed by the beginning of a two-year period (e.g., by 1967, 1969, and 1971, for the young men) is one measure of this. Change in this level over each two-year interval is also included. Formal training outside regular school is another way in which people can increase their human capital. Measures of whether training related to white-collar work (1 for professional, technical, clerical, sales, or general course outside regular school, 0 otherwise) or to blue-collar work (1 for skilled or other manual training, 0 otherwise) had been taken by the beginning of a two-year interval, and of whether or not there was additional training of either sort during the two years, were also included.[8] In addition to these measures of formal schooling and training, whether or not the individual reported that a health problem limited her/his extent or type of work (1 for some limitation, 0 for none) was included as a third measure of human capital. Health was assumed to remain relatively constant over an interval and was measured in about the middle of each two-year interval.

The second set of variables includes measures of socioeconomic background. Such factors have been a central concern of status attainment research, which endeavors to test the extent to which characteristics of one's family of origin, as compared with achievements of the individual, affect later achievements. Thinking in terms of intergenerational transmission of access to labor markets, one can imagine that a well-placed father could help a child get on a good career ladder by having knowledge of—and connections with—a firm, trade, or profession. If so, the positive effects of "good" family background would be expected to be especially strong for white men. Generally, though, effects of family background have been found to be largely mediated by education, which is included in the career model (Blau and Duncan, 1967; Duncan et al., 1972; Kelley, 1973; Sewell and Hauser, 1975; Sewell et al., (1977). The measures of family background included in the analysis to be presented here are SEI of father (or head of household) when the respondent was 14, mother's education (in years), and number of siblings reported in 1966 (men) or 1968 (women). All family background variables have values constant over time.[9]

The third set of variables is that of family of procreation characteristics. These include marital status and number of children (for women) or dependents (for men). (Marital status is coded 1 if the individual is currently married, 0 otherwise.) Marital status is assumed to have an effect which is constant over a two-year interval. Number of dependents (for men) and number of children (for women) are measured at the beginning of each interval. Change in the number of dependents or children over the two years is also measured. Responsibilities within the home are measured differently for men and women (dependents versus children) to capture differences in the ways such responsibilities may act on, or be imagined to act on, workers of different sexes.

---

[8] For the initial survey year (1966 for men, 1968 for women), all types of training taken outside regular school up to that date were reported. In each year after the first, however, respondents were asked about type of training taken *longest* in the time since the last survey. The rough measure formed from these questions may thus underestimate somewhat the proportion of persons with a given type of training.

[9] In more complete models of effects of family socioeconomic status, other variables, such as father's education and rural origin, are also included. These three variables were chosen to represent the range of effects family background has while minimizing problems of multicollinearity and missing data.

Means and standard deviations for these variables by sex and race are shown in Table 1.

As mentioned above, longitudinal data are necessary for any study of careers. One problem with the use of longitudinal data, however, is finding a methodology by which to take advantage of the amount of information available in them. To estimate the parameters needed to compare the speed of career development, the potential levels, and the effects of individual characteristics on this potential, one can estimate

$$Y_t = a_0^* + b^*Y_{t-1} + a_1^*X_1 \ldots + a_k^*X_k + e \quad (6)$$

(where some of the independent variables could be change variables) and transform these estimates to obtain the parameters in equations (1) and (2), for example, $\ln b^* = b$, $a_1^*/(1-b^*) = a_1$.[10] One could choose any two observation times within which to estimate these parameters, adjusting the estimates for the length of the interval. This, however, seems to waste information on the other periods for which one has income and status observations. Another solution is to pool the pairs of observations, so that the data from which the estimates are made consist of more than one set of observations for each individual. Using a two-year lag, there are three sets of years for each individual.

One can imagine estimating Equation 6 using ordinary least squares regression (OLS). However, lagged dependent variables often mean serious violations of the assumptions of OLS. If the model is misspecified (as is usually the case with predictions of individual socioeconomic achievement) and the excluded variables are relatively stable or systematically related over time, the error terms will include the effect of these excluded variables and will be correlated over time (autocorrelated)—that is, $E(e_te_t-1) \neq 0$. Further, the error term will be correlated with a regressor, since the lagged dependent variable at one time is the dependent variable another time. The OLS estimators will be both inefficient and inconsistent. The bias is especially great in the OLS estimator of the coefficient for the lagged dependent variable. Such bias can affect all the conclusions from the analysis, since b^* is not only of interest in its own right but also enters into the calculations of all the coefficients of the career model.

To reduce the problems of bias, one models the structure of the errors and then uses an estimating technique that takes into account the modeled error structure. The error term can be hypothesized to be as follows:

$$e = \mu_i + \tau_t + v_{it} \quad (7)$$

where the components are independently distributed with zero means and constant variances. The component for constant individual factors not included explicitly in the general model is μ_i; τ_t is the component for time effects; and v_{it} is the usual well-behaved random error term. Substantively, μ_i would represent unmeasured traits affecting achievement, such as intelligence, motivation, and energy, which differ across individuals but are relatively constant over time. τ_t represents unobserved variables that vary over time and in roughly the same way for all indi-

---

[10] As one anonymous reviewer correctly pointed out, given the interdependence of estimators—and, thus, estimates of speed of mobility (b), level of potential (Y*), and effect of traits on this potential (a)—it is not really possible to test independent hypotheses about all three dimensions of careers. I have done so here because of the conceptual independence of the components and because of the need to demonstrate how to interpret findings with respect to each.

[a] Training. White-collar training = 1 if professional, technical, clerical, sales training or general courses not leading to a degree have been taken by the date specified, 0 otherwise (see note 4 for further explanation). Additional white-collar training = 1 if any such training had been taken in a given two-year interval beyond that reported by the beginning of the interval, 0 otherwise. Blue-collar training = 1 if any skilled or other manual training has been taken by the specified date, 0 otherwise. Additional blue-collar training = 1 if such training has been taken over a two-year interval in addition to that reported at the beginning of the interval, 0 otherwise.

[b] Health limitation = 1 if respondent reported health as limiting extent or kind of work, 0 otherwise (see note 5 for further explanation).

[c] Marital status = 1 if presently married, 0 otherwise.

[d] Hourly wages: in constant 1972 cents.

viduals, such as the effects of the economy on socioeconomic achievement. With more than one observation per individual over more than one time, there is the possibility of estimating the various components of variance and controlling for them in estimating the other coefficients of the model.

An approach to estimation that takes the error structure into account is that of modified generalized least square (MGLS). This class of estimators is consistent and asymptotically efficient.[11] The small sample properties of GLS and MGLS have been examined by Hannan and Young (1977) (see also Hannan and Tuma, 1979). The particular MGLS estimator used in this paper is the one developed by Fuller and Battese (1974), which uses the fitting-of-constants method to estimate the covariance matrix (Henderson, 1952; Searle, 1971). This method is appropriate for this situation, in which some of the exogenous variables do not change over time. This algorithm has been included as part of the SAS computing package (Drummond and Gallant, 1977).[12]

RESULTS

Observed Career Profiles

Figures 1 and 2 show the observed career profiles (in solid lines) for white and nonwhite women and men. The data from which these profiles were drawn are in Table 1. The first time-point (1967 for young men, 1969 for young women) is the time of first job for many of these people and close to it for others, and will be discussed as approximately Y_0. Starting wages in 1972 cents vary as predicted: white men have the highest hourly wages, followed by nonwhite men, white women, and nonwhite women. The ordering of wages is first by sex and then, within sex, by race. The relative positions with respect to income remain the same six years later. Further, over the period observed, white men gain more in wages than nonwhite men, who in turn gain more than white women, who gain more than nonwhite women. The career profiles in Figure 1 show, however, that women and nonwhite men have very similar career profiles, while white men belong to a distinctly different pattern. Differences between white men and the other groups increase over the time observed. At the same time, the careers of men by race are parallel, and those of women by race are parallel.[13]

The story changes with respect to status. Here status is determined first by race and then, within race, by sex—but with women having the advantage. White women have the highest status profiles, nonwhite men the lowest; and white men and nonwhite women fall in between. Over the period observed, though, white men gain more in status than any other group, and nonwhite women gain the least (4.5 points), in line with what was expected.

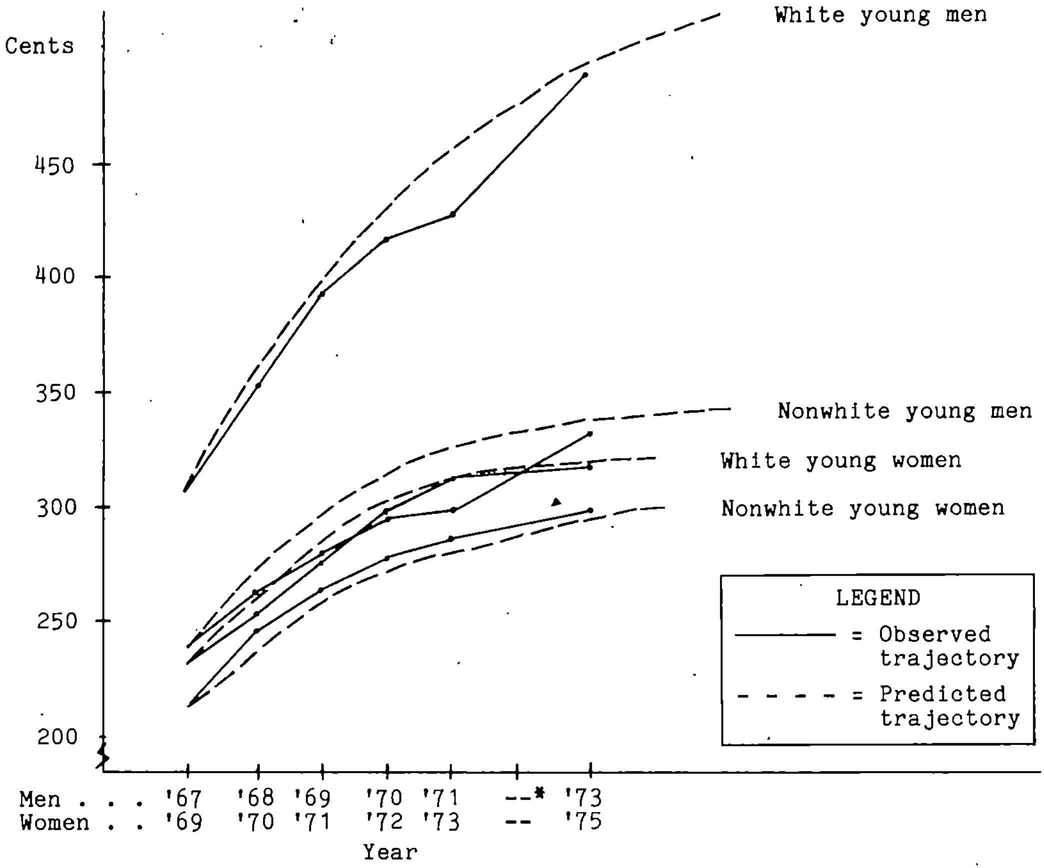
The differences in wage and status curves cannot be explained completely by sex and race differences in the levels of resources and constraints. Nonwhite men do have: a noticeably lower level of education and training (especially white-collar training); mothers with less education and fathers with lower status jobs; more siblings and dependents; and somewhat less stability as indicated by marriage. If all these variables affect achievement—and if these effects do not vary by race—we would expect lower achievement for nonwhite men on the basis of their personal characteristics. The case is not so clear for women, however. The women, here, are approximately as well educated as the men. They have higher rates of white-collar training, although less blue-collar training. White women, on the average, come from socioeconomic backgrounds

---

[11] Unfortunately, unlike maximum likelihood estimators, the parameter estimates obtained by MGLS do not necessarily retain their desirable properties under nonmonotonic transformations, such as those by which one calculates the parameters of the career mode.

[12] I wish to thank Andrew Kolsted for bringing this program to my attention.

[13] The abrupt rise between 1971 and 1973 for young men may reflect measurement error. The 1973 wage for young men was not calculated by CHRR, but had to be constructed by me for this analysis, using the reported CHRR procedures. Thus, this measure may be less clean than theirs.



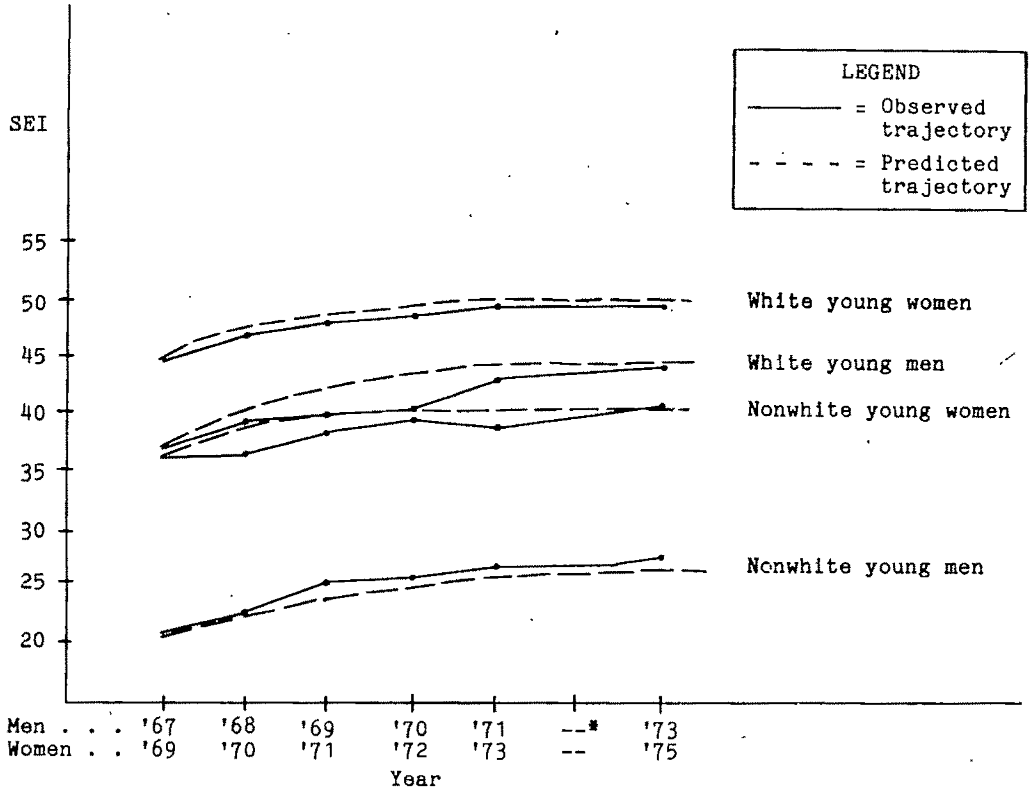
*No observation made this year.

Figure 1. Career Profiles by Sex and Race: Hourly Wages (in 1972 Cents) over Time for Those Employed 1967–1973 (Young Men) or 1969–1975 (Young Women)

similar to those of white men, while nonwhite women, like nonwhite men, come from families with lower levels of parental education and status and larger number of siblings (which, perhaps, makes their educational comparability with whites even more remarkable). The women, here, who have been employed fairly consistently over the six years observed, have lower rates of marriage than the men and have fewer children than do men, on the average, have dependents. This is true despite the tendency of women, in general, to marry at lower ages than men. They may, indeed, have chosen to commit themselves to work rather than to raising families, at least for a while. And, if anything, these women are healthier than the men, although only a very small proportion of any group reports health limitations.

Effects of Individual Characteristics: Initial Job

Returns to various resources, and constraints in early wages and status, are shown in Table 2. For all groups, education is important for early attainment. White men and women get approximately the same wage and status returns to their education at this stage of their work lives. Nonwhite women also receive returns comparable to those of white men—and much higher than those of nonwhite men. The location of these white and nonwhite women in lower white-collar jobs and of white men in positions where education, perhaps, is used to screen applicants, would seem to contrast with the position of nonwhite men who may be in exactly those positions for which education credentials are less important, as speculated



*No observation made this year.

Figure 2. Career Profiles by Sex and Race: SEI over Time for Those Employed 1967–1973 (Young Men) or 1969–1975 (Young Women)

before. Formal training is also of importance for the rewards received in early jobs. White-collar training increases the status of men and, to a lesser extent, of white women (some of whom have taken clerical courses within regular school). Blue-collar training also increases wages, significantly for all groups except nonwhite women. The effect is greatest for nonwhite men, for whom formal white- or blue-collar training perhaps is seen as a more reliable credential than education received in public schools of perceived dubious quality.

The returns to resources can be summarized by calculating returns to education and training using each group's coefficients and white men's average resources. If all groups had the average characteristics of white men, white men would receive the highest status returns to their resources, with white women and nonwhite women close behind. White men, with average white male education and training, would receive 65 status points on the basis of those resources. On the basis of their coefficients in Table 2 and the white men's means, white women would receive 61 points; nonwhite women, 57. Nonwhite men would receive the lowest returns to all their resources: only 35 status points.

With respect to wages, nonwhite men with average white male education and training are, still, the group with the lowest return to their resources: \$1.31/hour on the basis of education and training alone. White women actually receive the greatest return to their human capital at this career stage: \$3.02, compared with \$2.72 for nonwhite women and \$2.47 for white men.

Health limitations, which might be viewed as negative human capital, have no effects for men, but significant negative effects for white women. (See Corcoran

and Duncan, 1979, for a more detailed comparison of the human capital returns to men and women.) Nonwhite women have an unexpectedly positive return to health limitations. Since only 1 of the 86 nonwhite women has any health limitations, this probably reflects an idiosyncratic case.

As expected, effects of family of origin are largely mediated by education (as demonstrated also by regressions, not shown), with some small effects for nonwhite women and men. Family of procreation variables have effects primarily for men. For them, being married has a positive effect on both status and wages. For women, there is essentially no effect on marital status. For men at this career stage, it is possible that marriage represents either actual or perceived stability, while for women, as speculated before, the stereotype may be such that they cannot win. However, white women do receive some small positive returns to number of children, perhaps because this variable represents perceived stability and motivation to earn, as was hypothesized for men.

At this point in the work life, soon after entry into the work force, women and white men do at least equally well in returns to their human capital resources, while nonwhite men get the low returns predicted for those in secondary labor markets and in the periphery sector. Marriage is effective in demonstrating stability (or being associated with other positive traits) only for men.

The analysis so far has not used the dynamic career model to look at speed of achievement or to go beyond the observed data to the potential level of achievement. It only forms the basis for comparison with this potential and effects on it. We can now turn to results from the dynamic career model.

Estimated Potential Achievement

Table 3 presents the estimates for the difference equation in Equation 6, with error structure such as in Equation 7. In all cases, the individual specific component of the variance is relatively large. Ignoring this would lead to biased coefficients and would have resulted in misleading inferences, with a confounding of the b, an indicator of opportunity structure, with the effects of individual-level characteristics, such as motivation to search for a "good" job. The time-specific component, however, is relatively small. From these estimates, we can calculate estimates of the parameters of the differential equation model. The results of doing this are shown in Table 4.[14]

We can now go beyond the observed data to comparison of potential reward levels. Potential is calculated for each group as

$$a_0 + a_1 (\overline{X}_1) + a_2 (\overline{X}_2) + \ldots a_K (\overline{X}_K) \quad (8)$$

using estimated parameters a_i in Table 4 (derived from estimates in Table 3) and the last observed means for each group (generally from 1973 for the men and from 1975 for the women).[15]

At their potential, white women would, still, be expected to have the highest average status (50.3, compared with 44.8 for white men, 26.7 for nonwhite men, and

---

[14] With information on change in some of the exogenous variables, there are two ways in which coefficients for those variables could be calculated. One is the way used here. The second way is to use the more complicated formula in Coleman (1968), which utilizes information from the change variables as well. If the assumption of linear change in the exogenous variable is reasonable and if there is not too much measurement error, the estimates calculated in these two ways should give approximately the same result. As might be expected, although education seemed to vary linearly according to the tests in Coleman (1968), other variables did not. Since there is no compelling reason to seek another solution to the differential equation—because the overall result of including the possibility of exogenous change in X_i "leaves the original relationships between observations and coefficients of the model undisturbed" (Coleman, 1968:443)—the simpler formulation is used in Table 4.

[15] These estimates, as explained earlier, will change as members of the different groups increase their resources and liabilities. The qualitative implications will probably not change too much over time, however, as changes in education and training—two very important factors which determine potential—should occur at a decreasing rate, according to predictions of human capital theory and to empirical results. Marital status and number of children (dependents) may continue to change over a longer period of time. However, these factors are not large contributors to the potential level.

[a] Formulae used are: dynamic parameter = ln lag coefficient/Δt (where $\Delta t = 2$); potential coefficients = regression coefficient/(1 − lag coefficient). Lag and other regression coefficients are shown in Table 3.

41.4 for nonwhite women), having gained on the average a bit over 6 status points since their "first" jobs. This gain in status is in contrast to the lack of status gain found in data for women, generally (Rosenfeld, 1978; Wolf, 1976). This provides further evidence that to some extent women, in general, fail to gain in status over time because of discontinuities in their employment. When employed as are men, they do experience some gains. The white men have, however, gained slightly more than have the women (and the nonwhite men). Although their expected potential status is, still, lower than that of white women, it is now higher than that of nonwhite women. This probably reflects the greater heterogeneity in the jobs held by men over their work lives. As a group, they would show more mobility, as some white men get sorted into higher-level jobs over time in the work force. Nonwhite men, while experiencing a somewhat greater gain in status than nonwhite women, remain at the lowest status level.

The situation with respect to wages shows much greater contrast between white males and other groups than is true of status potential. At their potential level, white men would be expected to earn over $5.50 an hour, having experienced an increase in wages of over $2.50. Women and nonwhite men have gained, on the average, less than $1.00 in hourly earnings, receiving under $3.50 an hour in 1972 dollars. Nonwhite men continue to have average earnings somewhat higher than white women, who earn about $.15 more an hour than nonwhite women. This result suggests that lack of wage increase for women is *not* related to employment continuity.[16]

---

[16] Sandell and Shapiro, 1978, and Corcoran and Duncan, 1979, estimate that only 25% to 30% of the

Effects of Individual Characteristics: Potential Achievement

The coefficients (after the first line) in Table 4 represent estimates of the a_i, the effects of individual characteristics on potential achievement. At their potential, white men receive greater returns to their human capital than white women. They receive higher returns in terms of both status and wages to their years of formal schooling; get greater returns, in terms of status, to their white-collar training; suffer less of a status disadvantage from having some formal preparation for a blue-collar job; and receive considerably greater wage returns from both types of training but, especially, blue-collar training. The difference in returns to white-collar vs. blue-collar training is consistent with the idea of the rich plumber—that is, that many craftsmen and skilled manual laborers receive rather high pay for their valuable skills. While nonwhite men receive lower human capital returns than white men, they actually do better than white women, with the exception of somewhat lower wage returns to education. Nonwhite men, as compared with white men, continue to benefit in wages much more from white-collar training and less from blue-collar training and schooling, perhaps because of difficulty in having their educational certification (at least for secondary school) recognized as having any value, and because of difficulty in gaining access to jobs on which to use formal blue-collar training (which is perhaps the result of union control). Nonwhite women, the "double minority," receive higher status returns to their education than does any other group, and wage returns almost as high as those of white men. The returns they receive for formal training,.however, are as low as for white women. Poorly educated nonwhite women receive very low status, while well-educated nonwhite women (and, on the average, these women *do* have education beyond high school) have their credentials recognized. For them, education seems to be the key to high attainment. (The status returns on education for nonwhite women compared with other groups are consistent with Treiman and Terrell, 1975.)

Overall, if all groups had the 1973 resources of white men, white men and nonwhite women would receive the highest status returns (76.1 and 111.8) and white women and nonwhite men the lowest (46.7 and 48.7). With respect to wage returns, white men would gain the most ($4.28/hour) for having average education and training, followed by nonwhite women ($3.33), and then white women and nonwhite men ($2.57 and $2.44). In general, white men, who might be expected to have the greatest access to the better labor markets, receive the greatest returns from their educational and training credentials.

Family of origin effects are small but still evident at potential reward levels. If anything, they are somewhat stronger, here, when occupational differentiation is greater and sorting on the basis of family background might be more apparent, in contrast to the early career stage, when there is less differentiation. Having a large number of siblings, perhaps causing competition for attention and material support, negatively affects status and wage returns, significantly so in the status difference equation for both groups of men and white women. Having a higher-status father significantly, although very slightly, increases wages of white women and nonwhite men. Family of procreation variables, however, have almost no effect here, in contrast with the situation earlier in the career. Only in the status difference equation for white men does marital status reach significance.

This further confirms the idea that characteristics of family of procreation act primarily as screening signals for employers and that these are most important early in the careers of men, when on-the-job behavior is most in question.

In contrast with a time early in the work life, both white women and nonwhite men do worse than white men in the evaluations of their human capital. The change in the position of white women may be due to their more static occupational position. They remain in lower white-collar jobs that do not lead to positions giving greater

---

wage gap between white men and women can be accounted for by work history.

rewards to education and training credentials. As one can see from comparing Tables 2 and 4, the value of their credentials actually deteriorates slightly after they have entered the labor force. Nonwhite men, in contrast, do get increased returns to their education as compared with their early careers, as well as greater wage returns to their training, although the returns to their education remain relatively low. Nonwhite women, while not receiving returns to their formal training, get greater benefit from education at their potential than they did earlier in their careers, returns in some cases greater than those for white men. Of course, it must be kept in mind that the nonwhite women here are exceptions, in that they had jobs on each survey date. The small N for nonwhites, compared with those for whites, indicates the extent to which this is true. Beck et al. (1978a) found that nonwhite women received lower returns to human capital compared with white men, using an income indicator that took into account extent of unemployment. As emphasized before, this paper does not take race and sex as absolute indicators of labor market location. Some groups of women and nonwhite men will be more likely than others to be in the more desirable opportunity structures. Indeed, steady employment might be a sign of being in other than the secondary market. At the same time, one needs to keep in mind the values of the other components of the career model for nonwhite women. If nothing else, levels of wages for nonwhite women are below those of even nonwhite men.

With respect to the other types of variables included in the model, the findings are that family of origin has small effects that are, nonetheless, larger than those earlier in the career, perhaps because sorting into occupational levels was too far from complete for such effects to become apparent earlier. Family of procreation effects are smaller then earlier, perhaps because these variables are no longer needed to screen job applicants.

Speed of Achievement

Potential reward level, without changing resources and liabilities, is reached only as time reaches infinity—which is a longer time than anyone, to date, has spent in the labor force. The speed at which the potential is reached is, therefore, as important as the eventual level and is an indicator of the structure of opportunity. The first line for each sex in Table 4 gives estimates of the speed of mobility. Nonwhite women reach their status potential most quickly ($|b|$ of 1.073 is the greatest). White men and women attain their status potential at about the same speed ($|b| = .610$ and .604). Nonwhite men reach potential status most slowly, perhaps because of a possibility of advancement that is not always realized.[17] With respect to wages, white men, as predicted, reach their high potential most slowly, while white women reach their highest wages most quickly of all race/sex groups. For nonwhites, the ordering by sex is reversed.

The results concerning the speed with which the different groups reach their potentials in the two job rewards are consistent with what has been found by examining age differences in cross-section. In such examination, status potential is reached more quickly than wage potential. Occupation may stop changing while wages continue to change, even within the same occupation or general type of occupation. Otto and Haller (1979), although lacking good longitudinal data, show results suggesting that maximum status differentiation for men has been reached by age 35, while maximum income differentiation is not reached until about age 45.

In Figures 1 and 2, the estimated model is used to predict career trajectories, showing, in general, close fit to observed trajectories (the curves for nonwhite men's wages being an exception). The predicted values over time were estimated using

---

[17] Sørensen, 1979, argues that SEI is not a good metric with which to test such hypotheses because its distribution does not make sense as a distribution of socioeconomic reward. Transforming SEI in such a manner that he obtains an exponential distribution of attainment, he finds orderings, on b, of blacks and whites and of men and women that do not correspond exactly to the orderings obtained by using the usual SEI metric. I have not yet tried these models with his transformation, although I have such work in progress. One should keep in mind, however, that Sørensen used OLS, which means that his estimates are biased. As Table 3 shows, the extent of bias will differ across groups, making OLS comparisons suspect.

$$\hat{Y}_t = (e^{\widehat{bt}})\,\overline{Y}_0 + (1-e^{\widehat{bt}})\,\hat{Y}^*, \qquad (9)$$

where Y_0 = 1967 (for men) or 1969 (for women) status or wages, Y^* is the predicted potential shown in Table 4 and b is the "dynamic" coefficient in Table 4.

CONCLUSIONS

This paper analyzes career differences by race and sex, with careers defined as trajectories of socioeconomic status and income over the work life. It was assumed that the different groups tend to be in different labor markets and economic sectors and to experience different opportunities even within labor market segments, and this assumption guided predictions for (and interpretation of) results. The simple differential equation model describing careers allowed examination of various elements of inequality within the work force: entry level of status and wages; potential status and wage levels; effects of human capital, family of origin, and family of procreation variables on initial and potential reward levels; and the speed at which potential status and wages are approached. The dynamic nature of this model required longitudinal data and an estimation technique that could avoid the confounding of state dependence with unmeasured individual or time effects. The data from the National Longitudinal Survey of Labor Market Experience of Young Men and Women provided six years of work history for the analysis. These data were analyzed using a variance components model that controlled for unobserved variables constant over time for individuals and constant over individuals for each time. The results of this analysis showed the general advantage of white men in many aspects of careers, including wage levels and returns to human capital. Further, it showed the differences in effects of education and training, marital status, and parental socioeconomic status early in the career versus at the career stage when change has ceased to occur. The differences in speed with which equilibrium is reached for the two socioeconomic position variables and for the four groups give clues to the nature of the job structure through which men and women and blacks and whites move, over the course of their work lives.

The career model estimated here involves time, yet assumes some constancy. Basically, it assumes that once the trajectory begins it continues smoothly along as described by the equation. This seems not unreasonable. It may be that the economic conditions under which, and the particular position in which, one begins a career determines to a large extent where one goes from there. The small magnitude of the time-variance component is consistent with this speculation. With the longitudinal data currently and potentially available, however, one can look for period, cohort, and age effects. Using later panels from the group whose work histories were analyzed here, one could go on to see whether their careers in the next decade are as predicted by the model. Comparisons with the careers of young men and women beginning their work lives in the early 1980s (data on which will be gathered by a new National Longitudinal Survey of Labor Market Experience, and by High School and Beyond, 1980) might help answer the question of how the threat of the draft (as compared with the threat of a recession) affects career beginnings and trajectories. Comparisons of the effects of various economic shocks on different cohorts might suggest the nature of period effects vs. age effects. In general, then, the use of a simple career model such as the one estimated here enables one to use effectively the longitudinal data on labor market histories that have been and are being gathered to investigate change over and within lifetimes.

A model such as this provides an overview of careers: where a group came from, where it is going, and how fast it is getting there. As such, it is useful in giving us a variety of social indicators for the position of a given group. Understanding more fully what is behind the group differences, however, requires a closer examination of the nature of jobs held over time and of the types of job shifts occurring at the individual level. Further, to capture the extent of inequality in economic position, movement into and out of the work force must be analyzed. Although some of this work is in progress (see, for example, Winship and Rosenfeld, 1979), the interest in understanding the workings of labor markets and their effects on inequality has opened large areas of research problems that have not yet been addressed. This paper shows one—but only one—model and technique for analyzing the process of inequality.

CLASS AND INCOME INEQUALITY IN KOREA*

HAGEN KOO

American Sociological Review 1980, Vol. 45 (August):610–626

This paper seeks to contribute to recent efforts to improve status attainment models by introducing class categories or labor market segmentation. The research reported here replicates and extends Wright and Perrone's (1977) analysis of class categories and income inequality in the United States in the context of a rapidly industrializing society. The results confirm that Marxist class categories are as consequential as occupational status in explaining income inequality in both advanced and developing capitalist societies. Yet, there are several difficulties in applying this class model to developing economies, so that a substantially modified class model is developed taking the manual-nonmanual distinction and structural marginality as additional major axes of class determination. This new model is superior to Wright's (1976) model in explaining income inequality in Korea. In the final part of the paper, a tentative test of a dependency model of inequality is attempted, with negative results for the predicted hypothesis of the center-periphery sectoral inequality.

Class inequality is generally understood to be more crude and ominous in the early stage of capitalism than in its mature stage. With little organized power of labor and with little institutional protection, the exploitation of wage laborers by capitalists can assume its most naked character. At the same time it is also widely held that crystallization of class interests and clear demarcation of class boundaries in developing capitalism are severely limited by the remnants of precapitalistic elements and various distorting influences of the metropolitan economies in the world capitalist system. But beyond these broad expectations, little systematic knowledge has been advanced regarding the structure and processes of class inequality in peripheral capitalist societies. This paper seeks to fill a part of this vacuum with an empirical analysis of class inequality in one developing capitalist nation, South Korea.

In the present analysis, we take a point of departure from a recent study by Wright and Perrone (1977) of the relationships between class categories and income inequality in the United States. Wright and Perrone developed a reasonable operationalization of broadly Marxian class categories and demonstrated with multivariate quantitative analysis the significance of class positions in determining individuals' incomes in the States. We thought it would be useful to replicate their analysis with Korean sample data to see the similarities and divergencies in the class structures of the two societies. This analysis is presented in the first part of the paper.

But, as will be explained later, Wright and Perrone's model of class structure is not wholly satisfactory in the context of most peripheral capitalist societies. Thus, in the second part we develop a substantially modified class model and subject it to the same analysis. The results of both analyses are consistent with the American findings—that class positions are more consequential for income inequality than occupational status, and that class positions also have effects on the ways in which the individual's education influences his/her income. In the final section, we go beyond this status attainment framework and discuss some important issues raised by our data for the theory of class structure in peripheral capitalist societies.

An earlier version of this article was presented at the 1979 annual meeting of the American Sociological Association, Boston.

Wright's Class Model

Prior to his empirical analysis of class and income inequality in a coauthored article with Perrone (Wright and Perrone, 1977), Wright (1976) had advanced an operationalization of what he regarded as Marxian class categories. Following the unquestionably Marxian tradition, he first defined classes in terms of common structural positions within the social organization of production. He then proposed to define these structural positions in terms of three basic criteria: (1) ownership or nonownership of the means of production, (2) purchase or sale of the labor power, and (3) control or noncontrol of the labor power of other workers.

A combination of the first two criteria produces three major class categories which were identified by Marx himself: the capitalists, who own the means of production and purchase the labor power of others; the workers, who do not own the means of production and sell their labor power; and the petite bourgeoisie, who own the means of production but neither buy nor sell labor power.

Wright argues, however, that this orthodox conceptualization is not adequate in the advanced capitalist societies and requires some important extension. Most contemporary Marxist scholars agree on this point, although there is less agreement on how to modify it. Wright's claim is that in the contemporary capitalistic organization of production, control over the labor process constitutes a significant axis of the social division of labor. He insists that the managers who do not own the means of production but exercise control over the labor process occupy the "contradictory locations" torn between the bourgeois and the proletariat positions. It is more legitimate, he argues, to treat such contradictory positions as such, that is, as a distinct class position, rather than to include them arbitrarily in either the bourgeoisie or the proletariat. Thus, in effect Wright subdivides the larger worker class into the manager and the worker classes, according to the third criterion of control of the labor power of others. Wright's model can be schematically presented as shown in Table 1.

The Korean Economy

Before describing our data and variables for analysis, a few comments on the Korean economy may be useful. South Korea is widely known as an exemplary case of remarkable economic success through export-led industrialization. During 1963 to 1974, the real gross national product (GNP) more than trebled, growing at 10% per annum, and the per capita GNP reached an excess of $500 in current United States dollars in 1975 (Hasan, 1976; Westphal, 1978). Most observers agree that manufactured exports have been the engine of Korean economic growth. Statistics show that within a decade, from 1965 to 1975, the ratio of total exports to GNP more than trebled and the share of GNP originating in the manufacturing sector more than doubled. Manufactured products constituted 42% of total exports in 1965 and 75% in 1975 and the contribution of total exports to GNP rose from 12.9% in 1965 to 26.3% in 1975 (Westphal, 1978).

These spectacular economic changes have transformed Korea from a largely agricultural society into a semiindustrialized country in a relatively short time. Compared with other countries at similar levels of income and population, Korea maintains relatively high shares of manufacturing products to GNP and manufacturing employment, and its export

Table 1. Wright's Class Model

Class Categories	Ownership of the Means of Production	Purchase or Sale of the Labor Power	Control of the Labor Power of Others
Capitalists	Yes	Purchase	Yes
Managers	No	Sale	Yes
Workers	No	Sale	No
Petite Bourgeoisie	Yes	Self-Employed	No

shows the heavily industrial content. In 1975 the percentage share of manufactured products in GNP was 31.9%, while that of primary products was 23.0%; social overhead accounted for 13.7% and other services contributed 31.4%. In employment, 21.9% of the active labor force in 1976 was engaged in the secondary industry, 44.6% in the primary sector, and 33.5% in the service and commercial sector (Economic Planning Board, 1979). The official unemployment rate in 1976 was only 5.0%.

At the same time, Korea, like many other Third World countries, is heavily dependent upon foreign capital. Westphal (1978) notes that between 1960 and 1975 roughly 40% of total investment was financed from abroad. In the period from 1962 to 1966, Korea accepted 308 million dollars worth of foreign capital, primarily from Japan and the United States, of which 37.5% was in the form of public loans, 58.2% commercial loans, and 4.3% direct investment (Economic Planning Board, 1979). In the period from 1972 to 1976, this figure jumped to 5,989 million dollars with a noticeable increase in the proportion of direct investment (9.4%). According to the World Bank's report (1978), Korea's external public debt in 1976 was about 27.6% of GNP and the debt service ratio to GNP was 3.8%. According to these measures, external dependence of the Korean economy is higher than that of many other developing economies. But for a dependent economy, its performance in the past decade and a half have been really remarkable.

Data and Variables

The data analyzed in this paper were collected in the capital city of Seoul in the summer of 1976. Seoul is a typical example of a primate city; more than one-fifth of the nation's population (7.2 million residents in 1975) as well as the major political, economic, and educational institutions are concentrated in this city. If Seoul does not represent the whole nation, it certainly does constitute the most vital part of it. Its economy is fully industrial and capitalistic and it is in this economy that the profound economic changes in the nation have expressed themselves with least inhibition.

The survey data were gathered from a probability sample of male household heads, aged 21 to 65.[1] A sample of 900 household heads was originally drawn through the multistate random sampling method from the official Register of Residents, which provides a fairly complete list of residents. Due to recent moves and extended trips as well as some refusals, 795 interviews (88.3%) were completed by trained university students majoring in sociology and related social sciences. Of the 795 completed interviews, 21 were from respondents aged under 20 or over 65, and thus deviated from our sampling frame. Excluding these 21 cases, our usable sample includes 774 cases.

Variables

The main purpose of this analysis is to determine the effect of class categories on individual income, while controlling for the effects of education, occupational status, age and family background. Class categories are derived from the classification scheme described above. Ownership of the means of production is operationally defined by ownership of an independent enterprise. Accordingly, all the self-employed are treated as property owners.[2] Control of the labor power of other workers is measured on the basis of detailed job descriptions obtained through interviews and the number of employees in the work place. As in Wright's classification, teachers are excluded from the manager category and both manual and nonmanual workers are included in it. Purchase of labor power is a critical criterion that distinguishes capitalists from the petite bourgeoisie. In Korea, many small shopkeepers hire one or two assistants. Though nominally property owners and employers, their relations with hired workers are not typically capital-labor relations since these shopkeepers are immediate producers themselves, and their employees are usually their relatives. Thus, we decided to classify the employers of one or two workers in the category of the petite bourgeoisie.

---

[1] Women were not included in our sample because of budgetary constraint. This is unfortunate, because women's economic role and their class situations in industrializing societies are becoming more problematic from both a theoretical and an empirical point of view. Recently, Korean women have begun to participate in increasing numbers in marginal service occupations as well as in export industries as largely unskilled labor. Since women's wages are typically lower than men's, we conjecture that the inclusion of women in our sample would accentuate class differences between the capitalists and white-collar workers on the one hand, and blue-collar and marginal workers on the other.

[2] We will later point out that this is not a very satisfactory operationalization in less developed societies. Our interest in the present analysis is to follow Wright's operationalization as closely as possible for comparison of two societies at different stages of capitalistic development.

Education is measured by a 7-point credential scale rather than by years of education: (1) no or some elementary school; (2) completed elementary school (grade 6); (3) some secondary school; (4) completed secondary school (grade 12); (5) some college; (6) college degree; (7) post-college. Strictly speaking this is not an interval variable, although treating it as such would not violate common research practice in sociology nor does it affect any of our substantive conclusions. In the following analysis, we will use it primarily as an interval variable; but, when using discrete educational levels that may add new interpretations (particularly for examining class differentials in educational income returns), we use education as both a continuous and a categorical variable.

Income data were originally reported categorically (12 categories) and refer to the average monthly income derived from the respondent's occupation and occupation-related activities. For the purpose of this analysis we took the midpoint of the response interval as a point estimate of the respondent's income.[3] The Korean monetary unit is *won*, 485 *won* being equivalent to one U.S. dollar in 1976.

Occupational status is measured by applying Treiman's Standard International Occupational Prestige Scale (SIOPS) to 77 occupational categories (Treiman, 1977). Although the validity of this scale in the context of Korean society should be determined by a specifically designed nationwide survey, we attempted our own measure of validation. Specifically, we asked the respondent to compare the "social prestige" of 31 familiar occupational categories with his own occupation and rate them as "much higher," "similar," "lower," or "much lower." Later we assigned scores (5 to 1) to these categories and calculated the average score attributed to each occupation by these pair-wise comparisons. The product-moment correlation between Treiman's scores and our own scores is .75. Given this fairly high correlation, it should not matter too much which measure we use. However, there is no doubt that Treiman's international measure has more merits for a comparative study.

In the case of father's occupational status, we used only the first digit of Treiman's two-digit scores (e.g., 10 through 19 = 1) because more than a half of our respondents' fathers had farm occupations which show little occupational differentiation. In addition, farm-nonfarm categories of father's occupation are included in the analysis, partly to compensate for gross differentiation in father's status and partly to see the effects of this new sectoral dimension of social background (which overlaps closely with rural-urban background).

Age is also assumed to be related to income, not only as a proxy for years of work experience in the labor market but also as an important basis of reward allocation in this still heavily age-oriented Asian society.[4]

---

[3] It is notoriously difficult to obtain valid income data in most developing societies. We took special care to overcome this problem, by assuring our respondents that the information was confidential and stressing the importance of income information for this "worthy academic" research. We believe that our respondents gave fairly accurate information about their incomes received for their main or "formal" occupational activities but probably not about other incomes derived from their "informal" activities (such as money lending, property renting, commissions, or bribery). For this reason, we suspect that incomes of property owners and managers might have been underreported and, therefore, there is no compelling reason to employ log transformation of income data. Besides, using actual earnings makes interpretation more straightforward. In any event, our trial analysis with logged income variable produced essentially the same results as far as our hypotheses are concerned.

[4] Age shows a mild curvilinear relationship with income, as linear income increase tails off (but not

Table 2. Means and Standard Deviations (in Parenthesis) of Major Variables by Wright and Perrone's Class Categories

Class Categories	Income[a]	Education[b]	Age	Occupational Status	Father's Occupation	Farm Background	N
Capitalists	171,200 (87,940)	4.44 (1.54)	44.5 (9.5)	51.73 (10.60)	4.10 (1.02)	58%	104
Managers	168,090 (75,250)	5.16 (1.17)	40.8 (7.6)	57.38 (9.04)	4.45 (1.13)	48%	117
Petite Bourgeoisie	95,390 (60,350)	3.58 (1.35)	42.1 (9.6)	41.48 (10.78)	3.77 (.93)	63%	222
Workers	94,740 (55,330)	4.01 (1.57)	38.0 (8.2)	39.71 (15.43)	3.88 (1.04)	60%	236

[a] Income is expressed in Korean monetary unit, *won;* 485 *won* was equivalent to one U.S. dollar in 1976.
[b] Education is measured by a 7-point credential scale. See text for details.

Data Analysis

We will first compare the distribution of class categories in our sample with that in the American sample before examining the effect of class on income inequality. Table 2 shows the frequency distribution of four classes and the means and standard deviations of the variables for each class category.

The most remarkable difference between Wright and Perrone's samples and ours is the size of the petite bourgeoisie. In their American national nonfarm representative sample, the petite bourgeoisie constitutes only 4.3%, whereas in our sample it makes up 32.7%. Due to extremely small numbers, Wright and Perrone justifiably excluded the petit bourgeois category from their analysis. Obviously we cannot do the same, so our analysis will deal with all four categories.

The data also indicate that in spite of rapid industralization the proletarianization of the Korean urban labor force has not developed very far; only a little more than one-third (34.8%) of our sample belongs in the worker category. Interestingly, this is the case in the most industrailized part of Korea. In Wright's nonfarm sample, the workers constitute 49.2%.

About one-third of our sample is split between the capitalist and the manager classes. As in Wright and Perrone's sample, the capitalists in our sample are mostly small capitalists (71 of 104 employ fewer than 10 workers and another 22 employ 10 to 29 workers). About 15.3% of the sample falls in the capitalist category and 17.2% in the manager category; the comparable figures in the American sample are 7.4% and 37.4%. That the manager class is much smaller in Korea is easily understandable in view of a much smaller proportion of workers and the relatively smaller sizes of Korean industrial and commercial enterprises.

The income data in Table 2 reveal that the average monthly incomes of small capitalists and managers are almost identical (171,200 won or about $353 and 168,100 won or $347), while workers and the petite bourgeoisie are also quite similar in their incomes (94,700 won or $195 and 95,400 won or $197). To the extent that we can assume that income is a crucial component of class situations, this pattern of income distribution is a strong indication of a polar structure of Korean stratification. In regard to education, the managers seem to be the most highly educated (5.16 in our scale, which corresponds to some college education), while small capitalists are only slightly more educated (4.44) than workers (4.01). Educational attainment is lowest among the petite bourgeoisie (3.58). If we juxtapose the polar structure of income distribution with a smooth gradation of educational resources, we can find a clue to the independent role of the social organization of production in creating what we call class inequality beyond a simple stratification.

In order to test the first hypothesis concerning the independent effects of class

---

dramatically) after age 55. But since this curvilinearity is not strong and since only a very small proportion of our sample falls over age 55, we decided to use raw ages in all regression equations.

categories, we will employ dummy variable regression analysis, using the following equation:

$$\begin{aligned} \text{Income} = {} & a + b_1\text{Education} + b_2\text{Age} \\ & + b_3\text{Father's Occ.} \\ & + b_4\text{Occ. Status} \\ & + b_5\text{Capitalist} + b_6\text{Manager} \\ & + b_7\text{Petite Bourg.} \end{aligned} \tag{1}$$

The results of the analysis presented in Table 3 show that even if we hold education and other causal components of income constant, employers are likely to receive about 47,000 won more, and managers 31,000 won more, than workers. These differences are statistically significant (regression coefficients being greater than twice their standard errors). The difference between workers and the petite bourgeoisie, however, is both statistically and substantively insignificant. A test for the overall significance of the class dummy variables considered as a whole (by comparing the explained variance before and after the dummies are added, and computing an F-test with 3 and 676 degrees of freedom) reveals that class effect on income is significant at .001 level of significance.

But a better way to weigh the effect of class variable is to compare it with the effect of occupational status. Wright and Perrone's analysis showed that class has a stronger effect than occupational status. For this comparison, we try to determine whether the regression equation which includes class variables (Equation 2) explains a larger proportion of variance in income than does Equation 3 which includes occupational status.

$$\begin{aligned} \text{Income} = {} & a + b_1\text{Education} + b_2\text{Age} \\ & + b_3\text{Father's Occ.} \\ & + b_4\text{Capitalist} + b_5\text{Manager} \\ & + b_6\text{Petite Bourg.} \end{aligned} \tag{2}$$

$$\begin{aligned} \text{Income} = {} & a + b_1\text{Education} + b_2\text{Age} \\ & + b_3\text{Father's Occ.} \\ & + b_4\text{Occ. Status} \end{aligned} \tag{3}$$

Table 3 shows that Equation 2 explains 46.9% of the variance in income, while Equation 3 explains 43.3%. From a different view, when class is added to the equation containing occupational status, the total explained variance increases by 5.0% (48.3 − 43.3), whereas when status is added to the equation containing class, the increase is only 1.4% (48.3 − 46.9). An obvious conclusion asserts itself: class has a greater explanatory power than occupational status in predicting income. Thus, the first hypothesis is confirmed by our data.

The second hypothesis suggests that class position affects the relationship between education and income, producing different income returns to education for different social classes. In statistical terms, this hypothesis predicts that education slopes are not constant but vary significantly according to class categories. In order to test this hypothesis, we will compare four class categories for the following two regression equations.

$$\text{Income} = a + b_1\text{Education} \tag{4}$$

$$\begin{aligned} \text{Income} = {} & a + b_1\text{Education} + b_2\text{Age} \\ & + b_3\text{Father's Occ.} \end{aligned} \tag{5}$$

The findings presented in Table 4 show that income returns to education are high-

Table 3. Regressions of Income on Wright and Perrone's Class Categories and Other Causal Factors of Income (Standardized Regression Coefficients Are in Parentheses)

	Dependent Variable = Income

Difference in Education Coefficients	3,920	3,910	5,240	8,110	3,860	6,630	7,790	10,540
t-Value Difference	1.2	1.2	1.5	2.2*	1.6	2.6**	2.0*	2.5**

* Significant at .05 level with one-tail significance test.

** Significant at .01 level with one-tail significance test.

est among managers and lowest among the petite bourgeoisie. Considering the simple regression of income on education (Eq. 4), managers as a whole earn 27,800 won for each increment in education, compared with 18,700 for the petite bourgeoisie; comparable income returns for small capitalists are 26,480 won and 22,560 won for workers. According to t-test results, the differences between the petite bourgeoisie and managers or small capitalists are statistically significant at the .05 significance level, whereas the difference between workers and any other class category is not significant.

The pattern of differentials between classes remains the same when we hold age and family background constant, but the gaps tend to widen. Again income returns to education are highest among managers; for each increment in education, they tend to receive 4,200 won more than small capitalists, 8,110 won more than workers, and as much as 14,740 won more than the petite bourgeoisie. The latter two differences are statistically significant at the .05 level. While small capitalists receive 3,910 won more than workers for each level of education, the difference is not statistically significant, whereas the difference of 6,630 won between workers and the petite bourgeoisie is statistically significant. There is also a marked difference (10,540 won) between small capitalists and shopkeepers, which is statistically significant.[5]

That managers rather than capitalists receive the highest income returns to education in Seoul disagrees with the reverse pattern found in Wright and Perrone's American sample. But our finding makes more sense because employers are not paid wages in relation to education but, rather, pay themselves out of their profits. The same logic applies to the higher return among workers than among the petite bourgeoisie.

---

[5] The significance of the education slope differences between class categories is assessed by the following t-test:

$$t = \frac{b_{11} - b_{12}}{\sqrt{\dfrac{(N_1 - 1)S^2b_{11} + (N_2 - 1)S^2b_{12}}{(N_1 + N_2 - 2)}}}$$

where b_{11} is the education coefficient for group 1, b_{12} is the education coefficient for group 2, S^2b_{11} and S^2b_{12} are the squared standard errors of the coefficients for groups 1 and 2, respectively, and $(N_1 - 1)$ and $(N_2 - 1)$ are the degrees of freedom for group 1 and 2, respectively.

Overall, we may conclude that our data provide a modest, limited support to the second hypothesis. Our data do suggest some variability in the relationship between education and income according to class positions, but it seems that the real significance of the class variable in explaining income inequality is not so much in its interaction with education as in its independent causal influence on the individual's income.

A Modified Class Model

Although the previous analysis has indicated the utility of Wright's classification of "Marxist" class categories in examining income inequality in Korea, there are several problems in his conceptualization, particularly when applied to a developing nation. In what follows, we will discuss some of the limitations of Wright's model and will propose a substantially modified class model which we believe is more appropriate to the study of peripheral capitalist societies.

Probably the most questionable element in Wright's classification is the way he separates managers and supervisors as a distinct class from the working class. His justification is that those who do not legally own the means of production but exercise control over the labor process occupy a "contradictory location" between capitalists and workers, and thus must be treated as a separate class. In effect, this approach amounts to recognizing authority in work organizations as an essential basis of class division, and, as such, this is, as Robinson and Kelley (1979) have already pointed out, a Dahrendorfian rather than a Marxian view.[6]

Wright's scheme, therefore, involves the difficulties of Dahrendorf's approach, which was sharply criticized by Giddens (1973). Giddens argued that (1) authority divisions are basically not dichotomous relations but very often involve a graded hierarchy of relations; (2) "there is no reason to assume . . . that exercise of authority presupposes a (latent) opposition of interest between those in authority and those who are subject to that authority;" and, most crucially, (3) this view "logically implies the recognition of an indeterminate plurality of classes" emerging in every "imperatively coordinated association" ranging from cricket clubs and schools to factories and the state bureaucracy (Giddens, 1973:72–3). The authority division may describe the cleavages within formal or bureaucratic organizations but not cleavages that occur at the societal level because, as Parkin (1971:46) points out, "the lines of authority which cut across each formal organization do not interlock, as it were, to form a major cleavage cutting across society."

Apart from these general difficulties, the utility of the Dahrendorfian scheme is particularly questionable in developing economies where legal ownership and actual control of the means of production are usually in the same hands. In these economies, industrial organizations are typically very small and, consequently, the labor process itself is often controlled by the owners of the enterprises themselves. Elaborate authority hierarchies that do exist in these societies are more likely to be found in state bureaucracies, where graded hierarchies are more likely to exist than dichotomous authority groupings. In fact, Dahrendorf himself did not argue that authority was a major class division in societies that were not industrialized.

Another related problem with Wright's model is his formal and legalistic definition of ownership of the means of production. In that model only legal owners constitute the capitalist class. This approach is contrary to the predominant view of contemporary Marxist scholars, who believe that ownership must be understood substantively rather than juridically. If we take ownership substantively as actual control, then top managers who have the power to assign the means of production to given uses and to dispose of the products thus obtained, must be understood as occupying the capitalist class position (see Poulantzas, 1975). It is difficult to believe that these top managers occupy "contradictory" locations, as may minor supervisors who have control over the labor power of others but who do not have control over the means of production.

---

[6] Wright and Perrone (1977:84ff.) tried to distinguish their approach from Dahrendorf's by arguing that "authority is defined specifically in terms of the social relations of production, not the social relations of any organization whatsoever." But this does not take us very far and offers no practical guideline for actual classification, unless they want to restrict authority relations to particular types of organizations such as "productive" as opposed to "unproductive" ones in the traditional Marxian sense. Wright (1976), however, emphatically denied the importance of this distinction in the earlier article.

A third problematic element in Wright's classification is his attempt to infer ownership of the means of production from self-employment. Although this may be a reasonable assumption in most highly industrialized societies, the same is not true in developing societies where self-employment often conceals a variety of underemployment such as selling homemade juice on the street, shoeshining, and sharpening knives in back alleys. These "marginal" forms of self-employment are, of course, very different from regular shopkeeping or wholesaling. Although the latter activities involve at least a modest amount of capital investment and a stable source of income, the former have none of these. There is a growing recognition that the expansion of this sort of marginal activity (i.e., "marginalization") in large urban centers is a pervasive phenomenon in the less developed countries and may be an unavoidable consequence of the capitalist development in the periphery of the world capitalist system.[7]

The new class model we propose here shares with Wright's model the Marxian premise that classes designate structural positions in the social division of labor. But when it comes to the question of what defines the social division of labor, our conception deviates substantially from the orthodox Marxian notion. We assume that the three most important axes of the social division of labor in the contemporary capitalist economy are (1) ownership or nonownership of the means of production (understood as actual control rather than legal ownership of it), (2) purchase or sale of labor power, and (3) the manual and nonmanual, or white-collar and blue-collar, social division of labor.

The first two are well-known Marxian criteria and therefore require no special explanation. The manual-nonmanual distinction is, however, not a Marxian idea. Yet, probably no other class division is regarded as more important than this one by most non-Marxian scholars. First, it is a significant form of social division of labor; manual and nonmanual workers differ in their relations to the means of production (manual work being more subordinated to the exigencies of machines), to the owners of the means of production (manual workers being more directly exploited by producing surplus value of labor), and to one another (office workers being socially isolated from manual workers on the shop floor). Second, the manual-nonmanual distinction is associated with two distinct levels of "market capacities." In most societies, educational requirement for white-collar jobs is substantially higher than what is required for blue-collar jobs, in that those without secondary or postsecondary educational credentials cannot even compete for white-collar jobs. Third, owing to the above two factors, there usually exists a marked mobility barrier between manual and nonmanual occupations. In most societies, social mobility, both intra- and intergenerational, tends to occur within manual and nonmanual occupations. Unlike Marxist theorists, neo-Weberian scholars such as Parkin (1971) and Giddens (1973) stress the latter two factors, differential market capacities and "mobility closure," as the major bases of class determination (or "class structuration" in Giddens's terms), and here we side with them. Thus, in effect, we propose to substitute a Weberian conception for Dahrendorf's in Wright's model.

There is convincing evidence of considerable meshing of the labor process at the boundary of manual and nonmanual jobs in the United States (Braverman, 1975;

---

[7] "Marginalization" refers to many phenomena in the literature, but in "dependency" literature it usually means "increasing underemployment and poverty" in the urban centers of peripheral nations (Amin, 1976:357). Similarly, "marginality" is often defined as "the lack of difficulty of access to a reasonable and stable income" (Sunkel, 1973:142). See also Johnson (1972) and Peattie (1974) for slightly different definitions.

also Kalleberg and Griffin, 1978). This is partly due to the increasingly mechanized and routinized nature of lower clerical jobs and "feminization" of clerical work, and partly due to the growing power and material rewards of the unionized skilled workers. If this labor process continues, the manual-nonmanual distinction may eventually lose much of its social significance in industrial societies. But such is not the case in developing societies. In them, manual jobs are mostly unskilled work and lower white-collar jobs are not so routinized or feminized as in industrial societies. In most developing societies, the colonial legacy of high authority and prestige associated with office work still persists. Furthermore, access to higher education is much more limited in these societies and, consequently, white-collar occupations that require this scarce qualification enjoy greater material and symbolic advantages. It is thus reasonable to assume that a greater mobility barrier exists across manual and nonmanual positions in developing societies. In short, we believe the manual-nonmanual division to be more important in developing societies than in industrialized societies.

Now that we have isolated three primary axes of the social division of labor, we can combine them to identify five major class categories[8]: (1) the *capitalist class,* which includes legal owners of the means of production who purchase the labor power of others and top managers who have actual control of the means of production—albeit without legal ownership;[9] (2) the *new middle class,* which is composed of the nonmanual salaried employees; (3) the *working class,* which consists of manual workers who are hired by capitalists; (4) the *petite bourgeoisie,* which includes small property owners, mostly shopkeepers, who are either self-employed or employers of one or two helpers; and (5) the *marginal class,* which includes the essentially propertyless self-employed (such as peddlers, street vendors and itinerant repairmen) who are engaged in marginal-scale trade and personal services. Included also in this category are casual laborers and domestic service employees (e.g., barbers, taxi drivers and restaurant employees). Table 5 presents this classification scheme.

Analysis Based on New Class Categories

It is apparent from Table 6 that the marginal class and the working class are the two most underprivileged classes in Seoul. On the average, marginal workers earn less than two-thirds of manual wage workers' income (which itself is very small, about $155 per month) and a little more than a quarter of the shopkeepers' (about $248). Of greater importance may be the enormous gap in income between the white-collar and the blue-collar workers; the latter receive on the average only about one-half of the former's income (about $293). Notice that the income differential between the white- and blue-collar workers (142,240/75,100 = 1.89) is slightly larger than the differential between managers and workers in Wright's model (168,090/94,740 = 1.77).

The first hypothesis concerning the independent effect of class positions on the individual's income is summarized in the regression analysis in Table 7 and reveals that class dummy variables, jointly with education, age, and father's occupation, explain 53.7% of variance of income (see Equation 2). This is substantially larger than the proportion of variance explained by occupational status conjointly with other independent variables (49.9% in Equation 3). If we add class variables to Equation 3 containing occupational status and other causal variables, we can increase the explained variance by 5.8%,

---

[8] Although this class model has been developed primarily with the urban class structure in mind, it may also be applicable to the rural structure. Thus, small independent farmers who constitute a majority of Korean rural population belong to the petite bourgeoisie and tenant farmers or farm laborers to the marginal class, while large landlords may belong to the capitalist class.

[9] Included also in the capitalist class are top-level governmental officials. Our justification for this classification is based on the well-known fact that in Korea, as in many other developing nations, the state exercises an enormous amount of power over the market economy and thus the managers of the state machineries often control the flow and actual disposition of the large amount of capital available to private industrial enterprises.

Table 5. Our New Class Model

Class Categories	Ownership/Control of the Means of Production	Purchase or Sale of the Labor Power	Manual-Nonmanual Distinction
Capitalists	Yes	Purchase[1]	Nonmanual
New Middle Class	No	Sale	Nonmanual
Working Class	No	Sale	Manual
Petite Bourgeoisie	Yes	Self-Employed[2]	Nonmanual[3]
Marginal Class	No	Mostly Self-Employed[4]	Manual

[1] The exceptions are top managers in large corporations and the heads of the state.

[2] The employers of no more than two workers are classified in the petit bourgeois category.

[3] Small independent business is commonly regarded as a nonmanual occupation, but actually the manual-nonmanual distinction is not very relevant to this type of work.

[4] Although the marginal class consists mainly of workers on own account without viable capital (indicated by the absence of any permanent shop for trade), it also includes casual laborers and domestic service employees whose employment is basically temporary and unstable in nature.

whereas if we add occupational status to Equation 2, the increase is only 2.0%. It seems clear that the class variable has a greater explanatory power than occupational prestige has.

Looking at the content of Table 7 more closely, we note that the capitalist class clearly occupies the most privileged position in Seoul. Employers and top managers in this class earn as a whole 61,504 won more than manual wage workers, even after adjusting for the effects of education, age, and family background (see Equation 2); holding the same factors constant they are making 42,386 won (61,504 – 19,118) more than the white-collar workers, and 38,385 won (61,504 – 23,119) more than shopkeepers.

On the opposite end of the class structure, we notice that the marginal class is clearly the most disadvantaged one in Seoul. We have noted already that marginal workers' average income is markedly lower than that of the wage-earning workers. Table 7, additionally, suggests that income difference between these two classes is not solely due to the individual characteristics of their members but, more importantly, due to their differential structural positions in the total organization of urban economy; thus, even after holding other causal factors constant, we find an income difference of 30,523 won between blue-collar and marginal workers.

In contrast, the petite bourgeoisie seem to make higher incomes (after education and other variables are controlled), than not only the blue-collar or marginal workers but also the white-collar workers. This income advantage of the petite bourgeoisie is most likely to be derived from property ownership which characterizes its members, a variable which is not included in the regression equations. In any event, the finding is unambiguous in showing that the social classes that are based on ownership or control of the means of production, large or small, enjoy definite advantages over other classes in the economic reward system of Korean society.

Table 6. Means and Standard Deviations (in Parentheses) of Major Variables by New Class Categories

Class Categories	Income	Education	Age	Occupational Status	Father's Occupation	Percent Farm	N
Capitalist Class	182,050	4.6	45.0	54.1	4.2	57%	128
	(89,670)	(1.5)	(9.5)	(10.8)	(1.0)

	(59,520)	(1.4)	(8.8)	(10.6)	(0.9)		
Marginal Class	47,380	2.8	43.4	31.5	3.6	68%	107
	(23,270)	(1.2)	(10.0)	(11.6)	(1.0)		

Table 7. Regression of Income on New Class Categories and Other Causal Factors of Income (Standard Regression Coefficients Are in Parentheses)

				Dependent Variable = Income						
Constant	Education	Age	Father's Occupation	Farm-Nonfarm	Occupational Status	Capitalist Dummy	New Middle Dummy	Petit Bourg. Dummy	Marginal Dummy	R²
(1) −100,085	15,263	1,566	3,346*	−1,573*	1,646	38,957	246*	12,775*	−27,127	.557
	(.32)	(.19)	(.05)	(−.01)	(.28)	(.21)	(.00)	(.07)	(−.14)	
(2) −72,881	21,063	1,798	3,988*	−1,072*	—	61,504	19,118	23,119	−30,523	.537
	(.44)	(.22)	(.06)	(−.01)	—	(.33)	(.12)	(.13)	(−.15)	
(3) −133,606	14,286	1,722	3,134*	−1,432*	2,475	—	—	—	—	.499
	(.30)	(.21)	(.04)	(−.01)	(.43)	—	—	—	—	

* Coefficient less than twice its standard error.

In Equation 1, which includes occupational prestige, the coefficients of the new middle class and the petit bourgeois dummies become statistically nonsignificant, which means that income differences between these two classes and the manual working class are not significant when statistical adjustment is made for the effects of occupational status and other variables. This is to be expected since the white-collar and blue-collar distinction contains a heavy status component, while small business owners are usually accorded higher occupational prestige than the blue-collar workers. In general, our class model has greater overlap than Wright's model with the occupational prestige hierarchy. However, an F-test of the overall effect of the class variable as a whole, as was conducted with Table 3 before, shows that the class effect, independent of occupational prestige and other causal variables, is statistically significant at .001 level ($F=19.4$ with 4 and 675 degrees of freedom).

Now let us turn to the question of whether class position influences the way in which education affects income. As before, we conducted a separate regression analysis for each class category to compare regression coefficients of education across class categories. In the following equations only one control variable of age is introduced because father's occupational status and farm-nonfarm background were shown to be mostly insignificant, both statistically and substantively, in predicting income within class categories. The figures in parentheses indicate standard errors.

$$\begin{aligned}\text{Capitalist}\\ \text{Income} &= -117{,}280\\ &\quad + 31{,}620\ \text{Educ.}\\ &\qquad (4{,}270)\\ &\quad + 3{,}470\ \text{Age}\\ &\qquad (682)\\ &\quad (R^2 = .39)\end{aligned}$$

$$\begin{aligned}\text{White-Collar}\\ \text{Income} &= -97{,}700\\ &\quad + 30{,}110\ \text{Educ.}\\ &\qquad (3{,}460)\\ &\quad + 2{,}140\ \text{Age}\\ &\qquad (530)\\ &\quad (R^2 = .31)\end{aligned}$$

$$\text{Blue-Collar Income} = 2{,}420 + \underset{(2{,}760)}{14{,}200\ \text{Educ.}} + \underset{(360)}{720\ \text{Age}} \quad (R^2 = .22)$$

$$\text{Petit Bourgeois Income} = -44{,}110 + \underset{(3{,}540)}{21{,}750\ \text{Educ.}} + \underset{(530)}{1{,}950\ \text{Age}} \quad (R^2 = .24)$$

$$\text{Marginal Worker Income} = 54{,}920 + \underset{(267)}{1{,}350\ \text{Educ.}} + \underset{(200)}{280\ \text{Age}} \quad (R^2 = .20)$$

It is shown that income return to education is highest for capitalists and white-collar workers and lowest for marginal workers. Among two intermediate groups, shopkeepers are likely to receive significantly larger income returns than blue-collar workers. Table 8 displays differences of regression slopes (i.e., returns to education) between working-class and other class categories and the corresponding t-values. All these differences turned out to be significant at the .01 level.

Table 8. Selective Comparison of Class-Specific Regression Coefficients of Education and t-Values of Differences

Comparison	Difference in Education Coefficient	t-Value
Capitalist vs. Working Class	17,430	4.7*
New Middle vs. Working Class	15,910	4.9*
Petite Bourg. vs. Working Class	7,550	2.3*
Working Class vs. Marginal	9,540	4.1*
Capitalist vs. New Middle	1,520	.4
New Middle vs. Petite Bourg.	8,360	2.4*
Petite Bourg. vs. Marginal	17,090	5.8*

* Significant at .01 level with one-tail significance test.

Special attention needs to be paid to differences between white-collar and blue-collar workers. In spite of similarity in their labor market situations (i.e., both sell their labor power and are most likely to be employed in bureaucratic organizational settings), education seems to have differential impact for the two categories of workers. For each additional educational level, the members of the new middle class receive more than twice the amount of income received by the members of the working class. This is a strong indication of the privilege which the former enjoys over the latter in the reward structure of Korea. The blue-collar workers fare badly even in comparison with small shopkeepers; for each increment in education, the latter receive 7,550 won more than the former. As expected, education makes little difference for marginal workers. In both independent and interactive effects, their class position is characterized by true "marginality."

A question can be raised as to whether the smaller education effects found for the blue-collar and the marginal workers are an artificial result of treating education as an interval datum. It is true that education is not precisely an interval variable because two years of elementary school education would not be the same as two years of college education in affecting social rewards. Since manual workers are clustered at the lower end of the education scale where the income effect is relatively small, it is possible that lower income returns to education for these two class categories are a result of these scale-specific qualities rather than class interaction.

To check against this possibility, we calculated separate regression equations using educational credential dummy variables. (For simplicity of comparison, we grouped educational levels into three categories producing two dummy variables: high school—completion or noncompletion of high school; college—having or not having a college diploma.) The results shown in Appendix I, however, reveal no important discrepancies from the above findings, except that educational income returns for the capitalists turned out to be greater than shown above. It remains unchanged that blue-collar and marginal workers receive considerably lower incomes than white-collar workers or the petite bourgeoisie for each educational level increment.

In all, the class categories we have developed prove to have greater explanatory power than Wright's categories in both their independent and interactive effects on the individual's income in Seoul. This improvement seems to be primarily due to our recognition of the significant internal division among those who exist outside the organized labor market and secondarily to the more realistic perception of class boundaries in the dominant capitalistic sector.

Conclusion and Discussion

The dominant conclusion of the present analysis is that class categories, conceived principally in terms of the social division of labor, are more consequential than occupational prestige in determining individuals' incomes, in both advanced and developing capitalist societies. This conclusion seems to hold regardless of specific class models adopted in the present analysis, although our model seems to have a greater explanatory power than Wright's in the context of the Korean metropolitan center.

It must be admitted that the real value of this kind of analysis pertains not so much to the framework of Marxian class relations as to that of status attainment. It would be wrong if we argue that this study has established the overall validity of Marxian class theory. For class in Marxian theory means a much broader and more complicated relational process, and our data analysis has not really addressed the nature and quality of relations between social classes, let alone the consciousness of the individuals in these class positions.

Granting these limitations, we believe our study, nevertheless, sheds light on some important features of the Korean class structure which might be generalizable in other peripheral capitalist societies. First of all, our data revealed the quantitative significance of the self-employed—the labor force which is untouched by the wage labor system. The mode of production represented by this labor force is regarded as "simple commodity production" or "precapitalistic." Marx treated this element as "transitional" and based his theory largely on the relations of production within the predominantly capitalist mode of production. As such, the labor force that is not absorbed into the wage system occupies only a residual category in Marx's class model. As shown by our sample data, this element of the Marxian theory of class causes serious limitations in grasping the total reality of the class system in Korea; and these limitations apply to the majority of less developed nations where the self-employed represent 30% to 60% of the urban labor force.

Thus, an adequate approach to the class system in peripheral societies must pay close attention not only to the relations of production within the predominantly capitalistic mode of production but also to the relations within the simple mode of commodity production and, further, to the nature of relations between these two modes of production. There is increasing awareness of these problems among contemporary Marxist scholars, particularly concerning the question of "articulation" of the modes of production, but no satisfactory approach has been developed in the literature (see Foster-Carter, 1978).

In this connection we must consider the "center-periphery" model, which has received much attention recently in dependency literature. Center-periphery relations may be conceptualized in two ways: At the level of international relations, they refer to the relationships between the advanced capitalist countries and the economically underdeveloped dependent countries; at the domestic or national level, they involve the relationships between the industrial, modernized sectors or regions, and the backward, poor sectors or regions. It is central to dependency theories that these external and internal dimensions of the center-periphery relations are structurally similar, interlocked, and mutually reinforcing, for both are viewed as the consequences and manifestations of one single process, the evolution of the world capitalist system.

From this perspective, dependency writers advanced an important proposition that in the peripheral economies the economic sectors or groups that are closely linked to metropolitan capital (i.e., the "internationalized sector") prosper, while those that are segregated from it suffer growing material deprivation and unemployment. It is thus hypothesized, as Portes (1976:76) notes, that "the basic cleavage in these new quasi-industrial societies does not occur between traditional peasant and landowning classes or even between domestic bourgeoisie and urban proletariat but between groups linked with the foreign-owned sector (workers and employers alike) and the rest of the population." Carried a little further, this hypothesis implies "the replacement of class struggle by a sectoral struggle between those connected with the internationalized sector and those marginal to it" (O'Brien, 1975:19).

Unfortunately this hypothesis cannot be directly tested with our data because we are unable to distinguish the internationalized sector from the domestic or marginal sector. But there are some indirect ways in which we can at least partially assess the validity of this center-periphery hypothesis. One approach is by using the size of work organization (number of employees) as a rough measure of sectoral division, assuming that the internationalized sector is capital- and technology-intensive and highly bureaucratized, whereas the domestic sector enterprises are, for the most part, small-scale, utilizing little capital and simple technologies. We chose an arbitrary cutoff point at 30 employees and created a new dummy variable in which the enterprises employing 30 or more workers were regarded as belonging to the center sector, while those with fewer than 30 employees belonged to the periphery. A regression analysis was then conducted in a similar manner to the previous analysis. The results, displayed in Appendix II, show that the sectoral division has no significant effect on income, controlling for education, age, and occupational status. Inclusion of this dummy variable in the equation containing education, age, and occupational status adds nothing to the explained variance. The substitution of this sectoral variable with other sectoral dummies using different cutoff points (100 employees or 300 employees) produces virtually the same results.

In connection with this analysis, we should note that our previous findings have a definite bearing on the sectoral hypothesis at hand. Of the five social classes differentiated in our model, the petite bourgeoisie and the marginal class belong to the domestic or periphery sector, while the majority of white-collar and blue-collar workers in our sample participates in what can be regarded as the internationalized sector in the predominantly export-oriented economy of Seoul. Now, how consistent are our findings with the prediction of the center-periphery polarization hypothesis? There is no question that marginality, in its quantitative and qualitative dimensions, is an economic reality of this society. It may also be true that in this society the most serious economic deprivation does not occur in the form of typical capitalistic exploitation but rather in the failure of the people to enter into even such exploitative relations in the modern industrial sectors. But it is also true that the overall economic conditions of the industrial workers (71% of whom belong to the center sector by the above definition) are not tremendously better than those of the marginal workers. Our data revealed that the deprivation of proletarians seems equally critical (only about half of the average income of the new middle class), and the slight advantages they enjoy over the "subproletariat" may mean very little to their life chances. In comparison, many small property owners in the peripheral sector seem to be doing remarkably well economically. With the effect of education controlled, the petite bourgeoisie appear, in fact, to be earning more money than white-collar workers. There is little sign that all the workers who are excluded from the internationalized sector suffer growing material deprivation and marginality. Nor is there any convincing ground to assume that the workers participating in the internationalized sector benefit disproportionately from "dependent development" (Cardoso, 1972).

Although our data are very tentative in nature, we side with the view that the peripheral social formation consists of more than one mode of production. Here we identified two distinct modes of production, the capitalistic mode of production and simple commodity production, and we regard their interrelationships as problematic rather than as that of a simple "chain of exploitation."[10] It is our viewpoint that in developing societies the most crucial class relations are also defined by the capitalist relations of production, that is, by capital-labor relations, but actual political and ideological manifestations of these class relations are defined not simply by the relations of production within the capitalistic mode of production, but also by the ways this mode is articulated with other modes of production, and, consequently, by the nature of alliances between classes across different modes of production. In short, class analysis in peripheral capitalism must tackle immensely more multiplicative processes of class relations than envisioned by a traditional Marxist class model.

THE STRUCTURE OF ATTITUDE SYSTEMS IN THE GENERAL PUBLIC: COMPARISONS OF A STRUCTURAL EQUATION MODEL*

CHARLES M. JUDD
Harvard University

MICHAEL A. MILBURN
University of Massachusetts-Boston

American Sociological Review 1980, Vol. 45 (August):627–643

Philip Converse and other theorists have argued that the public at large does not have meaningful and stable attitudes. Specifically, they have argued that the public's attitudes, as compared to those of the political "elite," show less stability over time and less consistency between issues and are less likely to be based upon an underlying ideological predisposition. These hypotheses have been supported, generally, by computing correlations between attitude questions and comparing them between public and elite samples. The present paper examines all three hypotheses using a structural equation approach. This allows us to: (a) test for a single common underlying ideological construct; (b) separate ideological stability from issue-specific stability; and (c) use unstandardized structural coefficients to make between-sample comparisons. Using panel data from 1972–1974–1976 national surveys, we find that both the highly educated and the uneducated public show evidence of an underlying ideological predisposition, show remarkable stability in their attitudes, and show equal consistency or constraint between different attitude issues.

A great deal of research in sociology is predicated on the notion that the public's attitudes on social issues, as measured by surveys and opinion polls, are relatively meaningful and stable. Various sociologists (Alwin, 1973; 1976; Wheaton et al., 1977) have examined attitude stability by suggesting models for estimating simultaneously the reliability and stability of attitudes over time. While this research certainly recognizes that survey measures of attitudes are affected by measurement error, it is generally assumed here, and elsewhere, that there is, in fact, some relatively stable underlying attitude, possessed by the respondent, which contributes to responses to attitude questions. Opinion polls are meaningful for researchers and for policy makers only if such an assumption is made.

While the assumption may seem to many to be trivial and obvious, there exists in the social sciences a substantial body of literature which has called it into question. In particular, Philip Converse (1964; 1970; 1975) has repeatedly questioned whether attitude responses from members of the public reflect anything more than spur-of-the-moment, random responses. Converse (1964:245) has compared the attitude responses of the mass public to responses from politically involved "elites" in making the argument that "large portions of an electorate do not have meaningful beliefs, even on issues that have formed the basis for intense political controversy among elites for substantial periods of time."

The Characterization of Attitude Systems

The comparison of attitude systems between the public at large and elites has been primarily along two related dimensions: (1) the degree of constraint among various political attitudes, and (2) the degree to which those specific attitudes are derived from and reflect a more general ideological position on an underlying liberal-conservative continuum.

Constraint among attitudes. Attitude constraint has been defined by Converse (1964:207) as "the success we would have in predicting, given initial knowledge that an individual holds a specified attitude, that he holds certain further ideas and attitudes." Traditionally, it has referred to two types of predictability between attitudes: between attitudes on different is-

sues at the same point in time, and between attitudes on the same issue at different points in time. To discriminate between these two types of attitude predictability, we refer to the first as attitude constraint and to the second as attitude stability.

Differences in attitude constraint between the public at large and elites usually have been assessed by intercorrelating attitude measures at one point in time, separately for each of the two groups. The averages of these two sets of correlations are then used to compare the attitude constraint of elites and nonelites. Comparing 1958 congressional candidates to a cross-section of the national electorate, Converse (1964:229) found that the average association[1] among four domestic attitude issues was .53 for elites and .23 for the general population. Thus, Converse concludes that the attitudes of elites are much more constrained than those of nonelites.

A similar procedure has been used to assess attitude stability, although, in his original presentation, Converse (1964) reports on stability only for his nonelite sample. Using data collected at two-year intervals from 1956 to 1960, Converse reports that the average within-item, over-time correlation is approximately .36. While comparable data are not available on the elite sample, Converse clearly concludes that the nonelites show a remarkable lack of stability in their attitudes.

General ideological basis of attitudes. As the second dimension for comparison between elites and nonelites, Converse focuses upon the degree to which specific attitudes are organized or are consistent with a general ideological liberal-conservative continuum. Studies have traditionally measured the degree of such ideological organization by coding responses to open-ended questions on political candidates for the extent to which they refer to ideological principles (Campbell et al., 1960; Converse, 1964; Field and Anderson, 1969; Nie et al., 1976). Using such a coding procedure, Converse (1964) reports that only 2.5% of his American electorate sample consistently use a general ideological continuum in evaluating candidates. Another 9% peripherally refer to a general ideological continuum, and the remaining 88.5% of the sample fail to use any ideological dimension in answering the questions. Converse concludes from this analysis that most of the electorate tend not to refer to general ideological principles in evaluating issues or political candidates.

The relationship between these two dimensions—which Converse (1964) has used to characterize differences in attitude systems between elites and nonelites—is probably apparent to the reader. If a general ideological principle is used to some extent for evaluating issues, then attitudes on those issues should tend to be intercorrelated to at least that extent. In other words, specific attitude items should correlate with each other if they are derived from the same general underlying ideological predisposition.

Research on the attitude systems of elite and nonelite samples has been fairly prolific since Converse's (1964) original presentation. Some of this research has been critical of the methods employed by Converse to support his conclusions. A number of researchers have suggested that measurement error, vagueness in the wording of questions, or response variation without "true" attitude change may cause low interitem correlations without these necessarily reflecting random or meaningless attitudes (Achen, 1975; Pierce and Rose, 1974). Weissberg (1976) and Barton and Parsons (1977) have argued that differences in correlations between samples may be, in part, due to differences in response variance within samples. They suggest that Converse's conclusions may be biased because of differing variances in the two samples.

Some, including Converse himself (Converse and Markus, 1979), have used more recent data to amend, criticize, or support the original conclusions. Nie and his colleagues (Nie and Anderson, 1974; Nie et al., 1976) examined the constraint of elites and nonelites using national political surveys conducted during the sixties and early seventies. They note that a sharp increase in attitude constraint for the American electorate occurred in 1964 and continued through 1972, setting attitude constraint at a level roughly comparable to that of the elites in the late 1950s. Some increase in the use of ideological principles also occurred at the same time, although the shift was considerably less dramatic (Field and Anderson, 1969).

---

[1] These statistics are tau gammas rather than the more familiar product moment correlations.

Luttbeg (1968) collected cross-sectional data from samples of political leaders in Oregon, and of the public at large in that same state, in 1959. Instead of comparing average correlations between attitude items from the two samples, Luttbeg separately factor analyzed the two correlation matrices. Converse's (1964) research suggests that a "simpler" factor structure should be found for the elites than for the nonelites. In other words, in the analysis of the elite sample, one or a very few factors should explain most of the common or shared variance in the attitude items, while in the nonelite sample many more factors should be required to explain an equal amount of variance. In fact, if (as Converse argues) there tends to be a single abstract ideological continuum that is the basis for attitude positions among elites, then we should expect that most of the common variance in responses should be explained by a single factor. Luttbeg (1968) finds that this is far from the case. While the factor structure for the elite's correlation matrix was somewhat simpler than for the matrix from the nonelite sample, there emerged five meaningful and substantial factors in both samples. Thus, Luttbeg's study supports the notion of slightly higher constraint among elites than among nonelites; however, it suggests that, even for elites, there is no single ideological continuum that serves as a base for all of the local attitude issues examined in the study.

Bishop et al., (1980) have examined constraint and stability in two small samples which differ in educational background. The attitudes of both samples on seven national issues were measured at two points in time, separated by an average of ten months. While the two samples differed in the degree of constraint between items, thus supporting Converse's (1964) conclusion, both samples showed quite high over-time stability in their attitudes. Like most other studies, correlations between items and over time were examined. The abstract ideological base of the attitudes was not examined, either via coding open-ended questions or by factor analyzing the correlation matrices.

Most recently, Converse and Markus (1979) have argued that panel data collected during the years 1972–1974–1976 by the University of Michigan show almost identical stability correlations as the original 1956–1960 panel survey. They make no mention of attitude constraint, however, in these data; nor do they engage in elite vs. nonelite comparisons.

As is apparent from this brief review, Converse's (1964) original hypotheses have been supported by some studies and disconfirmed by others. There has been surprisingly little consensus among those who have sought to replicate or criticize Converse's work.

Problems in the Traditional Assessment of Constraint and Ideological Basis of Attitudes

In the research on attitude structure in elite and nonelite samples there are three primary analytic problems which may be responsible, in part, for the inconclusive results. Our discussion of these problems borrows notions from sociologists who have been concerned with models of reliability and stability in panel data (e.g., Wheaton et al., 1977).

First, the extent to which attitudes reflect a single underlying ideological base has been ambiguously assessed in the past. Converse (1964) and others originally coded open-ended responses for ideological content. It is never clear what their criteria for coding were nor with what reliability the coding was conducted. Further, it is questionable whether the responses to open-ended questions concerning political candidates adequately assess whether responses to close-ended attitude measures are ideologically derived. Certainly it may be possible to register attitudes that are idelogically derived and yet evaluate a political candidate solely on the basis of idiosyncratic, nonideological reasons (for example, I dislike him because he's fat and smokes cigars).

As has been suggested, the assessment of an ideological base in attitude responses is probably best conducted by examining the structure of matrices of correlations between attitude items through factor analysis. If there is a single liberal-conservative ideological dimension that is reflected in all specific attitudes for some sample, then we would expect correlations among those attitudes to exhibit a single common-factor structure. Happily, tests for the number of common factors in a correlation matrix have recently been developed which permit us to examine the common ideological base of a set of attitude responses. These procedures use maximum likelihood factor analysis models in a confirmatory, rather than exploratory, manner (Jöreskog and Sörbom, 1978; Kenny, 1979).

The second major problem in the assessment of attitude structure and its comparison between elite and nonelite samples concerns the well-known fact that correlations between variables are affected by the variances of the correlated variables (Blalock, 1967). Therefore, comparisons between samples of correlations may well be affected by differences within the samples in the variances of the variable. Barton and Parsons (1977) and Mueller and Judd (1979) have discussed this problem in the comparison of attitude structures at some length. The problem arises from the fact that a correlation between two variables is equivalent to the covariance between the two variables in standardized form (transformed so their means equal zero with unit standard deviations). If the standard deviations in two groups on the same variables differ, then the correlations may differ even if unstandardized coefficients between the measures are equal. The solution to this dilemma, if all items are measured on the same scales—and, hence, have the same metric—is to compare unstandardized or structural coefficients rather than correlations (Duncan, 1975; Kenny, 1979). Unfortunately, this solution is more difficult when dealing with factor analysis where the variances of underlying factors are unobserved. However, assumptions can be made about the metrics of factors which permit the estimation of unstandardized coefficients, as we will explain.

The final problem in the assessment of attitude structure concerns the fact that at least two sources of attitude stability are confounded in its traditional test-retest correlation. We might conceive of variation in attitude responses to any item, at any point in time, being caused by at least three different constructs or factors. First, to some extent, variance in responses to a given attitude question may be due to variation in the underlying ideological continuum which explains variance in all attitude responses at any one point in time. In factor analytic terms, there exist one or more common factors which explain item variance at any one point in time. In addition, there may exist variation in a given attitude at one point in time that is *not* associated with variation in other attitudes at that point, but that *is* associated with variation in the same attitude at another point in time. In other words, there may exist variation in response to an item that is not caused by any underlying general ideological factor but that, nevertheless, shows over-time stability. Finally, variation in response to an item may be, in part, made up of random error and other components that are idiosyncratic to that particular attitude at that point in time. This portion of variation is correlated neither with other attitude items at the same time nor with the same attitude item at different points in time.

These three components of variance in an attitude item can be expressed in the equation,

$$X_{ij} = \sum_{k} \alpha_{ijk} T_{jk} + \beta_{ij} I_i + U_{ij}, \qquad (1)$$

where X_{ij} refers to a response on the i^{th} attitude item at time j; T_{jk} is the set of k common factors which explains covariance between items at any one point in time (in the case of a single underlying ideological construct, k = 1); I_i is an item-specific factor which explains covariance between the same items at various points in time; U_{ij} is disturbance or residual variation in X_{ij} not associated with T_{jk} or I_i; and α_{ijk} and β_{ij} are structural coefficients (or factor loadings in the language of factor analysis). In this model we are assuming that T_{jk}, I_i, and U_{ij} are all uncorrelated with each other and that the expected values of X_{ij}, T_{jk}, I_i, and U_{ij} are all zero. It is further assumed that the item-specific factor, I_i, for any given attitude question is uncorrelated with the item-specific factors of other attitude questions.

This equation, which specifies the components of variation in any observed attitude response (X_{ij}), gives rise to two sorts of attitude stability. First of all, there may be more or less stability in the underlying time-specific common factors (T_{jk}). Second, there may also be stability in the item-specific components of variance (I_i). Converse (1964) and others have recognized that teasing apart these two bases of stability is important, although they have been unable to do so adequately. The former represents stability in general ideological position, regardless of issue; the latter is issue-specific stability, independent of general ideological stance.

Stability in the common time-specific factors can be determined by examining either the correlations or the structural coefficients between the T_{jk}'s at various points in time (j = 1, 2, and 3). As we have already seen, comparisons between populations are more properly conducted using structural coefficients than using correlations. Thus, to assess stability in the time-specific common factors, we need to posit a causal or structural model among them and estimate the coefficients of that model. The structural model we assume among the T_{jk} is the fully recursive model described by the following structural equations:

$$T_{2k} = \gamma_{21} T_{1k} + V_{2k}, \text{ and} \quad (2)$$

$$T_{3k} = \gamma_{31} T_{1k} + \gamma_{32} T_{2k} = V_{2k}, \quad (3)$$

where the T_{jk}'s are as previously defined, γ_{ij} is a set of structural coefficients, and V_{jk} is the disturbance or residual variation in the endogenous construct of interest. Thus, we assume that the common underlying ideology at any one point in time is caused by that same ideology or factor at prior points in time.

The second sort of stability, that concerning the stability of the item-specific component of variance in any X_{ij}, is examined by inspection of the I_i structural coefficients (β_{ij}) in Equation 1.

An example of the combined measurement model (Equation 1) and the structural model among the latent constructs or factors (Equations 2 and 3) is depicted in Figure 1. In this figure, we assume that the two attitudes, X_{ij}, are measured at three points in time. We also assume that there is only one common ideological factor at any point in time (k = 1).

The Present Study

Using national survey data from the 1972–1974–1976 panel study conducted by the Institute for Social Research at the University of Michigan, we attempt in the present study to examine attitude constraint, stability, and ideological base in highly educated and less educated populations, while overcoming the three analytic problems discussed above. We use the same data as those reported by Converse and Markus (1979). At each of the three years, all respondents answered a set of five attitude questions. A model similar to that presented in Figure 1 (with i=5, j=3, and k=1) is developed for each sample, and comparisons are made between the samples.

To estimate the coefficients of the model and to test formally differences between the populations in the coefficients of the model, the computer program LISREL (Jöreskog and Sörbom, 1978: Version 4) is employed. LISREL is a general procedure for estimating the unknown parameters of structural equation models. It permits us to constrain certain parameters (both within and between samples), allows others to freely converge to maximum likelihood estimates, and provides a goodness-of-fit test between the model and the sample variance/covariance matrices of the variables (X_{ij}'s).

METHODS

Samples

The data we report on were gathered by the Center for Political Studies at the University of Michigan. They were collected from a national panel sample interviewed

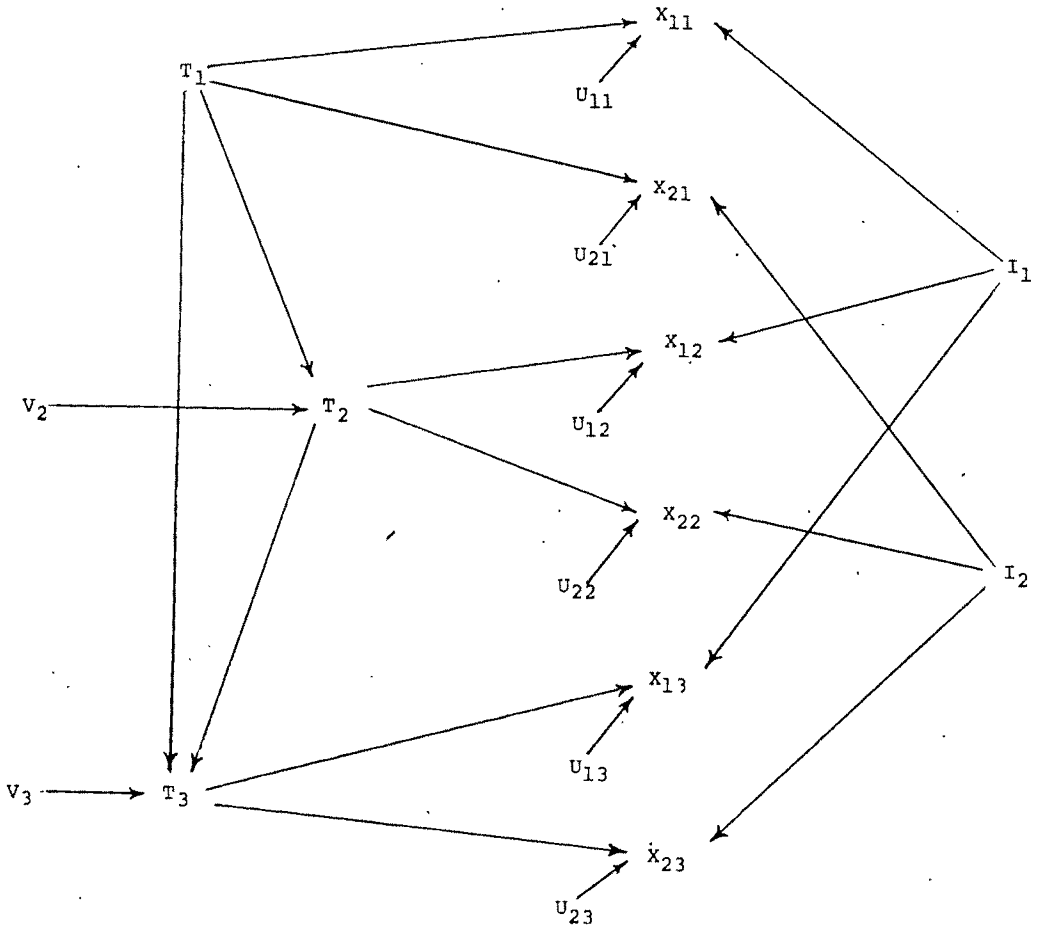

Figure 1. Structural Model of Two Attitudes (X_{1i}, X_{2i}) Measured at Three Points in Time

during the election years 1972, 1974, and 1976. Respondents were interviewed before and after the elections in each of these years.

The full sample in the three-wave panel survey consisted of 1,320 respondents. Of these, 464 respondents had complete data on all attitude questions which were used for our analysis. Because of the substantial number of cases (856) which were omitted from the analysis due to missing data, generalization from our results should be tentative.

In order to form elite and nonelite comparison groups, the sample of 464 respondents was broken down by a number of education and political-involvement variables. In the literature that we have reviewed on attitude belief-systems, there seems to be some confusion over the variables which should be used to discriminate between elites and nonelites. Conceptually, there is agreement that elites are relatively well educated and politically articulate; operationally, many different variables have been used to identify them. For our purposes, it seems reasonable to use educational level as a way of differentiating between elites and nonelites. Emphasizing education as the discriminating variable is consistent with both prior theory (Converse, 1964) and research (Bishop et al., 1980; Stimson, 1975). As Bishop et al. point out, it seems reasonable to believe that education should affect attitude constraint and stability because higher education is commonly seen as encouraging people to relate issues to each other and to be consistent in their thinking.

Of our 464 respondents, 203 (44%) had not attended college, 118 (25%) had attended some college but less than four years, and 143 (31%) respondents had attended four years of college or more. For purposes of analysis, the last group was defined as our elite sample, the first as our nonelite sample. Respondents who had attended some college but less than four years were not included in either group in order to clearly discriminate between our elite and nonelite samples.

Measures

Respondents' attitudes on five different issues were collected at each of the three waves of the panel survey and were used in our analysis. The five questions, all answered on seven-point self-rating scales, are as follows:

(1) Some people think achieving racial integration of schools is so important that it justifies busing children to schools out of their own neighborhood. Others think letting children go to their neighborhood schools is so important that they oppose busing. Where would you place yourself on this scale (1 = Bus to achieve integration; 7 = Keep children in neighborhood schools)?

(2) Some people are primarily concerned with doing everything possible to protect the legal rights of those accused of committing crimes. Others feel that it is more important to stop criminal activity even at the risk of reducing the rights of the accused. Where would you place yourself on this scale (1 = Protect rights of accused; 7 = Stop crime regardless of rights of accused)?

(3) Some people feel that the government in Washington should make every possible effort to improve the social and economic position of blacks and other minority groups. Others feel that the government should not make any special effort to help minorities because they should help themselves. Where would you place yourself on this scale (1 = Government should help minority groups; 7 = Minority groups should help themselves)?

(4) Some people feel that the government in Washington should see to it that every person has a job and a good standard of living. Others think that the government should just let each person get ahead on his own. Where would you place yourself on this scale (1 = Government see to job and good standard of living; 7 = Government let each person get ahead on his own)?

(5) We hear a lot of talk these days about liberals and conservatives. Here is a seven-point scale on which the political views that people might hold are arranged from extremely liberal to extremely conservative. Where would you place yourself on this scale (1 = Extremely liberal; 7 = Extremely conservative)?

As is apparent, the last question measured attitudes on the general liberal-conservative continuum rather than on a specific issue. As will be discussed below, this measure was used to assign a metric to the common factor. Respondents also gave their attitudes on other issues which were not used in this analysis (for example, Vietnam war, marijuana, national health insurance). These were omitted because they were not asked at all three years of the full sample.[2]

The Model

The model we propose is quite similar to a class of stability models discussed by Wheaton et al. (1977). In this model, variation in attitude responses to each question is assumed to be due to three components:

$$X_{ij} = \sum_{k} \alpha_{ijk} T_{jk} + \beta_{ij} I_i + U_{ij}, \tag{4}$$

where X_{ij} is a response to the i^th^ question at time j; T_{jk} is a time-specific common factor or latent construct that explains covariance between items at time j; I_i is an item-specific factor or construct explaining covariance between the same items across time; and U_{ij} is disturbance or residual variation in X_{ij}. In order to test for a single common factor for the five items at any one point in time, we set k = 1. This model differs from those of Wheaton et al. (1977) in our specification of an item-specific factor for each item (I_i), as well as an error component (U_{ij}), instead of allowing errors of measurement to be correlated between the same measure at different time points.

---

[2] The issue of women's role in society was asked of all respondents and was included in preliminary analyses. It was omitted from the final model, however, because of very low correlations between it and the other issues, especially in the elite sample. Other studies have also found anomalous results when this issue was included (Bishop et al., 1980).

The above equation describes what is called the measurement model, the structural effects of unmeasured constructs upon the observed variables or indicators. In addition, we assume a structural model among our latent constructs. In this model, all I_i are assumed to be uncorrelated—as are all U_{ij}. Further, both of these sets of constructs are assumed to be uncorrelated either with each other or with T_j.[3] The structural model among the T_j is described by the following equations:

$$T_2 = \gamma_{21} T_1 + V_2, \text{ and} \qquad (5)$$
$$T_3 = \gamma_{31} T_1 + \gamma_{32} T_2 + V_3, \qquad (6)$$

where the gammas are structural coefficients and the V_j are disturbance or residual variances.

Attitude constraint in the two samples is assessed in this model by examining the α_{ij} structural coefficients. Two sorts of attitude stability are assessed by focusing on different structural coefficients: (a) stability in the general ideological position or in the common time-specific factors (T_j) is estimated by the γ_{ij} structural coefficients; and (b) stability in the item-specific components of variance is estimated by the β_{ij} structural coefficients. Finally, as we have said, the use of a single underlying ideological continuum by both groups is examined by allowing only a single time-specific common factor (T_j) at any point in time and testing the quality of fit of the model to the sample data.

Estimation

The unknown parameters of the model were estimated in the two samples simultaneously using the LISREL procedure (Jöreskog and Sörbom, 1978:Version 4). This procedure generates maximum-likelihood parameter estimates under the assumption of multivariate normality. The following unknown parameters were estimated:

(a) the structural coefficients of latent constructs upon the indicators (α_{ij} and β_{ij});

(b) the structural coefficients among the latent constructs (γ_{ij});

(c) the variances of disturbances to the indicators (U_{ij});

(d) the variances of disturbances to the latent endogenous constructs (V_j); and

(e) the variances of all latent constructs.

Estimation of the coefficients of the model is possible only if the model is identified. This means that there must exist sufficient information in the sample variance-covariance matrices to solve for the unknown coefficients. If there is more information in the matrices than needed, a set of overidentifying restrictions exist that can be used to test whether in fact the sample data are consistent with the model that has been hypothesized (Kenny, 1979). An overall goodness-of-fit test (χ^2) is performed by the LISREL procedure which amounts to a simultaneous test of all overidentifying restrictions. If the model is consistent with the sample data, this χ^2 should not reach traditional significance levels.

In the present case, we want to test the quality of fit of the model to two samples simultaneously. In such cases, the goodness-of-fit test (χ^2) generated by LISREL tests the hypothesis that the model holds in each population, simultaneously. In addition, it is possible to impose between-sample constraints on parameters of the model and, thereby, to test, for instance, whether structural coefficients are equal in two populations yet allow the variances of both constructs and indicators in the two populations to differ. For our purposes we can define a hierarchy of models that can be examined, these models differing in the extent to which between-sample constraints upon parameters are imposed. At the lowest level, we impose no between-sample constraints upon the model parameters. Thus the χ^2 test at this level tests whether the same structural model explains the observed data in both populations, allowing both the structural coefficients and the variances of unobserved constructs to differ. At the highest level, we might specify that all unknown parameters of the model be identical in the two samples. It is unlikely that such a constrained model would hold—since it is to be expected that the variances of the unmeasured constructs differ between populations, just as the variances of their indicators differ. The next highest level of the hierarchy might be one in which all structural coefficients of the model are constrained to be identical in the two samples. Since all of the estimated structural coefficients (α_{ij}, β_{ij}, and γ_{jj}) are relevant to the issues of either attitude stability or attitude constraint, if such a model fits the sample data the implication would be that both populations exhibit equal attitude stability and attitude constraint. At a somewhat lower level of this hierarchy, we might test models in which the three types of structural coefficients (α_{ij}, β_{ij}, and γ_{ij}) are constrained to be identical, one type at a time. For instance, a model in which all α_{ij} are constrained to be equal between the two samples tests whether the degree of attitude constraint is equal in the two populations. A model in which β_{ij} are constrained equal between samples, but in which other parameters differ, tests whether the issue-specific component of attitude stability is equal between populations. Likewise, a model in which γ_{ij} are constrained equal between samples tests for equality of ideological stability. There are many other levels in this hierarchy that we will not detail (for example, putting between-sample constraints upon some of the α_{ij} but not upon them all).

---

[3] While we must assume that U_{ij} is uncorrelated with T_j to estimate the coefficients of the model, we have constrained I_i to be uncorrelated with T_j on substantive grounds rather than because of requirements of the estimation procedure.

Differences in the quality of fit between two successive levels of this hierarchy can be tested by comparing the two χ^2 statistics that result from the estimated parameters. The difference between these two χ^2's is itself a χ^2 and can be used to determine whether the model in which fewer between-sample constraints are made fits the observed data significantly better than the more constrained solution.

We have earlier presented the rationale for avoiding between-sample comparisons of measures of association between standardized variables. Thus, we wish to estimate the structural coefficients of the model using the "raw" or untransformed metrics of the variables. To estimate these coefficients, we must fix the metrics of the unmeasured constructs. If we do not do so we will be unable to estimate their variances (Kenny, 1979). The metrics of latent constructs are fixed by constraining one structural coefficient between each construct and an observed variable at unity. Because we assume that the time-specific common factors (T_j) represent a general ideological predisposition, the structural coefficients or loadings (α_{ij}) of the three liberal-conservative questions on these constructs were constrained at unity for each year.[4] For the item-specific constructs (I_i) the structural coefficient of the 1972 question for each respective construct was constrained at unity.

RESULTS

Table 1 presents the means, standard deviations, and correlations among all fifteen variables for the elite group. Table 2 presents the same data from the nonelite sample. On all five issues, the nonelite group tends to have more conservative attitudes than the elite. Comparing the standard deviations across samples, the elites have more varied responses on the busing and general liberal/conservative attitudes, but less varied on the other three.

When we use the traditional assessments of constraint and stability to compare attitude structures in the two samples, results consistent with Converse's emerge. The average correlations between different items within the same year is .47 for the elite sample and .31 for the nonelite sample. Thus, the elites seem more constrained than the nonelites even though these latter show higher constraint than Converse's data from 1958, consistent with the findings of Nie et al. (1976). Assessing stability, the average within-item, between-years correlation for the elite sample is .64, while for the nonelites it is .51. Again, Converse's hypothesis

---

[4] In fact, the choice of which variable we use to set the metric of a latent construct is arbitrary so long as it is the same metric for all groups on all occasions.

seems to be supported, although more stability characterizes the nonelites' attitudes than in 1958. We turn now to our structural equation model to more properly test Converse's hypothesis.

Starting at the lowest level of the hierarchy of models discussed in the Methods section—the level at which no between-sample constraints upon the model's parameters are imposed—the obtained parameter estimates are presented in Figures 2 and 3 and Tables 3 and 4. The figures present the structural coefficients of variables on the time-specific common factors (α_{ij}), the structural coefficients between these factors or constructs (γ_{jj}), and their disturbances. Figure 2 applies to the highly educated or elite sample. Figure 3 presents the parameters for the nonelite sample.

Table 3 presents (for each sample) the loading coefficients of variables on the item-specific factors (β_{ij}) and the disturbance variance for each variable (U_{ij}).

* This negative disturbance variance probably indicates some misspecification in the nonelite model. However, the quality of fit of the model as a whole leads us to believe that this misspecification is slight.

Table 4 presents the estimated variances of all factors or latent constructs for each sample.

The structural model we have hypothesized with no between-sample constraints simultaneously fits the observed variance-covariance matrices of the two samples quite well, χ^2 (144) = 165.61; p = .105. Separate tests of the model, on each sample alone, confirm that the observed matrix does not deviate significantly from the model's predictions in either case (for the elite sample: χ^2 (72) = 80.07; p = .241; for the nonelite sample: χ^2 (72) = 85.54; p = .150). Thus, it appears that, for both samples, the attitude items at any one point in time exhibit a single common factor structure. Regardless of the degree of attitude constraint or stability in the samples, a single underlying attitude construct or ideology does an adequate job in explaining all of the covariance between specific attitude items at any given point in time. The quality of fit of the model therefore leads us to reject Converse's hypothesis that there is no single underlying ideological continuum that is reflected in the attitude responses of nonelite members of the electorate.

The degree of attitude constraint in the two samples is assessed by the relative magnitude of the α_{ij} coefficients, the structural coefficients of the time-specific constructs on the variables. To test for equal constraint in the two populations, every α_{ij} in one sample was constrained to be identical to the corresponding α_{ij} in the other sample. Within any sample the different α_{ij}'s were allowed to vary. Under these between-sample equality constraints, the estimated model inadequately fits the two variance-covariance matrices, χ^2 (156) = 198.87; p = .012. In other words, the departures of the observed data from the estimated model are significant. This conclusion is confirmed by examining the difference between this χ^2 and the goodness of fit of the model with no between-sample constraints: Difference χ^2 (12) = 33.26; $p < .001$. Thus, the model with each α_{ij} constrained to be equal between samples fits significantly less well than the unconstrained model.

While this informs us that the α_{ij} coefficients in the two groups are not identical, it is still possible that the two populations exhibit equal levels of attitude constraint across the five issues. That is, even though we cannot say that all α_{ij} coefficients in one group are equal to their counterparts in the other, it still may be the case that they have α_{ij} coefficients of relatively equal magnitude across all variables. In fact, this turns out to be the case. Examining the α_{ij} coefficients in the two samples from the unconstrained model portrayed in Figures 2 and 3, we see that

Table 4. Maximum-Likelihood Parameter Estimates; Elite and Nonelite Samples; No Between-Sample Constraints

	Variances of Latent Constructs							
	T_1	T_2	T_3	I_1	I_2	I_3	I_4	I_5
Elite Sample	.997	.996	.815	.910	.836	.045	.058	.416
Nonelite Sample	.521	.367	.859	.266	1.411	.437	2.754	.430

in the cases of five of the fifteen variables the coefficients for the elite group are greater than the corresponding coefficients from the nonelite group. The nonelite sample shows larger α_{ij} coefficients in seven of the fifteen cases. In the remaining three cases, the coefficients in both samples have been fixed at unity. The average α_{ij} coefficient for the elite sample is 1.17; for the nonelite sample, the coefficients average 1.31. From these coefficients it is clear that the elite group does not show higher attitude constraint than the nonelite group, even though we are unable to conclude that the structural coefficients relevant to the constraint hypothesis are identical in the two. Rather than the coefficients being consistently larger in one sample than in the other, it appears that differences between the samples concern the extent to which the responses to individual attitude questions are reflective of the underlying ideological construct. Responses to the first question, that concerning the busing issue, are more reflective of an underlying ideology for the elite than for the nonelite sample. On the other hand, the fourth question, concerning a federally guaranteed job, seems to tap the underlying ideology more strongly for the nonelite sample than for the elite.

As we argued earlier, there are two types of attitude stability to be assessed: stability in the underlying ideological construct (T_j) and stability in item-specific variance. The latter sort of stability is assessed by the β_{ij} coefficients, the loading coefficients of variables on the item-specific factors, I_i. The first step in testing this item-specific stability is to test a model in which each β_{ij} in one sample is constrained to be identical to the corresponding coefficient in the other sample. The parameters of the resulting model are found not to fit the observed variance-covariance matrices, χ^2 (154) = 188.7; $p = .030$. This model, with between-sample equality constraints upon β_{ij}, accounts for the observed data significantly less well than the model containing no between-sample constraints, difference χ^2 (10) = 23.10; $p = .01$. Thus, we must conclude that the coefficients that indicate the level of stability in item-specific variance are not equivalent in the two populations.

As we argued when discussing the α_{ij} coefficients and the attitude constraint issue, it may be that the two groups exhibit roughly equal item-specific stability even though we know that individual β_{ij} coefficients are not identical. If we ignore those β_{ij} coefficients that are fixed at unity to set metrics for the I_i constructs (all of the 1972 coefficients), we find in the unconstrained model that in five of the ten cases the elite sample shows higher β_{ij} coefficients, and in the other five the nonelite sample shows higher coefficients. Thus, it appears, once again, that while we know that the individual β_{ij} coefficients in the two samples differ, it is not true that these indicators of issue-specific stability are higher in the elite group than in the nonelite group as Converse (1964) would lead us to expect. It is interesting to note that, once again, the busing and guaranteed job issues are the two that consistently show between-sample differences in the degree of item-specific stability. For the elite sample, responses to the guaranteed job question exhibit higher item-specific stability than for the nonelite, while for the busing issue this finding is reversed. This pattern complements that which we found for attitude constraint. Those issues that for one sample reflect ideology less well show more item-specific stability for that sample than for the other.

The other sort of stability to be assessed in the two groups is the stability of the latent time-specific constructs (T_j), the underlying ideology. This ideological stability is operationalized by the γ_{jj} structural coefficients in the model. Just as we did with the α_{ij} and β_{ij} coefficients, we reestimated the parameters of the model under the specification that individual γ_{jj} coefficients be equal across the two samples. Just as we found for the between-sample constraints on the other structural coefficients, the respecified model with between-sample constraints on the γ_{jj} coefficients does not adequately account for the observed data, χ^2 (147) = 178.13; $p = .041$. This respecified model does a significantly poorer job than the model with no between-sample constraints in explaining the observed data, difference χ^2 (3) = 12.52; $p < .01$.

Knowing that the individual γ_{ij} coefficients in the two populations are not identical, we can examine their magnitude in the original model to compare the stability of the latent ideological construct in the two groups. In Figures 2 and 3 it can be seen that γ_{21}, the effect of T_1 on T_2, is larger in the elite than in the nonelite sample. On the other hand, γ_{32}, the effect of T_2 on T_3, is larger in the nonelite than in the elite sample. Finally, γ_{31}, the direct or unmediated effect of T_1 on T_3, is substantially larger in the nonelite than in the elite sample. While we must conclude that the ideological stability in the two samples is not identical, it certainly is not the case, as Converse (1964) would have us believe, that substantially higher stability is obtained among elite than among nonelite respondents.

The major difference between the two samples in the magnitude of the γ_{ij} coefficients lies in the values of the γ_{31} coefficients. The other two coefficients, γ_{21} and γ_{32}, seem to be quite substantial in both samples. On the other hand, in the elite sample the effect of T_1 on T_3 seems to be nearly totally mediated by T_2, while in the nonelite sample there exists a substantial unmediated effect of T_1 on T_3. To test whether, in fact, the difference in γ_{31} is the only difference in these ideological stability coefficients, the model was respecified to include between-sample equality constraints on both γ_{21} and γ_{32} but not upon γ_{31}. The resulting model does nearly as good a job in accounting for the observed data as the original model in which there are no between-sample constraints, χ^2 $(146) = 168.76; p = .096$. In fact, the quality of fit of the respecified model is not significantly poorer than the unconstrained model, difference $\chi^2 (2) = 3.15; p > .20$. In this respecified model, γ_{21} in the two samples equals .88, γ_{32} equals .82 in both samples, and γ_{31} equals .06 in the elite sample and .53 in the nonelite sample. Given that this respecified model accounts for the observed data as well as the original model does, and given that the difference in the γ_{31} coefficients in the two samples is substantially more than twice their pooled standard error (.18), it would seem that the nonelite population shows more long-term stability in its underlying ideology than the elite population. Interestingly, this difference in stability, running in the opposite direction from Converse's hypothesis, is due to the presence of an unmediated long-term effect of 1972 attitudes on 1976 responses in the nonelite group. For the elite group, the long-term effects of prior attitudes are totally mediated by the intervening attitudes.

One of the strengths of the present structural equation model for the study of attitude stability is that we are able to assess coefficients that are not attenuated by irrelevant sources of variance in the observed variables. In other words, in assessing the stability of the underlying ideological construct we have been able to remove extraneous variance (both random and systematic) from the indicators of that construct. Even though between-sample comparisons of standardized measures of association should not be made, it is informative to present the correlations between the latent ideological constructs in the two samples to illustrate how our usual measures of attitude stability, based on single indicators, are seriously attenuated. Table 5 presents the estimated correlations between the latent ideological constructs (T_j) from the model in which no between-sample constraints are made. The remarkable thing about these correlations is their magnitude. Across both samples, the correlations between the underlying ideology average .914 for two-year intervals. For the four-year interval, 1972 to 1976, the average correlation between the underlying ideology is .894. As we have seen from the structural coefficients, it is not the case that the nonelite group shows less attitude stability than the elite group. What is remarkable in this model is the degree to which both groups show extremely high attitude stability.

Table 5. Correlations Among Latent Time-Specific Constructs (T_j)

	Elite Sample	Nonelite Sample
ρ_{12}	.956	.840
ρ_{23}	.951	.908
ρ_{13}	.914	.875

DISCUSSION

The conclusions we have reached differ from those of Converse and his colleagues when they have compared elite and nonelite attitude systems. In fact, they differ from what our own conclusions would have been had we used the traditional analytic procedures (comparing average correlations). On the other hand, some of our conclusions are consistent with those reached by researchers critical of the Converse hypothesis (most notably, Achen, 1975). From our structural equation model, the following conclusions emerge:

(a) The attitude systems of both groups show a single common-factor structure at any one point in time. Thus, the data from both groups are consistent with the notion that there exists a single underlying ideological predisposition that is reflected in these specific attitude responses. This single underlying predisposition adequately explains all of the covariance between responses at any one point in time.

(b) There is no evidence of greater attitude constraint in the elite than in the nonelite sample when the relevant structural coefficients are compared. While the average magnitude of these coefficients does not differ in the two groups, there are differences between them in the degree to which responses to specific issues are ideologically derived.

(c) When comparisons are made between samples in the stability of issue-specific components of variance, there is no evidence of greater stability in the elite than in the nonelite group. While there is no difference in the average magnitude of the structural coefficients that indicate issue-specific stability, there are differences between the groups in the extent to which responses to different issues show issue-specific variance.

(d) Both groups show remarkable stability in their underlying ideological predisposition. When we compare the relevant structural coefficients, there is no evidence that the elite sample shows higher ideological stability than the nonelite sample. In fact, the only significant difference between groups in these coefficients is the presence of an unmediated or direct effect of 1972 ideology on 1976 ideology for the nonelite. The elite group shows no such effect.

In the introduction to this paper we discussed three methodological shortcomings in the traditional comparisons of attitude systems between elites and nonelites. Our solutions to these three problems are responsible, we believe, for the differences between our conclusions and those arrived at by the more traditional comparison methods.

Our first conclusion, that a single underlying ideological predisposition explains attitude covariance in both samples, differs from earlier researchers because we have explicitly tested the single common-factor hypothesis in each population. Other researchers have examined ideological predispositions by coding responses to open-ended questions concerning political candidates. It is a long inferential leap from the results of such coding to the conclusion that nonelites show no underlying ideology in their answers to specific attitude questions. Testing for a single common-factor structure in the covariances between such questions permits a much more direct assessment of the ideological basis of attitudes.

As we mentioned previously, a few other researchers have examined the factor structure of a set of attitude items to determine whether an underlying ideological dimension is used. Luttbeg (1968), for instance, concludes that neither elites nor nonelites show an underlying ideological dimension in answering the ten attitude questions that he analyzed. Rather, both samples showed evidence of five underlying factors. We suspect that the difference between our single factor solution and Luttbeg's multiple factor solution is due to the specific attitude questions examined. Luttbeg's questions concerned a variety of local issues that might not be expected to tap an underlying liberal-conservative ideological dimension (for example, whether a metropolitan park should be built; whether new industry should be attracted). The questions we examined, on the other hand, might be expected to relate much more strongly to an underlying liberal-conservative stance. Thus, we reach the not altogether surprising conclusion that the presence of an underlying ideological predisposition in answering attitude questions depends upon the content of those questions more than it depends upon respondents. In fact, Luttbeg agrees with us that no greater ideological use is shown by elites than by nonelites.

The second conclusion we have reached, concerning the equality of attitude constraint in our two samples, differs from previous research because structural coefficients were compared between the samples, rather than measures of association between standardized variables. To assure ourselves of this fact, the structural model we hypothesized was estimated with the variances of variables and unmeasured constructs fixed at unity. In this standardized solution, the factor loadings of variables upon the time-specific ideological constructs were found, on average, to be larger in the elite sample than in the nonelite. Thus, inappropriate comparisons of standardized measures of association have led, we believe, to the erroneous conclusion of greater attitude constraint in elite samples.

While there is no evidence of greater attitude constraint in one group than the other, we were unable to conclude that the relevant structural coefficients were equal in the two groups. This led us to the conclusion that individual issues seem to be ideologically based to differing degrees in the two samples. Thus the issue of busing seems to reflect underlying ideology more for the elite than for the nonelite, while a federally guaranteed job is a more ideological issue for the nonelite sample.

The two conclusions just reviewed, concerning the presence and the use of an underlying ideology, are clearly interrelated. Both argue that there is little difference in the use of ideology, across issues, between relatively educated and relatively uneducated respondents. Thus, as we argued above, variation in the use of an underlying ideology does not seem to depend upon respondents. The difference between our single common factor structure and Luttbeg's (1968) more complex structure suggests that different issues may affect the use of an underlying ideology. In addition, our evidence supports the notion that respondents and issues may interact in explaining variation in the use of ideology. While some issues are more likely to reflect an ideological construct than others, regardless of respondents, it is also true that there are systematic differences between respondents in the extent to which an underlying ideology is used to respond to a question on a *specific* attitude issue. Across issues, we may all, on average, be equivalent in the use of ideology; for any specific issue, we may vary in the extent to which we see it ideologically.

Our conclusions concerning attitude stability in the two groups are discrepant with some earlier conclusions (e.g., Converse, 1964) and consistent with others (e.g., Bishop et al., 1980). The degree of stability, however, particularly in the underlying ideological predisposition, is markedly higher than the stability shown by other researchers. This difference is due, we believe, to our success in separating ideological stability from item-specific stability. The common ideological factors which show such high stability are measured free both from item-specific variance and from random errors of measurement.

In addition to the magnitude of our stability estimates in both groups, the other interesting conclusion concerning attitude stability is the difference between samples in the size of the γ_{31} coefficient. That is, for the nonelite sample we found a surprisingly large unmediated effect of the 1972 ideological construct on the 1976 construct, while for the elite sample, the effect of 1972 ideology was nearly totally mediated by the 1974 ideological construct. Although his stability coefficients were much lower than ours, Converse (1964) reports a similar unmediated effect for his nonelite sample. The presence of such an unmediated four-year effect in the nonelite sample is inconsistent with relatively simple Markov chain assumptions concerning change. Converse (1964) has put forward two alternative models to account for these unmediated effects. Both models are based on the assumption that the direct effects over two years are fairly low. Since these two-year stability coefficients are quite high in our data, neither of Converse's models seem appropriate here. We have no simple theory to explain the presence of this unmediated four-year effect in the nonelite sample, other than to suggest the possibility that nonelite members think back to the last presidential election year (1972) in deciding their positions in 1976, while elite members do not.

In conclusion, we believe that our results pose a substantial threat to Converse's original hypothesis that the attitude responses of the public at large are unstable, nearly random responses. We have shown for a set of five attitude items that both the relatively educated and relatively uneducated members of the public show an ideological orientation that is remarkably stable over time. Attitudes of the public at large are both ideologically derived, if the issue is one on which an ideological perspective is useful, and quite consistent. Attitude researchers and policy makers who use public opinion polls should find some comfort in these conclusions.

COMMENT*

REJOINDER TO JUDD AND MILBURN

PHILIP E. CONVERSE
University of Michigan

Manuscripts reacting to the Belief Systems paper tackled by Judd and Milburn still cross my desk at the rate of better than a half-dozen a year. Only one in every three or four of these is published. However, whether published or unpublished, the verdict is certainly a mixed one, quite as these authors report; and my guess would be that if anything, disconfirmations are currently in the lead. In fact, I have seen so many disconfirmations in the past decade, and they form such repetitive patterns, that I consider myself something of an expert in the gambits necessary to produce disconfirmation. Invited to comment here, I thought it might be of some service to share these insights so that subsequent investigators can generate disconfirmations more surely and swiftly.

> (1) The first and foremost rule is to avoid data drawn from any genuine, national-level political elites, such as the American congressmen used in the original study. A chancy alternative is to substitute local elites, such as mayors and councilmen in small American cities, or members of Boards of Education almost anywhere. Safer yet is to carve a national cross-section sample into pieces, call the top end a political "elite," and use this different partition to disconfirm the original differences.
>
> (2) The preceding rule is, however, rarely sufficient in itself to ensure disconfirmation. A further precaution involves wise choice of the criterion variable separating a pseudo-elite from the non-elite, within a mass sample. We must remain credible, so, as Judd and Milburn point out, there are only two plausible contenders: education and political involvement. It has been known for many years (cf. Converse, 1975) that, as an empirical matter, education is a poor cousin in making this discrimination, compared with political involvement. Indeed, in the original text at this particular point (Converse, 1964: 229), even without the benefit of relevant data, the prediction was made in terms of "political interest," and not education. Hence, it is a good idea to avoid political interest, and hew to education as a discriminandum instead.

The questing reader has a right to complain at this point. After all, Judd and Milburn have observed not one but both of the above precautions, yet their raw data still confirm the original predictions rather than disconfirming them. How can this be? I myself am somewhat surprised, since I have seen data reported from several studies in which these two precautions alone are quite enough, especially with small N's. But the Pilgrim need not despair, since many other paths to disconfirmation have been mapped. The only problem is that these further paths require more extended explanation.

First, is a historical note. Upon my initial glimpse twenty years ago at the raw correlations between responses to the same political issue items in a national sample after a two-year interval, I was quite devastated. The possibility that all or even much of the observed turnover was true change seemed dim, and my psychometric training led me to regard these continuity correlations much as test/retest reliability coefficients. So construed, they indicated our measurements were extremely vague and unreliable. As I became more familiar with the data, however, a rather different message emerged. There was internal evidence that some respondents had answered some of our questions with very high reliability, while others had responded to the same items with very little reliability. These marked differentials fit very poorly with the conventional view of measurement reliability then prevailing, which was instrument-specific and assumed to be invariant in level over objects measured. I became convinced that these reliability differentials had to do with item-specific differences between respondents in cognitive states that were of high *substantive* interest.

I first described these differentials in item reliability in 1963, making the primary point that reliability had to be seen as a product of an interaction between measuring instrument and certain properties of the object measured (Converse, 1970:177). The paper contains my first "shot at" answering the key question as to the reasons for these reliability differentials. I opined that they stemmed from differences in what different respondents brought to the topic of each item in the way of information and attitude crystallization. When respondents brought a lot to a given subject, reliabilities would be high; for other respondents bringing much less to the subject, reliabilities would be lower.

After the 1963 paper I wanted further tests of the adequacy of these diagnoses. In particular,

I wanted to see if some population that was unquestionably long on information and commitment about such political issues would not respond to these items with much higher reliability than was found in the mass electorate, thereby certifying that the problem lay more with respondent confusion than with measurements that were intrinsically unreliable. The only data set filling this bill that was available to me was the Miller-Stokes interviews with American congressmen. These data were not ideal: the questions were not absolutely identical in wording for the two populations, and there was no panel or longitudinal component permitting a glimpse at anything resembling a test/retest coefficient, so that heightened reliability had to be deduced from the comparative behavior of internal consistency data (both of these practical deficiencies have been remedied in later mass-elite data collections with very gratifying results). Nonetheless, the differences were not only in the expected direction, but quite markedly so. Hence the 1964 paper addressed by Judd and Milburn was born.

I am no more prepared now than I ever have been to opine whether or not the cognitive differences I was discussing have effects beyond those that fall out when differences in actual reliabilities are appropriately isolated. It seems likely that there are further effects, although they are probably complex, and I have never had much doubt that the largest and most robust registration of these cognitive differences is in the differential reliabilities. This being so, the agile reader can spot another popular route to a disconfirmation:

> (3) Take the contrasting samples and correct the data from each for attenuation due to measurement unreliability, either by time-honored means or by the kind of "shucking off" into the measurement model that newer methods like LISREL invite. This almost certainly means that you clean out more measurement noise from the less informed sample than from the more informed one, but there is no need to make any point of that. What is important is that the adjusted data with the reliability differentials corrected away can be used to disconfirm the Converse expectation that such differentials between the samples will be found.

We lack space to develop at any length some of the other paths to disconfirmation that are invented and reinvented in these manuscripts. What many of them have in common is a certain confusion between aspects of the measurement operations I happened to use, and the actual underlying theory I was eager to evaluate. I apologized at the time (Converse, 1964: 238–9) for the marginal appropriateness of the correlational indicators I felt I must resort to. I was painfully aware of their sensitivity to variance differences, and assumed that in analytic situations where variance difficulties arose, such as Barton and Parsons (1977) encountered, investigators would hew to the theory and take intelligent evasive action by shifting to other indicators, just as Barton and Parsons did. But this is not usually so. For many (and particularly the critics) the theory is irretrievably embodied in this particular set of operations. Thus:

> (4) A variety of excuses can be found for tinkering with the variances between the comparative samples, and a shrewd choice of these adjustments can be very helpful in achieving disconfirmation. The most general-purpose excuse is that variance differences are measurement artifacts and substantively irrelevant. Few readers will think about the matter long enough to realize that in various measurement situations the theory itself predicts variance differences that are pregnant with substantive meaning which is destroyed when they are tampered with.

Similarly, it is easy to assume that the theory is nothing more than one monotonous prediction, to wit, that correlational indicators of constraint and stability will be high in well-informed populations and low in poorly informed ones. Actually, while this is indeed the customary expectation, I spent five pages in the original (1964) text discussing one large class of cases where the theory would predict an inversion of such an ordering. I have since thought of another large class of cases where an inversion would be expected. Hence:

> (5) Use the theory to locate an inversion of the normally expected order. Collect or find the relevant data. Assuming that they do indeed show the predicted inversion, publish them as a disconfirmation, since almost nobody thinks of the theory as more than the single prediction.

Perhaps this is enough of an arsenal to keep the disconfirmation mills busy for some time to come, although the reader who prefers to be original should remember that all of these have been used before in manuscript, if not always in print, and most of them a great many times.

By now it should be clear that I do not see the Judd-Milburn paper as a very challenging disconfirmation. Actually, I rather like the paper, once I read beyond the disconfirmation claims and a few of the amazing statements attributed to me. I am unruffled by the alleged disconfirmation, in part, because I know that far more incisive replications than this one can claim to be (see points [1] and [2] above), now completed in countries on three continents, show the predicted differences in a magnitude which completely eclipses the restricted ones appearing here.

I am also unruffled because I do not believe that this paper is a disconfirmation even in its own terms. That is, my minimal prediction calls for differences in measurement reliabilities between the two samples. Once a LISREL routine has crunched these data, where will I find the relevant evidence? Since reliabilities are indexed by proportions of error variance, I want to look mainly at the relative sizes of the disturbance terms estimated by the model. These are presented in the final columns of the Judd-Milburn Table 3. Given the natural metric used, the numerical magnitudes are meaningless to the casual reader. We should remain aware for what follows, however, that these error variances represent an embarrassing fraction of the total observed variances in these items.

It is also possible, given the natural metric, that we cannot make intersample comparisons without more information from the respective variance/covariance matrices. However, assuming the numbers would not be printed unless some sense can be made of them, I naturally note that, on the average, the absolute size of the error variances runs 20% greater in the noncollege sample than among the college graduates. These differences are not striking compared to real contrasts with genuine political elites, where figures run more like 200% than 20%. But they are in the right direction and should not be called a disconfirmation.

Actually, the authors do not call these vectors of disturbance terms a disconfirmation. In fact, they do not direct the reader's attention to them at all. Their discussions hinge on the rest of the estimates, which are, in effect, what remains with the differential unreliabilities analytically removed. This is the essence of the third disconfirmation strategy above.

In view of the rest of the authors' discussion, it is possible that we disagree profoundly as to the nature of reality out there. That is, I long have taken the low reliabilities which everybody agrees surround these attitude measures in the mass public to reflect a certain confusion that intuitively would seem warranted given the low levels of information about most of these subjects that everybody also agrees pertain in the public. To my eye, the authors obliterate these signs of confusion analytically and, then, turn around to proclaim proudly that no such confusion exists, at least not "really," for example, in the estimates from the structural model. I am not unaware of what this kind of "real" means. At the same time, I cannot forget how the data looked before the authors began to process them, and I am convinced that those raw data say something about reality out there, too.

HOW JEWS AVOID ALCOHOL PROBLEMS*

BARRY GLASSNER AND BRUCE BERG
Syracuse University

American Sociological Review 1980, Vol. 45 (August):647–664

Twenty-five years have passed since the last major study of Jewish drinking patterns. During that time Jews have drifted away from the Orthodox religious affiliations which the earlier studies (Snyder, 1958; 1978) found to be important in maintaining low alcohol problem rates, and yet these rates remain low. Data from a detailed study of Jews in an American community suggest a revised explanation that focuses upon four protective social processes: (1) association of alcohol abuse with non-Jews; (2) integration of moderate drinking norms, practices and symbolism during childhood by means of religious and secular ritual; (3) restriction of most adult primary relationships to other moderate drinkers; and (4) a repertoire of techniques to avoid excess drinking under social pressure. The results are discussed from the perspective of informal social controls.

If there has been a single well-documented and replicated finding in the sociology of deviance, it is the low rate of alcohol problems among Jews in comparison to other ethnic groups. Jews present high percentages of adult drinkers (Riley and Marder, 1947; Mulford, 1964; Cahalan and Cisin, 1968; HEW, 1972; Levy, 1973), but low alcoholism and alcohol problem rates (Snyder, 1958; 1978; King, 1961; Chafetz and Demone, 1962; Roberts and Myers, 1967; Room, 1968; HEW, 1972; Lowenthal et al., 1975; Schmidt and Popham, 1976; Greeley and McCready, 1978). The usual statistic given in recent years is that more than 7% of the adult United States population are alcoholics, but less than 1% of the adult Jewish population is so classified (Unkovic et al., 1975; 1977). Some researchers argue for a similarly low rate of alcohol abuse in Israel (King, 1961), and historical analysis suggests that alcohol problems have been rare in Jewish communities for the last 2,500 years (Keller, 1970).

However, two and one-half decades have passed since the last major sociological study of Jewish drinking patterns, and during that time an important change has occurred. Jews have drifted away from the Orthodox religious affiliations which the earlier studies (Snyder, 1958; 1978) found to be so important in producing low alcohol problem rates. "The noteworthy sobriety of the Jews appears to be primarily associated with the culture of Orthodox Judaism—a religious culture with a ritualistic emphasis, prescribing frequent drinking which is integrated with familial religious practices," Snyder (1978:96) contended. He joined Bales (1944) in predicting that the decline of Orthodoxy would bring the end of low Jewish alcoholism rates.

Since Jewish alcohol problem rates remain low, as suggested in the studies cited above, one turns to additional explanations of such rates amid the well-recognized (Lazerwitz, 1979; Heilman, 1977) diminution of Orthodoxy in contemporary American Jewish communities. Suggestions for such explanations have been available in the literature for many years.

Some theoretical constructions point, for instance, to special positions of the ethnic group in society. Glazer (1952) built upon Kant's (1789) argument that Jews are in vulnerable positions and that they respond with an emphasis upon self-control and propriety. "It is the consequences of the siege, passed down from generation to generation, and including such elements as the desire to hold on to one's senses and a distaste for the irra-

tional, that sets a limit to Jewish drinking," Glazer (1952:185) concluded. Similar arguments hold that Jews try to avoid the public censure that might arise from "affective" drinking (Glad, 1947), or that Jews have come to emphasize education and rational self-control (Snyder, 1978). Although this sort of discussion is descriptive of some Jewish value styles, it is by itself insufficient to explain low alcohol problem rates. Even if one is willing to grant causal power to values, the problem arises that these values somehow become substance specific. Jews do exhibit high rates of obesity and overeating (Patai, 1977: 447–53), high rates for neuroses and some psychoses (Wilkinson, 1970; Patai, 1977:447–53), and, within subpopulations, high rates of drug usage (Robbins et al., 1970; Patai, 1977:453–5).

What seem to be operative, then, are alcohol-specific protective characteristics in Jewish communities. Among those frequently cited are sacramental and family drinking (King, 1961; Snyder, 1978), which have depended, of course, upon traditional religious practices. (One must wonder about their continuation and vitality amid declines in traditional religiosity.)

A contrasting approach to the question of relatively low Jewish rates of alcohol problems seeks characteristics usually found among substance-abusing groups but absent from nonabusing groups.[1] Perhaps the best confirmed sociological generalization on this issue is that involvement with marijuana and alcohol is highly contingent upon usage of these substances by peers (Orcutt, 1978). If an explanation of Jewish drinking based upon this generalization is not to be "question-begging," however, it must address important issues. Do Jews, in fact, view members of their ethnic group as their principal drinking peers, rather than turning to peers from other walks of life, such as neighborhood, work or school friends? How could Jews maintain such peer relationships when other ethnic groups do not? Ample evidence suggests, for instance, that after the first generation in America, Italians (Lolli et al., 1958; Blane, 1977) and the Irish (Glad, 1947; Greeley and McCready, 1978) do accommodate to the drinking patterns of additional peers outside their own groups, even where ethnic group members cannot be properly termed assimilated at the structural or primary group levels. Indeed, Bales (1944), Snyder (1958) and Glatt (1973) all predicted both increasing acculturation of Jews and the expected concurrent increases in alcohol abuse.

In short, the development of an adequate explanation for the infrequency of alcohol problems among Jews requires a great deal of "unpacking" of social processes. The control of drinking needs to be approached directly—at one level to uncover within peer groups the actual means and content of socialization, inclusion and exclusion rules, relations with other groups, methods of boundary maintenance, and the day-to-day repertoire of substance-relevant behaviors. Similar questions might be asked at the level of the family as well, and here one might also identify the existence, or current content, of longstanding rituals, beliefs and symbolic associations. Such an analysis can help us to understand two phenomena: the group's actual drinking patterns, and the means by which the group aids its members in avoiding other drinking patterns available in the larger society. While some processes are productive of both phenomena, this article focuses primarily on avoidance.[2]

A recently emerging theoretical perspective that might be called the informal social controls approach entails this sort of analysis and incorporates well-confirmed hypotheses from the other perspectives. The general program is to identify two generic sets: (1) social controls that tend to prevent persons from passing through (2) a series of steps necessary in changing from one status to another. This approach is applicable to the variety of situations in which persons who are in many ways good candidates for a new status are prevented, at the primary groups level, from acquiring that status. Such situations include movement into educational, occupational, and deviant statuses. In the case of substance abuse, for the first generic set one seeks the general forms of regulating mechanisms available to groups in their dealings with substance usage, then tries to specify the sources and specific varieties of controls operative in a particular group relative to a particular substance. Similarly, to specify the latter set, one seeks the series of steps through which persons must pass in becoming substance abusers, together with any special content of these steps for a particular substance or group.

---

[1] Among those often listed are high levels of inhibited impulses and anxiety (Horton, 1943; Bales, 1944; Marshall, 1979), employment in jobs involving stress, power or challenges (McClelland et al., 1972), and anomie (Merton, 1957; Cahalan, 1970). However, even a casual look at Jewish communities would suggest the presence of these phenomena.

[2] Other reports in preparation deal with the following topics: Jewish drinking patterns, including amounts of alcohol consumed, attitudes toward drinking, and "social" vs. "need" drinking; a detailed discussion of methodology; and responses of Jews to heavy drinkers and alcoholics.

Relevant to the first generic set, a report from the National Research Council (Maloff et al., 1979) identifies, on the basis of a great deal of cross-cultural data, five types of informal controls on consumption: cultural recipes that describe which substances to use in which amounts to achieve which effects; other persons who teach when, where, how, why and with whom to use substances; rules specifying eligibility requirements for use (e.g., age, gender); sanctions that reinforce usage norms; and social relations that make it convenient or inconvenient to use substances in certain ways. Maloff et al. show that these controls function in varied ways among many groups and with regard to substances ranging from food to heroin. For instance, sanctioning may be accomplished by elders, by public officials, or by peers, and a sanctioning group may offer positive sanctions for one substance and negative for another. In all cases, however, the controls operate as traditions that are maintained through adaptation to historical, geographic and other situational conditions.

These controls restrict the availability or recognizability of the second generic set: the series of moves that several prominent studies suggest are necessary if a person is to use material objects for deviant ends. Whether it be money for embezzlement, or drugs or alcohol for problematic usage, crucial among the steps to deviancy appear to be (1) a redefinition of the person's problems as amenable to relief by use of the substance, (2) knowledge of how to use the substance in the necessary way, and (3) rationalizations to oneself and others in order to legitimize special usage of the substance (Cressey, 1953; Becker, 1963; Lofland, 1969; Orcutt, 1978; Maloff et al., 1979).

If an informal social controls view is sound, then a sociological explanation for low alcohol problem rates among Jews would seek to identify both the adaptations within this group of the generic informal controls on substance use and the way in which these control processes inhibit the three steps to substance abuse. In so doing, we may avoid the generalizability problems of group- or period-specific explanations (e.g., that Jewish drinking patterns result from Orthodoxy per se), and the potential question-begging in a plural society of group-nonspecific explanations (e.g., that peer drinking in general produces individual drinking).

The data reported below are from a three-year study that examined the drinking practices and secular and religious lifestyles of a scientifically selected random sample of American Jews. After describing the methodology, we report findings as to whether alcohol problems are actually rare among Jews. The remainder of the paper suggests an informal social controls view of how a Jewish community continues to avoid the moves toward alcohol abuse. We describe the learning, beliefs, social interaction patterns, and practical drinking strategies involved in maintenance of low alcohol problem rates.

METHOD

A stratified random sample was developed in a city of central New York that is consistently listed among the top few northeastern cities for market and social scientific research because it offers "mean demographics" on variables such as population size, ethnic composition, and age and income distributions. Estimates of the size of the Jewish population range from 8,000 to 12,000. To develop the sample required six months of negotiation with Jewish community organizations, many of whom were reluctant to allow their lists of names to be used for any purpose. Many separate lists from religious, social and secular Jewish organizations were utilized to construct a universe for sampling. These included congregational lists from five of the seven temples in the city, membership lists from nationally affiliated Jewish organizations, and a list of potential contributors to the local Jewish Welfare Federation. The latter list alone is reliably alleged to include the names of 95% of all Jews in the area and includes many unaffiliated ("secret") or nonpracticing Jews, who have been identified by Federation members. Through computer searches, duplicate names were eliminated and a random sample was generated. To this we added a random sample of Jewish students at the local university, produced by telephone screening of a random sample of the entire university student population. The students were added in light of estimates that 30% of the local Jewish community are university students, and in light of data suggesting that most Jewish youths attend college.

Potential respondents, in telephone contacts to set up appointments for in-depth interviews, were informed that the interviews would concern "lifestyle issues." The topic of drinking was not introduced during these requests for interview appointments. After considerable efforts we achieved a relatively low (9%) rejection rate (cf. Goldstein, 1964).[3]

In order better to compare subgroups which earlier studies have found to be important, we stratified the sample into equal cells of four persons each, as follows: young adult, middle age, and older; male and female; and Orthodox, Conservative, Reform and nonpracticing[4] subjective denominational affiliations. In so doing we were unable, despite hundreds of telephone calls, to fill the two cells for young Orthodox. The resulting sample consists of 88 Jewish individuals, representing 88 different families. Income distributions and education levels are similar to those of Jews nationally, except that our sample underrepresents the lowest income levels.[5]

The interviews were as extensive as we could make them. The schedule combined short-answer demographic questions with structured open-ended questions that encouraged respondents to discuss the issues fully. Many of the 144 scheduled questions were parts of series of planned "how," "why," "could you tell me more," and similar probes. Essentially our interview schedule used Snyder's (1958) as a developmental reference, in order to permit direct comparisons to his findings, but went into greater detail on

---

[3] A good deal is known about those who did refuse. Their reasons were lack of time or recovery from major surgery. Only two persons refused for other reasons ("invasion of privacy" in the case of a college professor, and fear of having answers recorded in the case of an elderly concentration camp survivor). Of those who refused for lack of time or recovery from surgery, we were able to determine that in the first case they did maintain regular and busy schedules, and in the other that they had been hospitalized.

[4] Nonpracticing Jews are taken to be those who describe themselves with that label, and includes persons sometimes called "secular," "Jews only by birth," or "inactive." All have in common that they see themselves as uninvolved in religious activities or organizations. To further ensure that we did not miss this group, we attempted snowball techniques, requesting that our early interviewees tell us in confidence of such persons they have identified in the community. None of the names mentioned, however, turned out to be absent from the original master list we had used for sampling purposes.

[5] Specifically, the median reported family income for 1977 is approximately $20,000, the range is $6,000 to $102,000, and the mean is $27,500. Converting our median income and that of the most recent national Jewish survey (Massarik and Chenkin, 1973) to standard (1967) dollars, median income for our sample is approximately $11,500, which is within a few hundred dollars of the national Jewish median. Eleven percent of our sample is in the highest income category reported in the national survey (17,000 standard dollars), compared to 8% nationally. On the other hand, our sample notably underrepresents the lowest income levels (3% below 5,000 standard dollars, compared to 19% nationally). The median and mean number of years of education for our respondents is 15, with a range of 6 to 22, and approximates the national sample's median of 14 years, and mean of 13.4. In a final item of comparison, 91% of our respondents are American-born, compared to 77% nationally.

"secular" topics. Thus, the schedule primarily emphasized issues regarding family life, thorough family and personal drinking history, religious practice, assimilation, feelings about ethnicity, attitudes towards drinkers and drinking, important life events, participation in Jewish communities, eating behavior, peer relations, and recreational activities. The interview was standardized to the extent that questions were presented to each respondent with the same wording and in identical order.

Ordinarily, interviews lasted 2 to 3 hours, with a range of 1½ to 3½ hours. Each interview was transcribed verbatim and coded by at least two independent coders. Only those responses about which the coders agreed and about which the respondent did not contradict himself or herself during the course of the interview are reported below as supporting our contentions.

There is considerable evidence within almost every transcript that the interviewer established good rapport and open, detailed discussions. It became almost commonplace, for instance, that the interviewer would be invited to dinner or invited to join the respondent's temple. Frequently, respondents would comment that they were offering more detail than they would give their own friends, or that they, as one respondent put it, "know what we should say, but that's not the way it is."

We are convinced that our familiarity with the research community, use of positive and negative wording on separated questions about key items, and friendly rapport amid extensive probing have paid off in valid, high-quality data. Undoubtedly, some respondents avoided some issues, but we doubt that many escaped very far from the net we cast.

Our sample and data are limited, however, in at least four ways. First, the 40+ hours required to sample, interview, transcribe, code and analyze an average interview, and limited funding, prohibited expanding the research to include interviews with family and friends of the respondents. Second, a desire to avoid giving respondents an opportunity to phrase "good" answers to sensitive questions restricted us to a single interview with each respondent. Third, the sample size and scheme (disproportionate stratification) permit only approximate estimates of percentage distributions.[6] Finally, respondents are all from one community. We tried to select a community of average size and in the region of the country where most American Jews live, but our findings may not generalize to some other locations, especially internationally or within the largest metropolitan areas. We accepted these limitations in exchange for intensive research opportunities and with the hope that future research will supplement ours.

JEWISH ALCOHOL PROBLEM RATES

Despite seemingly conclusive evidence within the literature cited in the first paragraph of this paper, we were frankly skeptical that Jewish alcohol abuse rates could be so low. We suspected that low alcohol abuse rates among Jews resulted more from the ability to hide excessive drinking and from the collection procedures of social scientists than from actual drinking patterns of Jews. We had each known an alcoholic Jew who managed to escape public detection. In addition, recent reports have argued that the Jewish alcohol abuse rate is rising (Glatt, 1973; Spiegel, 1978; Zimberg, 1976; *New York Times*, 1977; *Jewish Record*, 1977; Dropkin and Blume, n.d.[a]).

---

[6] Our equal cells turn out to be more closely proportionate, however, than might be expected, when compared to national Jewish samples. Our sample is divided into thirds by age groups, compared to these actual percentages nationally (of those of interview age, i.e., 15 years or older): 24% ages 15–24, 29% ages 25–44, and 47% 45 or older. The mean age in both our and the national sample (Massarik and Chenkin, 1973) is 35 years. Our sample consists of 27% each in nonpracticing, Reform and Conservative cells and 18% in Orthodox, compared to national sample estimates of 11% for Orthodox, 42% Conservative, 33% Reform and 14% nonpracticing (Lazerwitz, 1979). The sampling and coding procedures used in the national survey probably led, however, to undersampling of nonpracticing Jews. Sex distributions are roughly equal nationally and are equal in our sample. Thus, the most noteworthy disproportionalities in our sample appear to be an underrepresentation of persons 45 and older, and of persons with conservative religious affiliation.

We built into our methodology every technique we could find that would encourage full access to the extent of alcohol abuse in a Jewish community. The interviewer emphasized legal guarantees of absolute confidentiality. He was trained to conduct the structured interview as a conversation, by memorizing the schedule and undergoing extensive practice and pretesting sessions to work out segues, elaborate probes, and pacing. The interview schedule involved not only detailed drinking histories but challenging questions (e.g., "Who was the last alcoholic you knew?").

To our surprise, no member of the sample met the standard definitions of alcohol abuser (Kessel and Walton, 1965; Robinson, 1976; Glatt, 1970; Jellinek, 1960; National Council on Alcoholism, 1972). For instance, none has been intoxicated more than a few times, nor suffered social, economic or medical consequences as a result of drinking, nor could be said to be addicted to alcohol; and the heaviest drinker in the sample consumes fewer than ten glasses in any week. Of their Jewish friends and family members, only about one-fourth of the sample have ever even heard rumors of drinking problems, and in most of these cases the stories referred to distant relatives.[7]

A detailed analysis of drinking patterns within the sample will be presented in another paper. In the present context, 59% report having never been intoxicated, 23% report having been intoxicated only once or twice, and 18% report more frequent intoxication. In all cases these more frequent intoxication episodes were restricted to college or military years, or to special occasions such as weddings and Bar Mitzvahs. Of the full sample, 7% (all businessmen who drink at meals with clients) report one or more drinks per day, 5% (all Orthodox) are abstainers, and for the most part the remainder drink two or fewer glasses of alcoholic beverages occasionally. Seventy-six percent of those who drink mentioned alcohol use solely for social occasions, while the remaining 24% mentioned social drinking plus the occasional use of alcohol to relax.

In addition to our sample we solicited several key informants who occupy special positions, including rabbis, physicians, alcoholism counselors, a central figure in the regional Alcoholics Anonymous (AA) organization, and a city court judge—all of whom we interviewed solely about knowledge of Jewish alcohol abusers. All efforts turned up one unmistakable conclusion: Jewish alcohol problem rates in this community are very low. The highest number of alleged Jewish alcoholics reported to us came from a clinician who is dedicated to uncovering such persons. "There is an alarming problem with alcoholism in the Jewish community," he insisted. "I can name five alcoholics for you." All of the other key informants reported that there are not more than one or two Jewish alcoholics in this community.

Although one can easily imagine Jewish alcohol problems increasing in some places, the published reports have not established this. Most rely upon evidence that Jewish membership in AA groups is increasing in New York City and Los Angeles (*New York Times*, 1977; Dropkin and Blume, n.d.[a]; Spiegel, 1978). Our key informant from the AA regularly attends meetings throughout the central New York region and reports having seen one or two Jewish members in the decade she has been involved. In any event, an increase in AA membership may signal only an increase in seeking help, rather than an increase in prevalence of alcohol problems.

Much of the discussion of increasing rates depends upon speculation, as in Spiegel's (1978) allegation that there may be as many as 10,000 Jewish alcoholics in California's San Fernando Valley. We could locate only one study with any descriptive figures. Dropkin and Blume (n.d. [a],[b]) have been conducting searches throughout the New York City area to locate Jewish alcoholics for their sample. They report locating approximately 80 persons in the first four months, many of whom "traveled long distances to be interviewed," and that they are "far from having exhausted the supply." Given that approximately one million Jewish adolescents and adults live in the New York City area, even if the researchers locate one hundred times as many Jewish alcoholics as they had at the time of their report, the demonstrated Jewish abuse rate would remain less than 1%.

---

[7] None of this is to say that Jews do not buy or own alcohol. Indeed, the vast majority of homeowners in our sample boast of well-stocked liquor and wine cabinets. However, they also note either that these cabinets seldom require restocking, or that bottles are thrown out before they are empty. A nonpracticing businessman in his 40s:

> I have bottles and bottles of liquor that just have never been opened. Or things that have been opened that have never been touched through the years.

A Conservative college student in her teens:

> My father being a doctor, people just give him liquor. He says, "Another one?" For my brother's Bar Mitzvah we had over 200 people. We didn't even have to buy any liquor, just used the ones he'd been piling up.

The discussion about increasing Jewish alcohol abuse rates is of more than demographic interest. Not only is it being used to create more services for alcoholic Jews, but the existence of public claims of higher rates may actually help to increase the prevalence of alcohol problems within Jewish communities. This becomes evident upon examination of the first of four preventive social processes we located in the Jewish community.

FOUR PREVENTIVE PROCESSES

Our working assumption was that many factors combined to produce low alcohol problem rates among Jews, and we encouraged the several coders to find any evidence they could regarding approximately 50 hypothesized control processes that we expected to be operative. These included specific religious practices, various childhood experiences, emphases on self control, aspects of assimilation, distaste for alcoholic beverages, gender proscriptions, easy intoxication, peer affiliations, anxiety produced by drinking, styles of handling responsibilities and challenges, and general avoidance of drugs. We had also suspected that respondents suffered few stressful life events that would lead to alcohol problems, but found several histories of many events that respondents and others (e.g., Holmes and Rahe, 1967) found severely stressful, but without increased drinking. In addition, we informed the coders of our suspicion that still other processes, which we had not imagined, were also operative, and encouraged them to identify these within the transcripts. In the few cases where such additional processes were suggested by the coders, these were added to checklists used in coding the remaining transcripts, and previously coded transcripts were reexamined.

Against our expectations, only three of the processes we had anticipated, and one additional process (#1) uncovered during coding, were evident in more than a few of the interviews; but these four processes prove very powerful and in some cases subsume other processes. As will be noted below, the four appear regularly in the transcripts and put the Jew in a special lifelong relationship with alcohol. The protective social processes are as follows: (1) association of alcohol abuse with non-Jews; (2) integration of moderate drinking norms, practices and symbolism for oneself and significant others during childhood by means of religious and secular ritual; (3) continual reiteration of moderate drinking through restriction of most primary relationships to other moderate drinkers; and (4) a repertoire of techniques to avoid drinking more than one wants to drink amid social pressure. Together, these processes make it difficult for Jews to go through the moves listed at the beginning of this paper as necessary for deviant use of a substance. The four processes act as social controls that avert persons from redefining problems as amenable to relief by means of alcohol, learning to use alcohol to solve problems, or rationalizing such usage to themselves and others.

1. Alcohol Problems As Non-Jewish

The first protective process evident within our sample depends upon an assumption in everyday logic which holds that if one's group lacks a particular attribute, one must also lack that attribute. It depends as well upon a most basic sociological finding: that definitions of situations can structure situations (McHugh, 1968).

The fundamental point is Durkheim's,

that people control their consumption by referring to social norms that prescribe how much of a given substance people like them usually consume, and Sumner's, that members of groups contrast themselves with images of other groups. Within the Jewish community the belief system prescribes that extensive drinking is an outgroup characteristic, moderate drinking an ingroup characteristic.

The saliency of this belief is evidenced by 52% of our respondents telling us, although we did not even ask them about this issue, that alcohol problems happen to non-Jews.[8] When one excludes the college-age respondents, for whom we note in our discussion of the third protective process that the processes are generally inoperative, fully 69% of the remaining sample told us, without any stimulus from the interviewer, that Jews are not problem drinkers.

In most cases the respondents directly stated the association. An Orthodox counselor in his 60s:

> Nobody ever drank to get drunk. I mean that wasn't, isn't a Jewish concept. Liquor and wine is part of Jewish, you know, holiday and tradition. More sociability, at parties.

A Reform college professor in his 40s:

> [A friend] drinks a lot. I don't think he's an alcoholic, but his idea of socializing is to drink, so I buy a bottle of Scotch to have in the house, just in case, because he likes J&B. So when he comes over, I'll always offer him a drink. He and his wife are very drink-oriented people. They drink, and I associate that with non-Jewishness myself. I always associate Jewish tradition with food, as most people do, I think.

A Reform housewife in her 30s has long held this association:

> We were exposed to liquor plenty. Actually, my father worked for a beer company. It sounds like a stupid generalization, but non-Jewish people drink more heavily than Jewish people. That's a generalization I've been brought up with . . . and I still think it's true.

In some cases the association is apparent in less direct statements. A Reform housewife in her 50s:

> I've been a guest at [a local Jewish Country Club]. . . . You know, they never spend money on their bar there like they do in most Gentile country clubs.

Ours is a reconfirmation of the finding within earlier studies (Snyder, 1958:chap. 5; Kramer and Leventman, 1961). Indeed, Zimberg (1976) goes so far as to claim that "the sociocultural attitudes equating Jewish identity with sobriety are perhaps the major factors accounting for low alcoholism in Jews." That Jews define alcohol problems as not Jewish is customarily interpreted within the literature as one way in which the pious Jew maintains his sense of moral superiority (Snyder, 1978:162–9). Our data support this interpretation among the Orthodox, about whom the earlier literature concentrated, but verbalization of the belief is no less among other Jews in our sample, for whom it seems to be taken as a learned fact, as the above quotations suggest.

There are apparently three sets of experiences that make most of our sample accept the folk association of alcohol problems with non-Jews. First, the respondents indicate that eating is considered the Jews' naughty excess (a point discussed in the next section). Second, their own "fieldwork" leads them to accept the association. Only 13% say they know a Jewish person who might be considered a heavy drinker, and 78% say they find no evidence that alcohol problems could occur in their own families (in contrast to Dropkin and Blume's [n.d. (a)] sample of Jewish alcoholics, among whom 63% report a family history of alcoholism). Third, Jews see their own coping strategies as emphasizing rationality (Glazer, 1952). Explained a nonpracticing businessman in his 30s:

> [When] I run into a problem, something that I can't cope with, or tremendous excitement when we had the baby, I purposely didn't drink because I was going to lose control of myself. Or specifically when we had the baby I was so excited I didn't want to have any of my senses damaged, and I'm conscious of it at this point. When we get into some very sensitive business issues, or high

---

[8] The Yiddish expression is *shikker vie a goy* (drunk as a Gentile), usually quoted by our respondents as *shikker is a goy*.

> pressure times that occur during the year, I will purposely stay off it, only because I want to be as sharp as possible, and it does dull [you].

To the extent that defining one's group as nonalcoholic helps to prevent members of the group from becoming problem drinkers, recent campaigns promoting the idea that increasing numbers of Jews are alcoholics may, ironically, increase alcohol abuse. That the campaigns are having an effect is evident in several interviews. One finds questioning and confusion about the association between alcoholism and non-Jews among several of the younger respondents. A conservative professional student in his 20s:

> Traditionally in the Jewish community there's very little alcoholism. I'm convinced that is no longer true. The fact of the matter is that a number of congregations have opened up Alcoholics Anonymous chapters. . . . My family were never drinkers at all, and more and more people I know drink now. I still think to a certain extent it's a Gentile characteristic. From what I hear, there's a great difference between Jewish and Gentile celebrations. Jewish celebration is punctuated by the enormous amount of food service. From what I was told the Gentile idea of a party [as] being booze and pretzels still holds true to a great extent.

This first protective process thereby turns out to be two-sided. A recent newsletter quotes a psychologist's claim that "the Jewish alcohol abuser is . . . the most difficult to work with. They 'know' they don't exist. They believe they have the same reality as unicorns. This makes it very difficult for them to identify themselves as alcohol abusers" (Spencer, 1979). Other clinicians (Dropkin and Blume, n.d. [a], [b]) report that Jewish alcoholics use as a defense mechanism the definition of alcoholic as non-Jewish ("Since I'm Jewish, I can't be alcoholic").

Thus, on the one hand, the definition of alcohol problems as non-Jewish serves as an eligibility control that can contribute to avoidance of alcohol problems within the larger Jewish group by making more difficult the moves which we have noted are necessary for substance abuse. If extensive drinking is considered non-Jewish, it becomes more difficult for a Jew to believe that problems are solved through the use of alcohol, to learn how to use alcohol to solve problems, or to rationalize to significant others such deviant use of alcohol. On the other hand, for those Jews who despite the deterrents do find their way to alcohol problems, the Jewish community's definition can hinder the work of helping services personnel by promoting denial on the part of the alcoholic.

Needless to say, holding the definition of alcohol problems as non-Jewish cannot alone provide Jews with continuing moderation of drinking patterns. One's conception that a substance is undesirable (or "dirty") depends in large part upon respect for the conventions of one's groups (Douglas, 1966). These conventions are revealed not only by stories about how the group deals with the substance but also by the conduct of users. In fact, the very perpetuation of the definition of excessive drinking as non-Jewish depends upon the actual drinking practices of Jews—practices which reinforce either the truth or the falsity of the association. The first process of control depends upon the three additional processes, which together maintain moderate drinking practices. The four processes form what might be visualized as a fabric, with each strand depending upon the others.

2. *Moderation Practices from Childhood*

As noted at the beginning of this paper, Snyder (1958) argued that Jewish sobriety "depends upon the continuity and vitality of the Orthodox religious traditions." He emphasized the importance of Orthodox religious affiliation per se for his respondents, but also within his work one finds the possibility for extension of the protective characteristics of Orthodoxy. He argued, for instance, that "the thread of orthodox life may be woven into many regional fabrics without losing its sobering influence." Our data suggest that the protections have been extended even further, into the contemporary "secularized" community. Through religious and ceremonial usage of alcohol, Jews continue to learn "prescriptive" (Mizruchi and Perruchi, 1970) drinking norms. In contrast to the expectations of those authors (Zimberg, 1976; Malzberg, 1940; Bales, 1944) who expected the loss of traditional protections with the loss of Orthodoxy, we have detected a good deal of tenacity and adaptability of traditions and their latent symbolism.

Our data do confirm the drift away from Orthodox affiliation, as evidenced most dramatically by our inability to fill the cells for young Orthodox respondents. However, the data indicate that a vast majority of respondents' families continue to practice regular ceremonial and religious ritualistic practices that involve controlled drinking of alcohol. For instance, 89% of the sample celebrate Passover Seder, in which prescribed amounts of wine are consumed as part of a religious and historical service. Included in this group who hold Seders are 85% of the respondents who consider themselves "nonpracticing." In addition, 77% of the sample report that they attend Sabbath services at least occasionally, where wine is consumed as a religious rite and in many cases during the post-service gathering. Another indication of continuing traditions is the prevalence of the ritual *brieth* (briss) upon the birth of a male child, rather than a simple medical circumcision, even among our "nonpracticing" and Reform respondents. Also noteworthy is the pattern we found among the 10% of the sample in exogamous marriages. In each case there was evidence that the Gentile spouse had begun to foster Jewish customs and an identification with Jewish lifestyle, even if he or she had not formally converted to the religion.

In short, the Orthodox affiliations are generally absent, but children continue to have plenty of opportunities to learn to associate the drinking of alcohol primarily with special (dare we say "sacred") occasions (see Knupfer and Room, 1967:690). Currently met in new ways are the conditions Snyder (1978) listed on the last page of his book: "Where drinking is an integral part of the socialization process, where it is interrelated with the central moral symbolism and is repeatedly practiced in the rites of a group, the phenomenon of alcoholism is conspicuous by its absence."

Sobriety amid drinking continues to be the norm in Jewish homes. Our interviews suggest that Jews perpetuate this association and its connection with ritual, not only by affiliation with religious life but also by restricting drinking to special secular occasions, and by cataloguing drinking as a symbolic part of festive eating.

Almost without exception, our interviewees report that drinking in their homes during childhood was predictable, and drunkenness was never condoned or was condoned only on very rare occasions. A Conservative secretary in her 60s:

> Parents don't usually put a drink in front of themselves or their children. Mine didn't, and I wouldn't with my kids. Some kids will say, "You do it, why can't I do it?" We never did drink except for a special occasion.

A nonpracticing medical researcher in her 30s:

> It was a ritual in our daily life. It was a family routine. [My father] would sit and read the paper for a little while and have the drink and then we would have dinner and my mother would have a drink with him.

A Conservative college student in her teens:

> My parents do not drink, which I think is one reason why I don't drink, because I never really saw my father come in after work and drink. We'd have wine with dinner, if someone brought it over, and I think there was a bottle of white wine in the refrigerator.

Nearly half of the sample could not remember their first drink, but recall that all of their early drinking was during childhood, in the home as part of religious ceremonies. Of the remainder of the sample, 89% recall that their first drinks were recreational with their families, in the home or at the synagogue, and prior to the age of 13. Thus, only about 5% of the sample recall their first drinks as outside the family and later than childhood.

Our sample thus meets the conditions that several studies have found result in low adult alcohol problem rates: parents who agree about drinking norms for themselves and their children; formative drinking experiences within the family; and controlled drinking at an early age (Wilkinson, 1970; McGonegal, 1972). Jews are sheltered from what Pittman (1967) calls the ambivalent drinking culture of the United States, which consists of conflicting attitudes toward alcohol consumption. The Jewish family maintains instead what Pittman calls a permissive drinking culture in which drinking is permitted, but excessive drinking is not.

In addition, Jews receive an early advantage over many other ethnic groups by means of the main beverage served in the home and the form of introduction to this beverage. Most of the sample first tasted wine, and nearly the entire sample report that most drinking in their parents' homes involved wine. Thirty-one percent of those who have a preference list wine as their current favorite alcoholic drink, and another 44% name other sweet drinks (e.g., rum and coke, grasshoppers, screwdrivers) as current favorites. Virtually the entire sample drink wine more than any other alcoholic beverage. In contrast, and despite stereotypes of alcoholics as "winos," few alcohol abusers concentrate upon wine or sweet drinks (HEW, 1972), perhaps because these beverages become unpleasant in large quantities.

Our interviewees tend to drink only a glass or two of wine when they do drink, and they tend to view wine as quite apart from intoxicating alcohol, indeed as almost nonalcoholic. During an interview with a retired Conservative businessman in his 60s, the following exchange was recorded:

> Q: Did your mother ever drink with your father?
> A: My mother never drank.
> Q: Nothing? Not even wine?
> A: Oh, she drank wine, yeah. On occasions.

A Conservative retired salesman in his 70s:

> A: I don't drink at all.
> Q: You don't drink at all?
> A: Very seldom. I'll just have some wine.

These early drinking experiences probably proved protective by the form of the drinking, however, more than by the content of the drinks. Nearly all of the respondents recall that they were included as full participants on at least some regular occasions—given roughly as much to drink as were the adults. Lolli et al. (1958) note that Italians remember childhood drinking as part of a regular family, social or religious custom and display low alcohol abuse rates, while Italian-Americans recall a casual sip-taste and display higher rates of alcohol abuse.

Not only is Jewish drinking limited primarily to predictable family, social and religious occasions but also, as suggested above, the drinking is tightly connected with eating (cf. Hill, 1977). Most of the interviewees alluded to the relative importance of food over drink, and the absence of drinking without eating. A nonpracticing businessman in his 40s:

> I can remember more my mother arranging platters of cold cuts and potato salad or baking because she was having people [to the house] than I can ever remember her serving drinks. The emphasis was always on the food, and the liquor was deemphasized. If it was there it was because there were people who expected it to be there.

A Conservative social services administrator in his 40s was talking about what made him think that an acquaintance had a drinking problem:

> He did drink, and there is a difference between just drinking or having a schnaps or having wine with Friday night meal and the need to have a drink when there's no specific meal involved. That's my distinction, and he had a need to have alcohol for whatever his personality needs.

Several interviewees spoke as if they saw drinking as almost inseparable from eating. A Conservative schoolteacher in her 30s:

> Drinking has just never entered as an activity. It's part of a thing like eating. It's OK with foods. It goes, to me, it goes along with eating.

The moderating effect of associating drinking with eating was first noted by Feldman (1923) in a comparison of the contrasting practices of English Gentiles and English Jews. In recent decades several studies (reviewed in Plaut, 1967; and Zucker, 1976) have suggested that groups characterized by widespread drinking but few alcohol problems have integrated their drinking into a variety of basic activities. In the case of Jews, this integration is taken a significant step further, toward making drinking a symbolizer. Drinking serves as a symbolic punctuation mark that helps to separate certain good events (religious services, weddings, dinners, etc.) from all other events (cf. Mandelbaum, 1965). By being a symbolizer, the drinking takes on a symbolic character itself. However, owing at least in part to the emphasis on wine, a beverage that carries an almost nonalcoholic social meaning, and the association of excessive drinking with non-Jews, drinking has little chance of becoming substantive as well as symbolic, as among Irish men who demonstrate manhood by drunkenness or as among the Aztecs who seek intoxication in religious ceremonies. All of this adds up to avoidance by Jews of two of the moves involved in the deviant use of a substance: belief that problems can be alleviated through such usage, and learning how to use the substance to solve problems.

On the other hand, probably no sorts of childhood experiences can, on their own, protect a group from excessive substance use in adulthood, where so many experiences intervene. The two remaining protective factors maintain in adults the drinking patterns and associations they learned as children.

3. *Insulation by Peers*

Haer's (1955:180) conclusion—"the behavior of contemporaries, friends and spouse are much more potent in establishing drinking practices than the behavior of the previous generation"—has found continuing support (Orcutt, 1978; Greeley and McCready, 1978; Maloff et al., 1979). For the drinking patterns learned in childhood to be maintained, and for the self-definition of Jews as moderate drinkers to remain believable, Jews must collectively reiterate moderate drinking patterns in adulthood. This is accomplished in part through family practices, as we have already noted. However, the serious threat to moderate drinking occurs outside the home—at parties and other public occasions where considerable drinking is often encouraged or expected.[9]

Indeed, our data suggest two situations in which members of the sample radically increased their consumption and their instances of intoxication. Drinking rates during college and military service periods increased radically for at least one-fourth of those for whom the question applies. Several respondents report that nearly all of their intoxication experiences occurred during college or military service. These changes are evident for both males and females, and independent of the decade during which the respondent attended college. The only exception is the Orthodox, for whom drinking does not increase in college or in the military. As Snyder (1958) noted, the Orthodox seem to stay together during these experiences and maintain traditional views and practices.

A Reform veterinarian in his 30s told the kind of story we heard from nearly all of the relevant respondents:

> The only times I ever drank were in my junior year when we had a party at the [fraternity] house. You'd really get drunk, to the point where you got sick and everything. Everybody does that, every once in a while. That happened maybe twice a year. The only thing I ever had prior to that was a glass of wine. I didn't like beer, and never drank beer after college.

---

[9] Norms of usage and intoxication tend to vary as predictable functions of participation in peer groups using alcohol (Becker, 1963; Orcutt, 1978). One finds oneself in not one but in various contexts, each of which includes physical location and other persons in assorted interactions and combinations. "As people move from one social context to another . . . the environment suggests alternative codes of conduct" (Maloff et al., 1979). Thus, to be part of a moderate drinking culture may well be context specific. There is no prima facie reason why a Jew without drinking problems in one setting will be without these problems in other settings.

[10] Compare, for example, Maddox and Williams's (1968) finding among blacks:

> Heavy drinking is described as a common, socially institutionalized, culturally integrated means of narcotizing the drinker against the frustrations of a restrictive environment There is nothing distinctive in the notion that alcohol can be used occasionally to modify reality. Its significance here lies in the imputed legitimacy of heavy drinking as a way to "make out" in a hostile world.

Several interviewees became intoxicated for the first and last times in college, and they note the negative aspects of the experience. A nonpracticing saleswoman in her 40s:

> I used to consume more alcohol back in college. You'd have a party and people would drink and would get drunk. When I was first married I can remember giving a party and I got drunk, and I handed out towels to everyone, and I invited them to stay and ended up sitting in the bathroom sink and squirting everyone with shaving cream, singing "brush your teeth with Brill Cream [*sic*]." I woke up the next day, and I felt awful. I just kept calling everyone up and saying, "What [did] I say?" As I grew up I realized that I just didn't like the feeling.

More than tastes changed, however. Many respondents say that during college and military service they and other Jews tried to "fit in" through any means available, and that most of their friends were non-Jews. In contrast, almost without exception they report that after college and the military ("as an adult") they were less willing to "fit in" by means of activities they found unappealing.

Seventy-six percent of the sample report that all or nearly all of their friends are Jewish, although most say that their work associates are primarily non-Jews. The respondents are not, as a group, ideologically opposed to primary group assimilation, however. When asked if it matters whether they spend recreational time with Jews or non-Jews, 64% answered negatively, 25% affirmatively, and 14% (including two who answered affirmatively) described types of situations in which it would or would not matter.

Of the 24% of the sample who indicate that many of their friends are non-Jews, in most cases the discussions reveal mixed feelings about this state of affairs. A nonpracticing medical researcher in his 30s:

> I don't think it makes any difference, but I am aware of it. . . . When I meet a new person or when I hear a name it is always a thought. Oh, he's Jewish or he isn't, or with some women, I wonder if she's Jewish. So it's something I look for subconsciously, I would say, and that I'm aware of. . . . I identify myself as Jewish and so I identify, or I assume certain things about Jews that I don't assume about other people.

Several commented that it is unimportant to them whether a friend is Jewish or not, but that being with Jews is easier. Others suggested that some of their non-Jewish friends remind them of Jews. A conservative school teacher in her 30s:

> I think [my close friend] would like to be Jewish. I really do. Maybe that's part of what she likes about me. Her sister was married to a Jewish fellow and kids us that somewhere in her background there's gotta be a Jew because she likes Jewish foods.

The 76% reporting primarily Jewish friends tend to give a variety of reasons. Many persons of various ages and affiliations say they "just end up" with Jews, others indicate that they feel more comfortable with Jews, several older persons say they have a language problem and prefer to speak Yiddish or German, and some of the more religious members of the sample say they disapprove of various prejudices and moral practices of non-Jews. The majority of the sample who have primarily Jewish friends for the most part are no less certain about what attracts them to Jews than are the other respondents. In many cases we conducted considerable probing to obtain impressionistic answers, such as the following from a Reform housewife in her 30s.

> Most of my good friends are Jewish, my closest friends. One of my closest friends, though, is a girl who converted. And basically she converted, and is it. She is still—she's not Jewish. She's fun and everything else, but her values and feeling on certain things are definitely not Jewish . . . and a lot of times we discuss things she won't understand, because she doesn't come from the same background. . . . I seem to gravitate toward Jewish people. I just have a warmer feeling. A feeling of, I can't pinpoint it, but, just certain feelings.

The general gravitation toward Jewish things and people (90% see "Jewishness" as important to their lives) protects Jews from excessive drinking in obvious and not so obvious ways. Firstly, one is unlikely to find others who would encourage, cooperate with, or even condone excessive drinking. Thus, the rationalization of extra drinking, a necessary move if one is to become an alcohol abuser, becomes difficult. This is self-evident in those cases where Jews drink primarily among other Jews. The process goes further, however, to selection of non-Jews who drink like Jews (cf. Alexander and Campbell, 1970). A nonpracticing college professor in his 50s:

> Most people at the party were not Jewish, actually. This one guy was making a real ass of himself. He'd had too much to drink and it made everybody uncomfortable. I guess our friends just are not heavy drinkers. I mean, we carry drinks around at our parties, but when this guy got drunk he really stood out. . . . I think he eventually got the message, because he was one of the first to leave.

Staying with Jews and other moderate drinkers makes inconvenient or unavailable the use of alcohol to various substantive ends—in contrast to groups such as the Oaxacans, where intoxication provides persons with license to shout insults and attend social gatherings without invitation (Dennis, 1975). Jews who become intoxicated are more likely to derive only scorn or pity.

A net result of the moderate drinking environment is that Jews hold images of social interactions over their life spans that do not include much drinking. This point is evident, for example, in the case of an Orthodox businessman in his 40s who answered the question, "When did people drink when you were growing up?" with, "My family just didn't drink. People we are with now just don't seem to drink." Or the Conservative male college student who answered a question about parents' drinking patterns with, "My parents rarely drink at all. Myself, I went through the drinking phase with my friends, but we've turned the page now."

Group avoidance is thus a dynamic process. By modeling consistent group drinking practices and norms in adulthood, Jews perpetuate the drinking associations for the next generation. Also, because unique alcohol consumption practices serve to emphasize ethnic differences in this multiethnic nation (Cisin, 1978), adult drinking patterns contribute not only to perpetuation of the first protective process (defining drunkenness as non-Jewish), but also to group boundary maintenance and increased personal identification with Jewish attributes, even among Reform and nonpracticing Jews.

4. Avoidance Repertoire

Despite the social interaction patterns just noted, the drinking histories reveal that at least 46% of the sample have found themselves during adulthood under social pressures to drink more than they wish to drink. We noted several exchanges similar to the following with a nonpracticing businessman in his 40s:

> Q: Does it matter if others drink with you?
> A: No, it seems to matter more whether I drink with them.
> Q: What do you mean?
> A: My not drinking tends to make more people uncomfortable than their drinking makes me.

The drinking histories, symbolic associations, and uniformity of group opinion we have noted thus far seem to make these respondents generally unafraid to offer an assertive no when they are encouraged to drink more than they wish. When asked how they avoid excessive drinking under a variety of pressure situations, many respondents did not seem to understand why we thought such a situation might be a problem. They perceive their avoidance repertoire as nonaction. A Conservative housewife in her 40s:

> I don't care one way or another whether I have a drink. If everybody is drinking and I feel like having a drink I'll have a drink. If everybody is drinking and I don't want a drink, I don't drink.

Nevertheless, upon further probing, the respondents do reveal a variety of techniques used in such avoidance. Several report that they begin a party with a mixed drink, but refill the glass throughout the night with only the mixer (e.g., moving from gin and ginger ale to ginger ale alone). Other respondents report that their family as a unit will act to prevent unwanted drinking. Some tell of plans whereby the wife will reprimand the husband for drinking too much at a party, when actually he is still "nursing" his first or second drink. Other couples develop reputations for themselves as nondrinkers by making jokes, or by avoiding such situations. A Conservative teacher in her 30s:

> Our colleagues think we're weird, first of all because they don't understand that we enjoy being together as a family, and neither one of us, even when we are working, want to go out to "happy hour" with our faculty. We want to go home and see each other. We don't want to spend our Friday nights drinking with people at work.

During the Passover Seder service one is called upon to drink four glasses of wine. An Orthodox teacher in her 40s explained how the family avoids doing so:

> We don't fill the glasses to the top. We cheat. Whoever drinks, we fill it up. We don't really follow to the letter. We cheat a little bit. In my case, I don't drink at all. . . . I just moisten my lips—this is the best that I can do. You know, my head would get dizzy. I just don't like it.

Other respondents reported specific avoidance repertoires they had worked out for particular situations. For example, a Conservative photographer in his 40s told of problems he used to experience at weddings, where sometimes he was "on the verge of being hit because they felt I wasn't showing proper respect for the bride and groom by toasting them." This photographer reports that since those early years he has consistently utilized a series of "convincing lines," to indicate that he cannot drink while he is working. He couples this with an increased number of photographs during the periods of heavy drinking, "Being Jewish, your reflexes and everything else sharpen you, and that expedience staves off any future attempts for people to push drinks on you," he explained.

By consistently utilizing an avoidance repertoire one misses opportunities to learn the deviant uses of alcohol, which is one of the crucial moves in development of alcohol problems. Indeed, our respondents' avoidance techniques sometimes seem the obverse of the final move customarily undertaken by substance abusers. Rather than finding rationalizations for drinking, our respondents find rationalizations for *not* drinking.

CONCLUSIONS

Distinctive group-maintained patterns of eating and drinking often remain stable, despite acculturation and secularization of the ethnic group. Acculturation seems to bring radical changes in drinking patterns to those groups who lack traditional informal controls directed at the use of alcohol, and among whom intoxication can be viewed as useful in itself (Price, 1975). This paper has suggested that processes of control have a long history within Jewish communities and have adapted to changing times.

We have described four processes of informal control that appear regularly within a Jewish community. Perhaps other mechanisms also exist in Jewish groups, but these four together effect all of the generic controls noted earlier, from cross-cultural studies: recipes regarding which substances to use and to which effects; persons who teach usage patterns; rules of eligibility; sanctions that reinforce usage norms; and social relations making various usages convenient or inconvenient. They create an environment in which a person would find it difficult to go through the moves that are necessary for deviant use of a substance: belief that use of the substance can alleviate problems, knowledge of how to use the substance, and rationalizations to legitimize the deviant usage.

In short, the processes we have noted serve as informal controls which militate against moves toward alcohol problems, as follows: (1) Defining alcohol problems as non-Jewish begins the cultural recipe for moderate drinking and excludes the entire group from eligibility for regular intoxication, while minimizing the possibilities for seeing alcohol use as related to one's problems. (2) Drinking practices are learned in childhood primarily from one's family, with an emphasis on wine and exclusion of substantive use of alcohol (i.e., to other than symbolic ends).[10] (3) Moderate drinking and the association of alcohol with special occasions, and the association of drunkenness with outgroups is reinforced in adult peer groups through drinking with those who share these expectations and who punish or exclude others who do not. Such peers made it difficult to rationalize deviant drinking or even to learn such drinking practices. (4) A repertoire of avoidance techniques decreases the necessity to change one's drinking patterns amid temporary social pressures toward increased consumption, and thereby further contributes to evasion of opportunities to learn new uses for intoxication.

More generally, our research suggests some ways in which Jews, as they have become a more secular ethnic group, have managed to "secularize" and expand the traditions that Snyder (1958) found epitomized in the Orthodox Jew of the 1950s.

THREE PARAMETRIC TECHNIQUES FOR CONTINGENCY TABLE ANALYSIS: A NONTECHNICAL COMMENTARY*

MICHAEL SWAFFORD
Vanderbilt University

American Sociological Review 1980, Vol. 45 (August):664–690

This article presents a direct comparison of three "new" parametric techniques for contingency table analysis—linear probability, logit, and log-linear modeling. The comparisons are rendered as nontechnical as possible, so that those familiar with ordinary regression will readily see how each of these techniques is analogous to regression in cases where one variable is deemed dependent on the others. The paper highlights the availability of linear probability modeling, a technique which has been largely ignored by sociological practitioners despite some attractive features. It also describes eight common errors in published applications of log-linear modeling.

During the past two decades, the statistical technology for analyzing contingency tables has undergone tremendous development. Researchers trained in the use of nonparametric techniques have begun to find that their statistical tools are deemed outmoded and that log-linear models are now "in." However, efforts to master the new techniques—or merely to appreciate the nature of their advantages and shortcomings—are frequently frustrated by methodological articles which contain misleading examples or which leave the impression that the new techniques are quite unlike others which are already widely understood. Moreover, several sociological articles which might serve as illustrative applications suffer technical flaws. Even those articles which avoid such pitfalls often couch their descriptions of the findings in such obscure terms that readers cannot discern any compelling connection between statistical results and substantive claims. Consequently, many who could well utilize one of the new techniques—as well as many others who need to read articles employing these techniques—find them inaccessible for all practical purposes.

Whenever one of the variables of a contingency table is treated as a dependent variable, the new techniques bear such a close resemblance to ordinary regression that almost anyone with a command of regression should easily grasp their essentials.[1] Of course, this similarity has

I would like to express my gratitude to several individuals whose comments on an earlier draft of this article were very helpful: Glenn Firebaugh, Walter Gove, J. Richard Landis, Tony Oberschall, William Rushing, and an anonymous *ASR* referee. I am also grateful to Yvonne Bishop, Gary Koch, and Jay Magidson for their observations on certain issues. It goes without saying that none of the above scholars should be held accountable for the views expressed in this article.

[1] Log-linear modeling is flexible enough to handle a wide range of situations in which the data are not viewed in this fashion. Nevertheless, viewing one variable as dependent constitutes the single most common conception underlying *sociological*

long been perfectly obvious to mathematical statisticians as well as to sociologists who have read the seminal articles on this subject in statistical journals. Moreover, even the titles of two of Goodman's articles (1972; 1975) suggest the resemblance of some of his own work to ordinary regression.

Nevertheless, focusing on the relationship of the "new" techniques to ordinary regression provides a convenient framework within which to illustrate and compare contingency table analyses based on three alternative models—linear probability, logit, and log-linear—the first of which has rarely been used by sociologists, despite some attractive features. Also, it provides a useful context in which to evaluate several important flaws or shortcomings in applications of log-linear modeling published in recent years. Finally, the relationship of the techniques to ordinary regression deserves discussion if only because it is not fully understood by many. One of the most widely cited nontechnical introductions to log-linear modeling (Davis, 1974) stresses an application which is *dissimilar* to regression, and several authors (to be cited later) have followed its example under inappropriate circumstances.

LINEAR PROBABILITY MODELS

Ordinary regression is, of course, conceptually well suited for analyses in which a certain dependent variable is theorized to be the function of several independent variables, but it could not be properly invoked for analyzing contingency tables until recently. As is well known, categoric *independent* variables present no barrier to ordinary regression since one may dummy code them without violating any assumptions underlying regression. In fact, analysis of variance is, in most respects, equivalent to regressing an appropriate dependent variable on categoric independent variables (Fennessey, 1968), and multiple classification analysis (Andrews et al., 1967) is but another variation on this theme. Instead, the difficulty inheres in the categoric condition of the dependent variable. Roughly speaking, ordinary regression generates numerical predictions on an interval or ratio scale, but such numbers would usually be meaningless in reference to categoric dependent variables.

This generalization does not, however, apply to *dichotomous* dependent variables. If, say, 10 respondents disagree with some statement while another 30 agree with it, the weighted mean obtained when "disagree" is coded "0" and "agree" is coded "1" is .75—the proportion agreeing with the statement. Since the mean of a dichotomous variable coded in this manner is interpretable, a regression-like analysis constitutes a viable approach to analyzing the contingency table. In this circumstance, one can estimate how various independent variables affect the *probability* that cases will fall into a given category.[2]

However, a dichotomous dependent variable characteristically violates two assumptions underlying ordinary regression (ordinary least squares: OLS)—that the dependent variable should exhibit (1) constant variance (homoscedasticity) and (2) a normal distribution at each level of the independent variables. Ignoring these assumptions casts a shadow over both the efficiency of the estimated regression coefficients and the validity of the tests of significance.

This much is widely recognized. Considerably less-appreciated among sociologists is the fact that Grizzle, Starmer, and Koch (GSK) have developed some straightforward modifications to ordinary regression which permit one to proceed legitimately with a rather routine

---

analyses in which log-linear modeling has been employed, and this case therefore deserves special attention. Moreover, even for those whose ultimate aim is to understand more general applications, the special case in which log-linear modeling is analogous to regression provides a heuristically useful starting point.

[2] Some statisticians would stress that modeling probabilities (or logits and odds, to be discussed later) is fundamentally different than modeling individual events (Hildebrand et al., 1977). Such a distinction has not proven very fruitful in the analysis of the data soon to be presented. It goes without saying, however, that one should not employ the techniques described here if probabilities and odds are theoretically irrelevant.

analysis without violating such assumptions (Grizzle et al., 1969; Bhapkar and Koch, 1968; Johnson and Koch, 1971; Lehnen and Koch, 1974; and Reynolds, 1977a). Briefly stated, the GSK procedure simply makes use of a generalized (weighted) least squares (GLS) routine—an estimation procedure which has long been available for situations in which the assumption of homoscedasticity is violated; and it substitutes a statistically sound chi-square test of significance for what would be a questionable F-test. Regression analysis proceeds in much the same manner as it does with a continuous dependent variable, and the interpretation of the resulting coefficients is nearly the same as well.

The main features of the GSK approach are well illustrated by the following reanalysis of the data from the National Opinion Research Center (NORC) analyzed by Davis (1974: 201) in his introduction to log-linear modeling. As he presents them, these data from Schwartz's NORC study (1967) are cast in a four-way contingency table. Educational attainment is trichotomized; time and region are dichotomized. Thus, twelve (3 × 2 × 2) subgroups are defined (Table 1, cols. 1–4). Respondents are further classified according to whether or not they agreed that blacks should have equal job opportunity (cols. 6 and 7). For example, 52 of 258 (adult) southern respondents with only grade-school educations favored equal job opportunity in 1946. The proportion who agreed (.20) is recorded in col. 8.

Consider the two related hypotheses that (1) living outside the South increased the likelihood that one would favor equal opportunity but that (2) the magnitude of this regional effect diminished between 1946 and 1963. Given these hypotheses, education might serve as an important control variable. Highly educated people may be more prone than others to favor equal job opportunity; if so, regional differences might merely reflect the higher educational attainment of those outside the South. Similarly, any reduction in the regional difference over time might merely reflect that the educational attainment of Southerners gained on that of others during the 17-year period.

One way to proceed is to examine the regression of the proportion favoring equal job opportunity (J) on time (T), education attainment (E), and region (R), along with appropriate interaction terms. A statistically significant coefficient for region would, of course, lead us to reject the null hypothesis of no regional effect; a statistically significant coefficient for the time-region interaction would lead us to reject the null hypothesis of no change in regional effect over time.

Under one variant of the GSK approach, the data would be organized as in Table 2. The criterion[3] variable (col. 13) is the proportion in each subgroup who agreed that blacks should have equal job opportunity.[4, 5] The coding of the independent variables (main effects) and their interactions (Table 2, cols. 1–12) is explained in the notes to Table 2; such coding schemes have long been available for use in ordinary regression and analysis of variance (Kerlinger and Pedhazur, 1973; Evers and Namboodiri, 1978; Fienberg,

---

[3] The dependent variable is "attitudes towards equal opportunity." However, the quantities which are predicted by the model may take any of several forms—*proportions* agreeing that blacks should have equal opportunity, *odds* of agreeing rather than disagreeing that they should have equal opportunity, etc. These alternate forms are termed *criterion* variables to distinguish them from the *substantive* dependent variable, which remains the same no matter which criterion variable is used. Incidentally, many technical articles on this subject use the term "response variable" instead of "dependent variable."

[4] Note that the regression coefficients obtained from the grouped data in Table 2 are identical to those which would be obtained if one enumerated all 3,579 cases, coding the dependent variable "1" for respondents favoring equal job opportunity, and "0" otherwise—the common sense approach in ordinary dummy regression (Coleman, 1970). Tests of significance, however, would be inappropriate in this case. For comments on the effect of weighting on tests of significance, see Goodman (1975).

[5] This analysis assumes that *each subgroup* constitutes a representative sample of the entire *subpopulation* of individuals eligible for inclusion in the sample and that the observations for the various subpopulations are independent of one another. These assumptions will be met when appropriate probability sampling procedures are used. Also, it should be pointed out that the behavior of significance tests of the sort employed here is unknown when subgroups contain less than about 10 cases; ideally they should contain at least 25 cases (Lehnen and Koch, 1974:286–7).

1978). Suffice it to say, the effect coding in Table 2 represents the omitted category with a "−1," whereas dummy coding (more familiar to most sociologists) represents it with a "0." Both effect and dummy coding yield identical predictions, but the interpretation of regression coefficients based on the two systems differs slightly.

Table 2 presents a *saturated* model; that is, all possible main effects and interactions are included as predictors.[6] Note that the number of predictors (12) equals the number of observations to be predicted. Such a model always yields perfect predictions, but is unsatisfactory because it is not parsimonious: comprehending 12 regression coefficients is no easier than comprehending 12 observations. The saturated model would be expressed in equation form as follows:

$$P = \beta_1 + \beta_2 T + \beta_3 E_h + \beta_4 E_c + \beta_5 R + \beta_6 TE_h + \beta_7 TE_c + \beta_8 TR + \beta_9 E_hR + \beta_{10} E_cR + \beta_{11} TE_hR + \beta_{12} TE_cR , \qquad (1)$$

where P is the proportion favoring equal opportunity in a given subgroup; T, E_h, E_c . . . TE_cR are the 11 design variables defined in Table 2; β_1 is the regression constant; β_2 . . . β_5 are the main effects; β_6 . . . β_{10} are the first-order (two-way) interaction effects; and β_{11} and β_{12} are the second-order (three-way) interaction effects. Notice that one category of each independent variable has been omitted, just as in ordinary dummy regression. For instance, the lowest category of education is omitted; high school education is represented by E_h; college education is represented by E_c. The coefficient for the omitted category of a variable equals the negative of the sum of the coefficients for the other categories of that variable. For example, the coefficent for "lowest education" equals $-(\beta_3 + \beta_4)$. In other words, under effect coding, the sum of the effects is defined to be zero just as it is in analysis of variance.[7]

---

[6] One might hypothesize that the step between grade school and high school is about the same as the step between high school and college. If so, one could save a degree of freedom by treating education as a single variable, coding grade school "−1," high school "0," and college "1." Orthogonal coding for purposes of testing linear and polynomial trends is described by Winer (1971) and by some of the references cited in the previous paragraph. Alternative coding schemes may give rise to alternative saturated models.

[7] Under *dummy* coding, the coefficient for the omitted category would be zero, and the coefficients

Table 3 summarizes the effort to account for the observations with a more parsimonious model than the saturated model just described. The variables in each equation are enumerated in col. 2; the chi-square due to error for each equation is recorded in col. 4. (*Disregard cols. 5 through 8.*) The strategy employed involves testing whether the *errors* in prediction for each equation are statistically significant, in which case the model is said to provide a *poor* fit.[8]

Consider Model 1 first. The error under Model 1 (which includes only the regression constant) is analogous to the total (deviation) sum of squares in ordinary regression or the total sum of squares corrected for the grand mean in ANOVA. In other words, this is the variation which one would like to explain with the independent variables. As was pointed out in a previous paragraph, Model 2 (a saturated model) explains all of this variation—that is, it yields no error.

Models 3 through 10 represent the steps of a backward selection procedure aimed at discovering which terms of the saturated model can be eliminated without introducing statistically significant error into the predictions.[9,10] Model 3 eliminates only the two time-education-region interaction terms from the saturated design. The chi-square due to *error* generated by this restriction is a mere .9 out of the 1406.6 yielded by Model 1. (In other words, 99.94% of the error variation under Model 1 is explained by Model 3.[11]) Since this error is not statistically significant, the null hypothesis that there is no second-order (three-way) interaction in the population is not rejected. This implies that TE_hR and TE_cR may be excluded from all subsequent models.

Model 4 eliminates all first-order interaction terms as well. In this case the chi-square due to error is so large (35.4, 7 df) as to require that the null hypothesis be rejected. Therefore, at least one of the first-order interactions must be retained in the final model. Models 5–10 reveal that the only first-order interaction terms which can be eliminated are E_hR and E_cR.[12] The chi-square due to error for Model 10 is only 2.1, which with four degrees of freedom is obviously nonsignificant, bespeaking a good fit. Thus, the final model includes a constant, main effects, and the TR, TE_h and TE_c interaction terms.

The excellent correspondence between the observed proportions and the predictions under Model 10 may be seen by comparing cols. 8 and 11 in Table 1. Notice, incidentally, that the largest error is found where the fewest cases are concentrated—in subgroup 11. This tends

---

for the other categories would provide comparisons with the omitted category rather than the unweighted mean. (See Kerlinger and Pedhazur, 1973:chap. 7.) In keeping with my ultimate aim, I have purposely omitted subscripts *i, j, k* and *l*, which would normally appear in equations presented in this paper. Given the coding in Table 2, this should not result in any confusion.

[8] When hypotheses are developed ex post facto, one should make adjustments to compensate for capitalizing on Type I errors. See Fienberg (1978), Haberman (1978), and Kerlinger and Pedhazur (1973) for comments on how to make these adjustments. As usual, the most desirable approach is to state one's hypotheses in advance.

[9] In the effort to settle on an acceptable model, one may instead use forward selection, examine the coefficients of saturated models (Goodman, 1971:45), or study the standardized residuals (Haberman, 1978).

[10] Even trivial effects may be statistically significant when sample sizes are large. Under these circumstances, one might well make better sense of the data by omitting substantively trivial interactions from one's model.

[11] It must be emphasized that "variance explained" in this context means something fundamentally different than it does in ordinary regression and ANOVA (and for this reason Goodman's efforts [1971] to come up with a figure comparable to multiple R in ordinary regression do not seem very useful). In contingency table analyses such as those described in this article, individual variation within cells is not included in the total variation to be explained. This has the effect of eliminating an important component of what would be considered error variance in an individual-level analysis. Therefore, the variance explained in contingency table analyses is invariably higher than in ordinary regression analyses of individual-level data. In fact, it is always possible to explain all the (between-cell) variance by including enough interaction terms (though such models are usually uninteresting by virtue of their lack of parsimony). This implies that even a "perfectly fitting" model of a contingency table would not explain the behavior of individuals perfectly.

[12] Notice that all interactions of a kind are treated as a unit. For example, either both education-region interaction terms are included in each model or both are excluded.

1963 × Other	−.04	.01				
6. TE interaction						
1963 × grade school	−.01	.01				
1963 × high school	.03	.01				
1963 × college	−.02	.01				

Note: Based on Model 10 in Table 3.

[a] The coefficients for 1946 and 1963 may be obtained from those based on the entire sample. See Kerlinger and Pedhazur (1973:251–60).

[b] Notice that identical predictions are obtained from the dummy-coded and the effect-coded equations. For example, the prediction for college-educated people in the South in 1963 is .85 (.80 + .10 − .05) according to the equation in col. 4; likewise, it is .85 (.62 + .23 + .00) according to the equation in col. 6.

to be the case because the procedure weights each observation (proportion) by the *inverse* of its binomial-based variance, and the *smaller* the number of cases on which a proportion is calculated, the larger its variance.

As in most regression analyses, the question at hand requires that one focus on the regression coefficients (Table 4, col. 1), not merely on tests of significance. In this case, the hypotheses would lead one to pay particular attention to the effects of region. The algebraic difference between the coefficient for South (−.09) and Other (.09) is .18. This may be interpreted as follows: living outside the South, rather than in it, raised the probability of favoring equal job opportunity by .18, controlling for time and education.

However, the statistically significant time-region interaction term indicates that the regional effect just mentioned changed between 1946 and 1963. Therefore, it is useful to write separate regression equations for the two time periods (Kerlinger and Pedhazur, 1973: 251–6). Notice that the algebraic difference of the regional coefficients is .26 in the 1946 equation, but only .10 in the 1963 equation (Table 4, cols. 3 and 4). Notice, also, that if dummy rather than effect coding had been employed, precisely the same message would have been carried by the regression coefficients (cols. 5 and 6).

Finally, the answer to the questions which gave rise to this contingency table analysis may be stated as follows:

> In 1946, living outside the South (rather than in it) added .26 to the probability of favoring equal job opportunity (controlling for educational attainment).[13] By 1963, this regional effect had dropped to .10.

LOGIT MODELS

Logit modeling closely parallels linear probability modeling. For our purposes, there is only one essential difference to bear in mind: instead of using the *proportion in category 1* as the criterion variable, it uses the logit—*the natural logarithm of the odds of falling into category 1 rather than category 2* of the dependent variable (Bishop et al., 1975: 22–3). In the NORC data analyzed above, for instance, among adult Southerners with only a grade school education in 1946, 52 agreed that blacks should have equal job opportunity while 206 did not agree (Table 1, cols. 6 and 7). The odds of agreeing, then, were 52:206, or (in reduced form) .25:1 (col. 9). The logarithms of the odds (the *log-odds* or the *logits*) appear in Table 1, col. 10.

---

[13] As in ordinary regression and path analysis, the estimates of effect may be biased if the model is improperly specified—that is, if the equation omits variables which both correlate with at least one independent variable and affect the dependent variable.

Readers may find it instructive to begin by comparing the conclusion in the previous section with that based on the logit model soon to be developed in this section:

> In 1946, living outside the South (rather than in it) added 1.14 to the logit of favoring equal job opportunity (controlling on education). By 1963, it was adding only .66 to the logit.

As will be demonstrated later, this finding may be restated in everyday language as follows:

> In 1946, living outside the South (rather than in it) multiplied the odds of favoring equal job opportunity by 3.13 (controlling on education). By 1963, this factor had dropped to 1.93.

The equation underlying a saturated logit model of the NORC data is as follows:

$$\begin{aligned}\ln(\Omega) = {} & \lambda_1 + \lambda_2 T + \lambda_3 E_h + \lambda_4 E_c + \lambda_5 R \\ & + \lambda_6 TE_h + \lambda_7 TE_c + \lambda_8 TR \\ & + \lambda_9 E_h R + \lambda_{10} E_c R + \lambda_{11} TE_h R \\ & + \lambda_{12} TE_c R\,, \qquad (2)\end{aligned}$$

where Ω is the odds of favoring rather than opposing equal opportunity; λ_1 is the regression constant; $\lambda_2 \ldots \lambda_5$ are the main effects; $\lambda_6 \ldots \lambda_{10}$ are the first-order interaction effects; λ_{11} and λ_{12} are the second-order interaction effects; and T . . . TE_cR are defined in Table 2. Notice that the form of this equation matches that of Equation 1 except that the criterion variable here is the logit. The λ's are regression coefficients which serve the same function as the β's in Equation 1.

Unsurprisingly, then, logit modeling can be conducted in the same manner as linear probability modeling. The data are again organized as in Table 2, except that the logits (Table 1, col. 10) serve as the criterion variable. The effort to find a parsimonious model proceeds with the same logic as before (refer back to Table 3, cols. 1, 2, 3, *and* 5). Again, it turns out that the only interaction terms which can be eliminated are E_hR, E_cR, TE_hR, and TE_cR (Model 10). The correspondence between the observed and predicted logits may be seen by comparing cols. 10 and 13 of Table 1.

As was the case in the previous section, the hypotheses at hand require that one examine the regression coefficients associated with the logit model (Table 5, col. 1); the TR interaction again renders it useful to write separate equations for the two time periods (cols. 3 and 4); and, of course, the coefficients based on dummy coding (cols. 5 and 6) carry precisely the same message as those based on effect coding. The two coefficients for region (1.14 and .66) appear in the illustrative conclusion at the beginning of this section.

It is possible to transform equations for the logit so that the results are instead stated in terms of odds. If one sets each λ_i in Equation 2 equal to $\ln(\gamma_i)$, every term in Equation 2 is given in terms of natural logarithms. At this point, one may take advantage of three mathematical principles: (1) if $x=y$, $e^x=e^y$; (2) $e^{\ln(x)}=x$; and (3) $e^{\ln(x)+\ln(y)}=x \cdot y$. By applying the exponential (antilog) function to both sides of Equation 2, the following multiplicative equation is obtained:

$$\begin{aligned}\Omega = {} & \gamma_1 \cdot \gamma_2^{T} \cdot \gamma_3^{E_h} \cdot \gamma_4^{E_c} \cdot \gamma_5^{R} \cdot \gamma_6^{TE_h} \cdot \gamma_7^{TE_c} \cdot \gamma_8^{TR} \\ & \cdot \gamma_9^{E_hR} \cdot \gamma_{10}^{E_cR} \cdot \gamma_{11}^{TE_hR} \cdot \gamma_{12}^{TE_cR}\,, \qquad (3)\end{aligned}$$

where Ω again represents the odds of favoring equal job opportunity rather than opposing it; γ_1 is a constant; the other γ's are main and interaction effects; and the exponents T . . . TE_cR are the design variables defined in Table 2.[14] (See

---

[14] Most people, including Goodman, write the design variables in Equation 2 (T . . . TE_cR) as superscripts rather than as multiplicands. This practice obscures the relationship between Equation 2 and Equation 3 and it masks the similarity between Equation 2 and Equation 1.

Table 5. Coefficients for Logit and Multiplicative Models of the NORC Data

	Logit Model		Logit Model Effects Coded		Logit Model Dummy Coded		Multiplicative Model Dummy Coded		Logit Model from Log-Linear Equation[a]	
	(1) Coefficients	(2) S.E.	(3) 1946	(4) 1963	(5) 1946	(6) 1963	(7) 1946	(8) 1963	(9) Coefficients	(10) S.E.
1. Constant	.62	.06	−.27	1.51	−1.32	.32	.27	1.38	.64	.06
2. Time (T)										
1946	−.89	.06							−.91	.06
1963	.89	.06							.91	.06
3. Education (E)										
grade school	−.67	.07	−.48	−.86	.00	.00	1.00	1.00	−.69	.07
high school	.02	.07	−.13	.17	.35	1.03	1.42	2.80	.00	.07
college	.65	.07	.61	.69	1.09	1.55	2.97	4.71	.69	.09
4. Region										
South	−.45	.05	−.57	−.33	.00	.00	1.00	1.00	−.45	.06
Other	.45	.05	.57	.33	1.14	.66	3.13	1.93	.45	.06
5. TR interaction										
1963 × South	.12	.05							.12	.06
1963 × Other	−.12	.05							−.12	.06
6. TE interaction										
1963 × grade school	−.19	.07							−.21	.07
1963 × high school	.15	.07							.13	.07
1963 × college	.04	.07							.08	.09

Note: These coefficients are based on Model 10 in Table 3. The multiplicative model coefficients may be used as follows: In 1946, among high school graduates outside the South, the odds of favoring equal opportunity, instead of opposing it, were (.27 * 1.42 * 3.13) = 1.174 (see Table 1, col. 9).

[a] Disregard cols. 9 and 10 until after log-linear modeling has been discussed.

Goodman, 1972:35.) In Equation 3, the coefficients estimate how changes in the independent variables *multiply the odds* of falling into category 1 rather than category 2, holding other variables constant. The coefficients of the multiplicative model which is equivalent to the final logit model above are contained in cols. 7 and 8 of Table 5, and the notes to that table illustrate how to use them. Notice that the multiplicative effect for region in 1946 (3.13) equals $e^{1.14}$, where 1.14 is the corresponding coefficient in the logit model (col. 5). The multiplicative effects for region appear in the second illustrative conclusion stated at the beginning of this section.

Technical explications of logit modeling appear in Theil (1970), Ashton (1972), and Plackett (1974). Further comparisons between linear probability and logit modeling will be set forth later.

LOG-LINEAR MODELS

Log-linear modeling, *as it applies to situations in which one variable is considered dependent on others*, is easily understood in terms of the approach just outlined. It proceeds with the same logic and arrives at the same conclusion as logit (or multiplicative) modeling. In other words, the results of the log-linear analysis which is about to be described virtually match those stated at the beginning of the previous section.

Log-linear models derive their name from the fact that they predict the *logarithm* of a certain quantity using a *linear* combination of predictor variables. In this sense, even logit models such as Equation 2 might be termed "log-linear."[15] However, the most general saturated log-linear model for the NORC data is given by the following equation:

$$\begin{aligned}\ln(F) = {} & \lambda^*_{13} + \lambda^*_{1}J + \lambda^*_{14}T + \lambda^*_{15}E_h \\ & + \lambda^*_{16}E_c + \lambda^*_{17}R + \lambda^*_{2}JT \\ & + \lambda^*_{3}JE_h + \lambda^*_{4}JE_c + \lambda^*_{5}JR \\ & + \lambda^*_{18}TE_h + \lambda^*_{19}TE_c + \lambda^*_{20}TR \\ & + \lambda^*_{21}E_hR + \lambda^*_{22}E_cR + \lambda^*_{6}JTE_h \\ & + \lambda^*_{7}JTE_c + \lambda^*_{8}JTR + \lambda^*_{9}JE_hR \\ & + \lambda^*_{10}JE_cR + \lambda^*_{23}TE_hR \\ & + \lambda^*_{24}TE_cR + \lambda^*_{11}JTE_hR \\ & + \lambda^*_{12}JTE_cR\,, \end{aligned} \tag{4}$$

---

[15] See Haberman (1974:313) and (1978:292).

where F is the frequency in a given cell of the full table (Table 1, cols. 6 and 7); J, T . . . JTE_cR are design variables calculated in the same manner as those in Table 2; and the λ^*'s are regression coefficients whose interpretation will be discussed shortly. The utility of writing the subscripts (1 . . . 24) out of sequence will become apparent to those who read the Appendix.

Equation 4 is a regression equation; its coefficients can be estimated with regression techniques (Grizzle and Williams, 1972; see also Haberman, 1974). Nonetheless, one peculiarity sets it apart from virtually all regression equations which have appeared in sociological literature: *it has no substantive dependent variable*. Unlike the proportions and logits considered above, the criterion variable in Equation 4 is not associated with any of the four substantive variables. In fact, "attitudes towards equal job opportunity" (J)—the *dependent* variable in the hypotheses at hand—appears in 12 of the 24 terms on the *predictor* side of the equation.

Nevertheless, as Bishop (1969) has demonstrated, there is a close relationship between log-linear and logit modeling. The logit modeling described in the previous section necessarily takes for granted the associations observed among *independent* variables, just as ordinary regression does. As will soon be illustrated with the NORC data, when log-linear modeling is conducted so as to include all observed associations among independent variables, the resulting log-linear equation includes the coefficients of a logit model closely related to Equation 2. More precisely, as is demonstrated in the Appendix, when Equation 4 is utilized to predict the logit of favoring equal job opportunity (J), those terms which do not involve J drop out, and the following equation results:

$$\begin{aligned}\ln(\Omega) = {} & 2\lambda^*_1 J + 2\lambda^*_2 JT + 2\lambda^*_3 JE_h \\ & + 2\lambda^*_4 JE_c + 2\lambda^*_5 JR + 2\lambda^*_6 JTE_h \\ & + 2\lambda^*_7 JTE_c + 2\lambda^*_8 JTR \\ & + 2\lambda^*_9 JE_hR + 2\lambda^*_{10} JE_cR \\ & + 2\lambda^*_{11} JTE_hR + 2\lambda^*_{12} JTE_cR\ , \quad (5)\end{aligned}$$

where $\ln(\Omega)$ is the logit of favoring equal job opportunity, and the other terms are defined as above.

Equation 5 corresponds closely to the logit model given in Equation 2. The J in Equation 5 always equals unity and can therefore be ignored in comparing the two equations[16]; and $2\lambda^*_t$ in Equation 5 equals λ_t in Equation 2. Thus, *to obtain the coefficients of a logit model from an appropriate log-linear model, double the coefficients of those terms in the log-linear equation which involve the (substantive) dependent variable, and disregard the others*.[17] For example, two times the coefficient for J *in Equation 4* equals the regression constant *in Equation 2*; two times the coefficient for JR equals the main effect of R on the logit of J; and two times the coefficient for JTE_cR equals the TE_cR interaction in an equation for the logit of J.

On this basis, log-linear modeling in situations where one variable is considered dependent on others can be illustrated with the NORC data. The models described in Table 3, col. 8 represent the steps of a backward selection procedure equivalent to the one in col. 2, employed above in logit and linear probability modeling. Model 1 includes only the regression constant of a logit model; recall that the regression constant is derived from the coefficient for J in a log-linear model. Model 1 provides a measure of the error variation to be explained with independent variables and their interactions (col. 6). Model 2 is the saturated model in Equation 4, with only those terms involving J stated. Model 3 eliminates the highest-order interaction on the logit of J without introducing significant error. Model 4 eliminates all but the main effects of T, E, and R on the logit of J; the null hypothesis is rejected. Models 5 through 10 test which interactions can be omitted without rendering the chi-square due to error statistically significant. Once again, Model 10 is clearly the best.

---

[16] The question at hand concerns the logit or odds that a respondent *agreed* that blacks should have equal opportunity. This is represented by J=1. If, instead, one wanted the logit or odds that a respondent *disagreed*, J would always equal −1.

[17] Under certain circumstances, it is not necessary to double the coefficients. See Gokhale and Kullback (1978:113).

Log-linear models are rarely represented as in Table 3, col. 8. Instead, symbols such as those in col. 7 are utilized. To avoid confusion, bear in mind two facts about these symbols. First, when, say, JER is enclosed in parentheses, the model includes not only the three-way interaction JER, but also all lower-order effects involving the same variables: JE, JR, ER, J, E, and R.[18]

Second, notice that all the log-linear models *include* (TER). This fact might be perplexing to readers who recall that TE_hR and TE_cR were *omitted* from most of the logit and linear probability models considered in previous sections. In reality, however, there is no inconsistency. Bear in mind that it is the *J*TER term in a log-linear model which corresponds to the TE_hR and TE_cR terms in a logit model, and that JTER is omitted from Models 3 through 10 (Table 3, col. 8) just as TER was omitted from the logit and linear probability models described in col. 2. The (TER) term is automatically included in all log-linear models in this analysis because doing so takes all the observed associations among independent variables for granted, just as in ordinary regression. Thus, the inclusion of (TER) is of no substantive significance.

The coefficients for log-linear Model 10 are presented in Table 6. As is illustrated in the notes to Table 6, these coefficients can be used to predict the *cell frequencies* in Table 1, cols. 6 and 7 (see cols. 16 and 17). However, the hypotheses in question require that one focus, instead, on the logit model which can be derived from this log-linear equation. As was stated above, the coefficients of such a logit model are obtained by doubling the coefficients of terms involving J (preceded by asterisks in

* Terms preceded by an asterisk are relevant to a logit model. Other terms merely account for the exact number of cases in each subpopulation. (Note that, because (TER) is included in the log-linear model, the number of cases predicted for each subpopulation (Table 1, cols. 16 and 17) equals the observed number (Table 1, col. 5).

Example: To estimate the cell frequency for Southerners with a grade-school education who agreed that blacks should have equal opportunity in 1963, first estimate the log of the frequency using the coefficients above. $\ln(F) = 4.549 - .417 + .213 - .481 + .321 + .116 - .059 - .344 - .226 + .456 + .067 + .059 - .105 + .051 = 4.20$. $e^{4.20} = 66.69$. Therefore, the predicted frequency is 66.69 (Table 1, col. 16; the discrepancy is due to rounding error). The observed frequency was 71 (col. 6).

---

[18] Some authors use different symbols to indicate the distinction between the three-way effect JER and the family of effects (JER): JER, JE, JR, ER, J, E, and R. For example, many would use J*E*R instead of (JER). Others do not bother to make the distinction. It turns out that (JER) or J*E*R is a convenient symbol because most log-linear modeling is hierarchical: high-order effects such as JER can only be included if lower-order effects involving J, E, and R are also included.

Table 6). These coefficients are presented in Table 5, col. 9, where they may be easily compared with those calculated in the previous section (col. 1). Since the coefficients are quite similar, the substantive conclusion of this log-linear analysis is virtually identical to the one presented at the beginning of the section on logit modeling. The coefficients are not all identical because the GSK procedure employed in the previous section was based on generalized least squares, while the log-linear modeling in this section was based on maximum-likelihood estimation. This difference will be treated further in the next section.

The *automatic* inclusion of (TER) in all the above log-linear models is the subject of some controversy. Unlike ordinary regression, log-linear modeling is flexible enough to test null hypotheses about the associations among independent variables—except, of course, if the observed associations are artifacts of one's sampling design.[19] As is explained in the latter portion of the Appendix, the derivation of Equation 5 does *not* depend on taking the associations among independent variables for granted. Bishop (1969) would take advantage of this fact. She would test those associations among independent variables which were not affected by the study design and drop the nonsignificant ones. Doing so would increase the precision of the estimates, she argues. Presumably this is the case because fewer predictors leave more degrees of freedom to the error variation. She would still interpret the coefficients as effects on the logits; for example, two times the coefficient for RJ is the effect of region on the logit of favoring equal job opportunity, controlling on other variables in the equation.[20]

Fienberg (1977:80) has suggested another reason why one might omit appropriate nonsignificant interactions among independent variables: doing so may relieve the computational problems caused by empty subgroups which frequently arise when several polytomous independent variables are cross-classified. For further advice on this subject, see Fienberg (1977) and Haberman (1978).

However, many other competent statisticians argue strongly for including the associations among independent variables, even when the statistical assumptions of general log-linear modeling do not require it (Goodman, 1972:38; 1973b; 1979b; Gokhale and Kullback, 1978:114; Haberman, 1978:chap. 5). Taking these associations for granted (that is, including them in the model) insures that the number of respondents in each subgroup is reproduced. Consider, for example, the cell frequencies predicted in the above log-linear analysis (Table 1, cols. 16–7). It was predicted that 195.31 respondents would agree, while 13.69 would disagree, in subgroup 12. These numbers sum to 209.00—precisely the number of respondents who were actually in this subgroup (col. 5). If the (TER) term were not included, the predictions would not generally sum to the observed frequencies in each subgroup. Such a model would end up predicting not only the logits in each subgroup but also how many respondents were in each subgroup. Most researchers, however, would find the latter predictions utterly irrelevant to the theoretical questions which motivated their research. In short, including the interactions among independent variables renders the equation fully comparable to regression. Another advantage of including all the interactions among independent variables is that doing so allows one to calculate the unexplained variation in the criterion variable, as in Model 1.

The above explication of log-linear modeling has focused on contingency tables in which one variable is considered dependent on others—a perspective which pervades contemporary sociological analysis. It must be emphasized, however, that log-linear modeling can handle a host of research questions which do not adopt this perspective. In the *statistical* literature on log-linear modeling, it has been more common for hypotheses to focus on the independence or conditional independence of variables without stipulating causal priority. For example, the fact that Model 10 (Table 3) includes (JTR) but not (JT*E*R) implies that (JTR) was not conditional on E in the population. (More precisely, the null hypothesis that the joint distribution of T, R, and J is independent of E is not rejected.) Similarly, the "T" in the (JTR) term implies that RJ, the association between region and attitudes towards equal opportunity, *was* conditional on time (within each level of education).[21] Further illustrations of this approach will appear later, in a critique of Davis's (1974) analysis of the NORC data. See also Hauser et al. (1975) and Stolzenberg and D'Amico (1977), Spilerman and Miller (1977), and Stolzenberg (1977). How to interpret log-linear models in terms of independence and conditional independence is discussed by Goodman (1970), Bishop et al. (1975:33–4; 45–7), and Haberman (1978:198–207; 259–61). Some other innovative applications of log-linear modeling which fall outside the scope of this paper may be found in Goodman (1969; 1979a), Duncan (1979a; 1979b), and Schuessler (1978).

---

[19] How sampling design affects the range of legitimate log-linear models is considered later.

[20] This point was confirmed in a telephone conversation with Bishop. She does not deal with the interpretation of coefficients in her article.

SOME COMPARISONS

It is useful to begin by reviewing some excerpts from the conclusions which were yielded by each of the techniques just outlined:

(1) living outside the South added .26 to the probability of favoring equal job opportunity in 1946 (controlling on education);
(2) living outside the South added 1.14 to the logit of favoring equal job opportunity in 1946 (controlling on education); and
(3) living outside the South multiplied the odds of favoring equal job opportunity by 3.13 in 1946 (controlling on education).

The first conclusion was derived with linear probability modeling; the second, with logit modeling. Whether the logit model was obtained directly (with the GSK technique) or indirectly (with log-linear modeling), the conclusion remained virtually the same. The third conclusion is mathematically equivalent to the second; the exponential function was employed merely to give the coefficients an interpretation as effects on the odds rather than on the logits.

Logit models have a distinguished history in statistics and are quite commonplace in biological assay. However, most sociologists are far more at ease with such concepts as *probability* and *percentage difference* than with *logit*. One might well expect, then, that linear probability modeling would be the most popular of the above techniques for analyses in which one variable is considered dependent on others. However, it has seldom been used in the discipline of sociology (Giles et al., 1976; Rushing, 1978). Among the reasons for this is that many sociologists believe that log-linear modeling is more statistically respectable than alternatives. With few exceptions, however, sociological articles on this subject have not compared log-linear modeling with the most sophisticated alternatives for contingency table analysis, but rather with ordinary regression using a statistically illegitimate dummy dependent variable (Goodman, 1975; Knoke, 1975; Gillespie, 1977).[22] Naturally, log-linear modeling comes out on top statistically in such a comparison. However, such comparisons are for the most part irrelevant in this case.

Before dwelling on differences between the techniques described above, it would be well for us to review the many similarities between them. First, they are all based on regression equations (1, 2, and 4). True, the general log-linear model (Equation 4) is fundamentally different from others in that its criterion variable is not substantive. Nevertheless, it *is* a regression equation, and it can be utilized to derive yet another regression equation (5) which does have a substantive criterion variable. However, though all of the above techniques amount to regression, ordinary regression cannot be utilized to calculate estimates without doing violence to assumptions about the dependent variable. In the relatively new parametric techniques described above, statisticians have given us procedures for estimating regression coefficients which are appropriate despite the fact that the criterion variables exhibit heteroscedasticity and a nonnormal distribution. They have not, however, even pretended to offer a radical new conception of how to analyze tables in which one variable is considered dependent.

---

[21] The expresssion "within each level of education" is an important part of the interpretation. As will be explained later, investigators frequently misinterpret terms such as JR as zero-order associations or as partial associations controlling on only one of the other variables in the table.

[22] This is not to suggest that Goodman was unaware of the existence of the GSK technique; also, Gillespie does focus on some shortcomings of log-linear modeling in his article.

This, then, suggests a second similarity. The above techniques all yield statistically respectable estimates—BAN estimates (best asymptotic normal). The sampling distributions are understood well enough so that confidence intervals can be calculated (based on the assumption of a very large sample size). In this respect, they are superior to their nonparametric predecessors. Consider, for example, the results of an analysis using gamma: in 1946, the partial gamma between region and job bias (controlling on education) was .52; by 1963, it had dropped to .30. Such a nonparametric analysis does not allow one to estimate the precision of the estimates nor (equivalently) to test the null hypothesis that there was no difference over time.[23] The new techniques, on the other hand, permit rigorous tests of interaction.

Another advantage which all the techniques share is that their coefficients are interpretable as precise measures of effect, whereas nonparametric measures of association usually are not. Consider, for example, a literal statement of the meaning of the partial gamma presented in the previous paragraph: errors in predicting whether or not people favored equal opportunity in 1946 are reduced 52% (from chance level) when information on region is taken into account (controlling for education). In this sense, gamma is a measure of proportional reduction of error, not an estimate of effect. One is not misled by gamma, but one does not end up with a conventional measure of effect.

Still another advantage which all three share is that they permit comparisons of the effects of independent variables. For instance, one can easily compare the effects of education and region in the final linear probability model (Table 4, col. 5): in 1946, the direct effect of having completed college rather than just grade school was to raise the probability of favoring equal opportunity by .25; this was about the same as the direct effect of living outside the South (.26). A more common approach is to compare the variation explained by each independent variable. However, this can be misleading.

Yet another similarity which deserves mention is that, in the above analyses, all the techniques yielded models containing identical main effects and interaction terms (Table 3, Model 10). This is not always the case. However, it is often the case because the criterion variables (logits and proportions) correlate highly with one another when most of the proportions fall between .25 and .75 (Goodman, 1975; Fienberg, 1977:22). In the NORC data, the correlation is .97 (between cols. 8 and 10 in Table 1). If more of the proportions had fallen at the extremes, the interaction terms in the final models might have differed somewhat from one another. This, in itself, would not imply that either model was superior in the sense of being closer to the "truth"; rather, it would merely reflect the fact that modeling proportions is not synonymous with modeling logits.

Finally, in a negative vein, it should be pointed out that the techniques are similar in their inability to handle continuous independent variables. Further comments on this issue will be set forth later.

Now let us consider three differences between the techniques. One salient difference involves the method of estimating coefficients. The coefficients of linear probability models and also of logit models tested with the GSK technique must be estimated with generalized least squares (GLS), while those of log-linear models (and of logit models derived from them) may be based on maximum-likelihood estimation (ML).[24] The importance of this difference remains to be demonstrated, however. True, Grizzle, Starmer, and Koch (GSK) (1969:502) did once acknowledge that their GLS coefficients might have less precision than ML estimates, and Goodman (1971:60) was quick to point out this admission in comparing his log-linear approach with their approach. However, as was pointed out above, as samples become large, the GLS and ML estimates in question take on the same properties (BAN). Furthermore, Grizzle and Williams (1972:139–40) have more recently argued that each of the estimation procedures enjoys certain advantages over the other, and they have adduced limited evidence to the effect that their GLS estimates are as good as ML estimates based on small samples. It appears that one should not take for granted the superiority of ML estimates without further evidence. And even if one *were* to establish their statistical superiority, it would not necessarily follow that the magnitude of superiority would make any practical substantive difference. One must also take into account other differences in deciding which technique to employ in a given situation.

---

[23] There *are* conventional tests of significance of *zero-order* gammas. Also, the GSK technique itself can be used to obtain estimates of the standard errors of numerous measures of association and partial association: gamma, Yule's Q, Kendall's tau$_b$ and tau$_c$, Somer's D, and Goodman and Kruskal's tau's (Kritzer, 1977).

It is, in fact, easy to illustrate how restricting oneself to ML estimates (because of their alleged superiority) might do injustice to one's analysis. Among sociologists, the most widely distributed computer program for log-linear modeling (Goodman's ECTA), while producing ML estimates, restricts analysis to hierarchical modeling (see fn. 18).[25] The emphasis on hierarchical models is usually explained by the fact that ML estimates for nonhierarchical models are more difficult to calculate than those for hierarchical models (Haberman, 1978) and because they are often difficult to interpret substantively (Bishop et al., 1975). However, it would be a mistake to presume that only hierarchical models of contingency tables deserve consideration. Suppose, for example, one wished to treat the trichotomous variable "education" in the NORC data as if it exerted a linear effect on the logit or probability of favoring equal opportunity. Under this circumstance, one might let "−1" represent elementary education; "0," high school education; and "1," college education. One might also calculate interaction terms by multiplying education as coded here times other independent variables. Such a model might well prove useful in analyzing sociological data. However, it does *not* correspond to a *hierarchical* log-linear model (Haberman, 1978:303–5).[26] The GSK procedure, as well as other techniques based on GLS estimation, can routinely test this and a wide range of other models. This, then, provides an example of how the alleged statistical advantages of ML estimates might be offset by other considerations.

A second important difference between the techniques concerns their criterion variables. The range of the criterion variable of logit models is unrestricted. In other words, the log of the odds (logit) is free to vary between negative and positive infinity. In contrast, since the proportion of cases in a given category of a dependent variable cannot logically fall below zero nor above 100%, the range of the criterion variable of linear probability models logically is restricted to [0,1]. The significance of this difference is that linear probability modeling might produce out-of-range (illogical) estimates, while logit modeling cannot. Advocates of logit modeling consider this a major advantage of their approach to contingency table analysis. However, the importance of this fact should not be overestimated. Linear probability modeling seldom produces out-of-range predictions in practice. To wit, a reanalysis of most of the published tables appearing in sociological articles listed below (under "References") resulted in no such predictions in the best models. Generally, such predictions are most likely to occur when one has a small sample and some of the population parameters fall near either zero or unity (Johnson and Koch, 1971:440). In the event that one did obtain an out-of-range prediction, one could modify the GLS estimation procedure to eliminate such predictions or one could of course resort to another model.[27]

---

[24] The GSK technique is capable of producing log-linear models with GLS estimates.

[25] Goodman's ECTA may be obtained for a nominal fee by writing Leo Goodman at the University of Chicago. Jay Magidson (Abt Associates Inc.; 55 Wheeler Street; Cambridge, MA 02138) has just begun to market a program which, although based on Goodman's technique, permits nonhierarchical modeling and nested designs. (See Magidson, 1976). Other well-known programs for log-linear modeling include C-TAB and MULTIQUAL, both available for a substantial fee through International Educational Services; Box A3650; Chicago, Illinois 60690. See also Haberman's program (1979:571 ff.). Routines for the log-linear analysis of contingency tables are also under development for eventual inclusion in SPSS (Statistical Package for the Social Sciences). Finally, GSK's program (GENCAT) may be obtained for a fee from J. Richard Landis, Department of Biostatistics, The University of Michigan, Ann Arbor, Michigan 48109.

[26] Hierarchical modeling *can* handle orthogonal coding. For example, a four-category variable can be represented by linear, quadratic, and third-degree trends (Winer, 1971). However, hierarchical modeling does not allow one to omit the quadratic and third-degree trends as in the example just given in the text. This is but one example of a nonhierarchical model of potential interest.

The difference in criterion variables has implications which go beyond out-of-range predictions. It is hardly profound, but nevertheless useful, to bear in mind that the GSK approach does allow one to model proportions directly. True, proportions are not inherently superior to logits or odds. Nevertheless, they are more widely understood than the latter, and some investigators will, no doubt, appreciate the possibility of explaining their regression coefficients as effects on probabilities, rates, or proportions. The regression coefficients produced by logit modeling cannot be interpreted in this manner, though the predicted logits can at least be transformed to proportions.[28, 29]

On the other hand, Theil (1970) and Cox (1970) argue, in effect, that logit modeling is better suited to handle the ceiling and floor effects found in modeling proportions, and that it is therefore inherently superior to modeling proportions.[30] This may well be true in many situations. However, it is easy to find examples in which modeling proportions is at least as effective as modeling logits. The NORC data analyzed in this article constitute a case in point.

A final difference worthy of mention here is this: logit modeling is in effect multiplicative in the natural scale (that is, when odds constitute the criterion variable, as in Equation 3); linear probability modeling is additive. If, perchance, one's theory stipulates that some variable exerts one or the other kind of effect, one normally ought to utilize the corresponding model. For example, the amount learned (or forgotten) during a given period of time is often theorized to be a product of the amount known in the first place, just as the amount of interest paid is a product of the principal. In this case, theoretical considerations indicate a logit model. More often than not, however, sociological theories are not so precise as to stipulate whether effects are additive or multiplicative, and the choice between techniques can seldom be made on this basis.

---

[27] As Jay Magidson has pointed out to me, if the GLS estimation procedure were modified to constrain estimates to the [0,1] interval, those estimates would become somewhat less "efficient" than otherwise. Incidentally, logit modeling suffers a logical difficulty of sorts too. If, for example, 27 people in some subgroup agree with a statement and none disagree, the odds of agreeing to disagreeing (27:0) are undefined. So is the logit. However, this usually presents no computational difficulty unless the model is saturated, in which case adding ½ to the frequency of every cell is recommended.

[28] $P = \Omega/(1+\Omega)$, where P is the proportion in a given category, and Ω is the odds of falling in that category. Also, although the coefficients of logit and linear probability models are not mathematically equivalent, they usually have much the same substantive implications. For example, consider the direct effect of region in 1963 (Table 4, col. 4). Controlling for education, the expected proportion favoring equal opportunity was .75 (regression constant minus regional effect). The expected odds, then, were 3.00 (.75/.25) in the South. Similarly, it may be shown that the expected odds outside the South were 5.67 (that is, .85/.15). Thus, the linear probability model implies that living outside the South increased the odds of favoring equal opportunity 1.88 times (5.67/3.00). This is near the estimate (1.93) from the multiplicative model (Table 5, col. 8).

[29] Those analyzing panel studies may well find the results from the GSK approach more appealing than those from other approaches. See Landis and Koch (1979).

[30] If what they say is true, it would seem that logit models will be more parsimonious than linear probability models when many of the observed proportions fall near either zero or unity.

In sum, it would be unwise to conclude that any of the above techniques is invariably superior to the others. The worth of a tool must be judged in terms of the task at hand. Thus, a technique must be selected only after asking questions of the following sort: Which technique allows me to ask the questions I need to ask, and which one is most useful in making sense of the data?

POLYTOMOUS DEPENDENT VARIABLES

To this point, only the analysis of dichotomous dependent variables has been explicated. The techniques outlined above can also be utilized to analyze polytomous dependent variables. As will soon become apparent, however, the techniques do not offer any fundamental conceptual breakthrough in the handling of polytomous dependent variables, and one can often do no better than analyze a series of dichotomies.

As a basis of illustration, imagine that NORC had allowed three, rather than two, categories of response to its question about equal job opportunity for blacks: "strongly agree" (SA), "agree somewhat" (AS), and "disagree" (DA). One could, of course, collapse categories so as to pit SA against the two lower alternatives or DA against the two upper alternatives. In this case, one logit would be predicted for each of the twelve subgroups of respondents (as in Table 1, col. 13). However, one may preserve the trichotomy by employing what Theil (1970) terms a "conditional logit model." (See also Goodman, 1970.) In this case, two logits would be predicted simultaneously for each subgroup: $\log(n_{SA}/n_{DA})$ and $\log(n_{AS}/n_{DA})$, where n_{SA}/n_{DA} is the odds of strongly agreeing rather than disagreeing and n_{AS}/n_{DA} is the odds of agreeing somewhat rather than disagreeing.[31] In general, when there are k categories in the dependent variable, $k-1$ logits for each subgroup are predicted by a conditional logit model.

Although there is nothing mathematically questionable about conditional logit modeling, the results are often difficult to interpret substantively. Consider, for example, the hypothetical data presented in Table 7 (cols. 7–9), in which attitudes towards equal opportunity are viewed as a function of respondents' schooling (col. 1). The odds which would be predicted by a saturated model (rendered multiplicative through the exponential transformation, as in Equation 3) are recorded in cols. 10 and 11. Notice that the figures in col. 11 seem to indicate that prejudice *increases* with education (n_{AS}/n_{DA} decreases as education increases). The odds in col. 10, on the other hand, suggest that prejudice *decreases* with education, as expected. The point is that, in *conditional* logit modeling, the proper interpretation of the odds involving any two categories (say, AS and DA) cannot be made without taking into account information about the other categories (SA, in this case). Making sense of all the coefficients simultaneously can be very challenging, especially when $k \geqq 4$. In this example, by the time one has integrated the information in cols. 10 and 11 so as to avoid a misimpression about the relationship between education and prejudice, one arrives at a result which is functionally equivalent to the one which would have been obtained if the trichotomy had been collapsed into a dichotomy in the first place—pitting SA against the two lower categories or DA against the two higher categories.

A related point is illustrated by the following example. Suppose that one wished to explain the odds that people *who completed high school* obtained at least some higher education instead of terminating their schooling, and suppose that one possessed trichotomous data on people who had finished their schooling: "did not complete high school" (NHS), "completed high school but no more" (HS), and "attended college or more" (C). Given this trichotomous dependent variable, one could utilize conditional logit modeling so as to predict two logits simultaneously: $\log(n_C/n_{HS})$ and $\log(n_{NHS}/n_{HS})$. The first of these would seem to be relevant to the question at hand. However, under conditional logit modeling, the model and the predictions for $\log(n_C/n_{HS})$ are *conditional* on the information about people who did not complete high school (NHS)—information which is irrelevant to the question at hand. It is important to understand that, if one simply disregarded NHS and developed an ordinary logit model for dichotomous dependent variables, one would probably obtain a different model and different predictions for $\log(n_C/n_{HS})$ than under conditional logit modeling. And given that the question does not concern people who failed to complete high school, the model and predictions from ordinary logit modeling would be patently superior to those obtained from conditional logit modeling. (See Fienberg, 1977; and Fienberg and Mason, 1978.)

---

[31] Mathematically equivalent results would be obtained if either SA or AS was treated as the anchor category instead of DA (which appears in both denominators).

The point is not that conditional logit modeling is worthless. Rather, the point is that it should be utilized only after one is certain that its conditional results are useful in answering the question posed by the research, and that, even if the results are conceptually appropriate, they will often be difficult to interpret. As will be documented later, published sociological applications of conditional logit modeling have often obscured these points.

When the categories of the dependent variable are ordered, another approach to analyzing polytomous variables is available: assigning numbers to the categories. For example, one might assign "1" to strongly agreeing that blacks should have equal opportunity; "0" to agreeing somewhat; and "−1" to disagreeing. A mean could then be calculated for each subgroup, and those means would become the criterion variable in an analysis based on the GSK procedure. (See Table 7, col. 15 and fn. e.) Under ordinary regression, assigning numbers to categories is objectionable for at least two reasons: (1) because the criterion variable would usually violate the assumptions of normality and homoscedasticity which underlie tests of significance, and (2) because calculating means on the basis of ordinal numbers entails a "leap of faith" which should be avoided if possible. Under the GSK procedure, the first objection is adequately

Table 7. Interpreting a Conditional Logit Model

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)	(14)	(15)
	Observed Frequencies:[a]				Geometric Mean[b]	Observed Proportions			Odds[c]		Coefficients[d]			Weighted Proportions[e]
Education	SA	AS	DA	Total		SA	AS	DA	n_{SA}/n_{DA}	n_{AS}/n_{DA}	SA	AS	DA	
Elementary	21	35	14	70	21.75	.30	.50	.20	1.50	2.50	−.035	.476	−.441	.10
Secondary	38	44	18	100	31.11	.38	.44	.18	2.11	2.44	.200	.347	−.547	.20
Higher	30	14	6	50	13.61	.60	.28	.12	5.00	2.33	.790	.028	−.819	.48

[a] Hypothetical frequencies.

[b] The cube root of the product of cols. 2, 3 and 4.

[c] Col. 10 equals col. 7 divided by col. 9; col. 11 equals col. 8 divided by col. 9.

[d] Col. 12 equals the log of the ratio of col. 2 to col. 6; col. 13 equals the log of the ratio of col. 3 to col. 6; col. 14 equals the log of the ratio of col. 4 to col. 6. Note that these coefficients may be easily transformed into the conditional odds in cols. 10 and 11. In row 1, $.476 - (-.441) = .917, e^{.917} = 2.50$ (col. 11)

[e] Col. 7 times 1 plus col. 8 times 0 plus col. 9 times −1.

handled; however, the second one remains a problem. Under certain circumstances, one may avoid the second objection by utilizing Thurstonian psychometric techniques (Torgerson, 1958). The "method of successive intervals" might allow one to assign the categories values on an interval scale (for example, 1.5, .2, −2.0). However, on many occasions one must simply weigh the objection to assigning numbers on a priori grounds against what may turn out to be a considerable advantage in making sense of the data. Some reputable statisticians such as Grizzle et al. (1969) have been willing to assign numbers to categories despite the leap of faith entailed.

For relatively new work in this vein which applies to logit modeling, see Duncan and McRae (1978) and Duncan (1979a).

PATH ANALYSIS

Since ordinary regression can sometimes be employed to obtain estimates for path diagrams, it is natural to ask whether the regression techniques outlined above may be employed for the path analysis of categoric variables. Goodman (1973a; 1973b; 1979b) has already devoted considerable effort to demonstrating how logit modeling can be used for this purpose. However, there appear to be several reasons why his approach will never be as useful as ordinary path analysis has been with continuous variables.

Consider a simple system in which X affects Y, and Y affects Z. In the path analysis of continuous variables, the symbol "Y" means the same thing in both structural equations; that is, the score on X affects *the score on Y*, and *the score on Y* in turn affects the score on Z. On the other hand, under the logit modeling proposed by Goodman for the analysis of categoric variables, the state of X affects *the logit of Y*, and *the state of Y* (not the logit of Y) affects the logit of Z. In other words, the criterion variable in the first equation does *not* become the independent variable in the second equation. As a consequence, a very nice feature of ordinary path analysis is lost. In ordinary path analysis, the observed correlation between, say, X and Z is easily decomposed into the component generated by the direct path from X to Z (zero in this example) and the component generated through the intervening variable Y. The observed correlation (r_{xz}) equals the product of the standardized path coefficients p_{yx} and p_{zy} in this example. In contrast, path analysis via logit modeling does *not* allow one to reconstitute the observed association between X and Z by examining the "path" coefficients. This is one of the reasons why it will probably never gain the currency that ordinary path analysis has enjoyed. For related observations, see Fienberg (1977:91), Gillespie (1977) and Brier (1978).

Another difficulty encountered in the path analysis of contingency tables is that the techniques outlined above usually detect important interaction effects. For example, in all the above analyses of the NORC data, the effect of region on attitudes towards equal opportunity was found to be contingent on time. Such interactions are awkward to depict in path diagrams. Notice that Goodman utilizes (rare) data without such interactions to illustrate his approach. Others have simply ignored the interaction effects in drawing their path diagrams (Gortmaker, 1979). Of course, one could adopt some convention to depict the interactions on a path diagram, but it is not yet clear that doing so would be worth the trouble.

Finally, there is an unsatisfying aspect to Goodman's approach to nonrecursive modeling—modeling in which feedback among variables is hypothesized. Suppose, for example, that W affected Y and that X affected Z. Furthermore, suppose that the two endogenous (dependent) variables Y and Z also affected one another. Path analysis would allow one to estimate (simultaneously) the effect of Z on Y (p_{yz}) and the effect of Y on Z (p_{zy}) (Duncan, 1975). Note that there is usually no theoretical justification for assuming that $p_{zy} = p_{yz}$ and that ordinary path analysis does not constrain the two to equal one another. Now suppose that the above four variables were dichotomous. Under the system developed by Goodman, the effect of Z on the logit of Y would be mathematically constrained to equal the effect of Y on the logit of Z (Goodman, 1977:32–3; 1973a; 1973b). It follows, then, that his technique should only be employed when this constraint is substantively reasonable. And because this is seldom the case, it would appear that his approach has only limited utility.

These shortcomings are not due to any lack of imagination on Goodman's part. He has explored the possibilities further than anyone else. Nevertheless, these shortcomings point to the fact that the path analysis of categoric variables does not yet offer some of the most important advantages currently offered by the path analysis of continuous variables.

EIGHT COMMON ERRORS

Most sociologists learn new statistical techniques by following examples rather than by reading original statistical treatises. Unfortunately, such a practice would likely mislead those who wish to master the "new" techniques for analyzing contingency tables: a high proportion of sociological articles based on these techniques contains statistical or methodological errors. Moreover, these errors are by no means confined to early sociolological applications. For example, Gortmaker (1979:286) claims that the criterion variable of his logit model is the log of the death *rate* instead of the log of the *odds* of dying rather than surviving; he misinterprets his coefficients accordingly. Kessler et al. (1979) make numerous errors, some of which will be described shortly, others of which are discussed in Gove and Swafford (1980). The following list of common mistakes will, perhaps, prove useful in efforts to avoid such pitfalls in situations where one variable is considered dependent on others. Because linear probability modeling has seldom found its way into sociological articles, the list focuses on log-linear and logit modeling.

(1) Failing to let theory guide the analysis. Recall that the equation for log-linear modeling (4) is peculiar: it has no substantive dependent variable. As a consequence, it is possible to churn out a log-linear analysis without even thinking about the causal relationships among variables. This is not to say that the technique is flawed. As was pointed out earlier, not only can one derive the coefficients of a logit model from Equation 4 (provided one stipulates the dependent variable), one can also test hypotheses about the conditional independence of variables. Davis (1974) takes the latter approach in his log-linear analysis of the NORC data; in doing so, he illustrates the theoretical morass which can be generated by failing to focus on a hypothesis. He arrives at the following model: (ER) (RJ) (RT) (EJT).[32] He (Davis, 1974:221) then offers the following interpretation of the first two terms:

> At last we are ready to state the substantive conclusions of this investigation. . . . First, there is a significant partial association between education and region, controlling for time and jobs, that is essentially similar in magnitude within each control condition. Second, there is a statistically significant partial association between region and jobs, controlling for time and education, that is essentially similar in magnitude within each control condition.

This interpretation is technically correct.[33] However, notice that the two conclusions are theoretically incompatible: the second conclusion is relevant only if education is either an antecedent or an intervening variable; the first one is relevant only if it is not. In addition, one would be hard put to come up with a theory which justified controlling on attitudes and education in interpreting the association between region and time. Davis recognizes shortcomings such as these, but he offers little advice on how to avoid them.

Goodman repeatedly advocates that logit modeling be employed when one variable is dependent on others (1970;

---

[32] Since Davis does not attempt to develop a logit model, he does not automatically include the (TER) term. Notice that his model does not reproduce the number of respondents in each subgroup. (Compare Table 1, col. 5 with the corresponding entries in cols. 18 and 19.)

[33] He might have described the (ER) term as follows: there is a (nonzero) conditional association between E and R which does not vary across combinations of J and T. However, a conditional association which does not vary across conditions is equivalent to the corresponding partial association.

1971; 1973a; 1973b).[34] In this example, viewing attitudes towards equal opportunity (J) as the dependent variable allows one to develop a logit model, and it therefore greatly simplifies the analysis: certain potential models become irrelevant and are therefore not tested, and coefficients have an interpretation far clearer than the one set forth by Davis (1974:224–7). This is not to suggest that log-linear modeling serves no useful function except as a vehicle for logit modeling. (For elaboration, see the concluding paragraphs of the above section on log-linear modeling.) However, opting for general log-linear modeling when logit modeling can be utilized normally complicates the analysis.

(2) Omitting interactions among independent variables when deriving a logit model from a log-linear model. Recall that (TER) was automatically included in all log-linear models tested in Table 3. In this manner, the observed associations among independent variables were taken for granted, as in ordinary regression. As was pointed out in the discussion of log-linear modeling, Goodman and most other statisticians advocate this procedure when logit models are derived from log-linear models. Nevertheless, several sociologists have failed to follow this procedure (Knoke, 1975; Knoke and Hout, 1976; Cohen and Kluegel, 1978; Kessler et al., 1979; also, see Gillespie's comment [1978] on Reynolds [1977b]). True, as was pointed out above, at least two competent statisticians have offered arguments for omitting statistically nonsignificant interactions among independent variables. However, these sociologists have not explicitly invoked those arguments.

One of the consequences of excluding interactions among independent variables is that one cannot calculate the unexplained variation in the *criterion* variable (as in Table 3, Model 1). At least two investigators have calculated this variation on the basis of irrelevant models (Knoke and Hout, 1976; Kessler et al., 1979).

(3) Failing to restrict modeling so as to reflect the study design. Again, consider the NORC data analyzed above. It is likely that the number of people sampled in each region during 1946 and 1963 was determined by the sampling procedure employed in gathering the data (see Davis, 1974:224). This implies that the TR association observed in the sample was fixed by the study design itself. As such, it reveals nothing about the TR association in the population. It would therefore be pointless to test the null hypothesis that T and R are independent in the population by omitting TR from some models. Instead, TR should be included in every model. *In general, no matter what hypotheses are in question, when observed frequencies are fixed by the study design, only those log-linear models which reflect the study design are legitimate* (Bishop et al., 1975:30). Incidentally, all the models described in Table 3 do fulfill this requirement by virtue of the inclusion of (TER).

Most authors are not explicit enough about their sampling procedures to allow one to determine whether or not they have followed this prescription. However, a clear violation appears in Kessler et al. (1979). The authors categorize the users of clinics (one state of variable D) into four quartiles on both variable B and C. Thus, BD and CD are both partly artifacts of the study design. Yet the authors test models which omit these associations. Also, notice that Davis (1974) does not constrain his models to reflect NORC's sampling design even though he (p. 224) acknowledges that it was not a simple random sample. Furthermore, he erroneously states that log-linear modeling assumes a simple random sample. The tests of significance for all the techniques outlined above are appropriate under stratified sampling as long as the tested models reproduce the frequencies which were fixed by the study design (Bishop et al., 1975).

(4) Categorizing continuous dependent variables. Knoke and Thomson (1977) categorize a dependent variable measured on an interval scale in order to render the data appropriate for logit modeling. Ordinary regression (perhaps with a transformed dependent variable to correct for skewness) should normally be utilized

---

[34] It would appear, then, that he would criticize authors such as Knoke (1974) and Burke and Turk (1975) who talk in terms of causal models but who do not derive logit models from their log-linear models.

in such a case: it allows one to test the same interactions as logit modeling permits, and the difficulty of interpreting coefficients from conditional logit models is avoided. Ordinary regression allows one to interpret coefficients as effects on the original scale of the dependent variable.

(5) Categorizing and collapsing independent variables. First, when one has a proper categoric dependent variable but continuous independent variables, one ought to consider discriminant analysis (readily available in SPSS). If one's independent variables include both continuous and categoric ones, there may be no fully satisfactory technique. If there happen to be enough cases at each level of the continuous variable, one may utilize the GSK procedure and assign numeric values to each level of the variable. Otherwise, one may be compelled to include categoric variables in a discriminant analysis or to categorize continuous variables for the sake of contingency table analysis. (See Bishop et al., 1975:357–61; see also Press and Wilson, 1978.)

Second, it is not necessary to collapse independent variables into dichotomies for the sake of interpretation. Many investigators consider the coefficients of general log-linear models particularly awkward to interpret substantively when they involve polytomous variables. As Guest (1974:501) puts it: "For our research, the Goodman system has one major operational drawback: the effect parameters are clearly interpretable only for dichotomous variables." Though it *is* difficult to interpret effects on polytomous *dependent* variables (as in conditional logit modeling), it is *not* at all difficult to interpret the effects of polytomous independent variables on dichotomous dependent variables. Consider the coefficients for the trichotomous variable "education" in the multiplicative model of the NORC data (Table 5, col. 7). They may be read as follows: in 1946, having a college (rather than a grade-school) education multiplied the odds of favoring equal opportunity by 2.97 (controlling on region); having a college rather than a high school education multiplied the odds by 2.09 (that is, 2.97/1.42). Numerous authors have unnecessarily collapsed the categories of their independent variables in the effort to make their data conform to misunderstood constraints of log-linear modeling.

Finally, bear in mind that Goodman (1979b:1086–7) inveighs against categorizing and collapsing variables:

> But none of Goodman's articles have suggested that the appropriate methods developed for the analysis of *qualitative* variables (e.g., methods developed for the analysis of conditional independence models, logit models, log-linear models, etc.) should be applied to arbitrarily dichotomized (or polytomized) *quantitative* variables. Indeed, the appropriate methods for the analysis of *qualitative* variables should not be applied in this inappropriate way.

One should not eschew categorizing continuous *independent* variables on the basis of this quotation, for other competent statisticians have expressed a more tolerant view of categorizing continuous variables (Bishop et al., 1975:343). However, one should be wary of arbitrary categorizations, as Goodman warns. The number of categories in a variable determines the number of degrees of freedom associated with it, and this, in turn, can affect the statistical significance of main effects and interactions in the model. In other words, trichotomizing a variable may give rise to a different model than dichotomizing it. (See Reynolds, 1977b; Gillespie, 1978; and Goodman, 1979b.)

(6) Relying too much on variance explained in evaluating the importance of variables. Even if *identical* unstandardized regression equations explained a certain dependent variable in two populations, the "relative importance" of two predictor variables might vary drastically across the two populations as a result of differences in the variances of those predictors. This, in itself, should make investigators cautious about judging importance on the basis of unique variance explained (that is, variance explained by a variable when it is last to enter the equation). However, an added caution is warranted in the case of contingency table analysis. More often than not, interactions are detected by such an analysis, and the importance of those interactions may easily be misjudged on the basis of the unique

variance they explain. Spenner (1975:515) terms a certain interaction as "relatively small" because it explains only 13% of the total error chi-square. But consider the NORC data above. The direct effect of region on the odds of favoring equal job opportunity was found to drop from 3.13 to 1.95 between 1946 and 1963. Intuitively, the difference between these coefficients represents a fair-sized interaction. Yet it explains less than *two* percent of the variation. (Subtract the error chi-square for Model 10 from the one for Model 7, then divide the difference by the error chi-square for Model 1.) See also fn. 11 for further comments on the interpretation of variance explained.

(7) Failing to collapse tables when necessary. Consider the simple system W affects X, X affects Y, and Y affects Z. It is well known that the path coefficient representing the effect on W on X may be obtained by simply regressing X on W, provided that the disturbance term is uncorrelated with W. According to Goodman, a proper path analysis of categoric variables also requires that Y and Z be ignored at this stage. In other words, one must collapse the four-way table (WXYZ) into the two-way table (WX) to properly estimate the effect of W on the logit of X. If one instead uses the four-way table, one obtains the *partial* effect of W on the logit of X controlling on Y and Z. Of course, it would be nonsensical to control for the consequent variables. Errors of this sort occur in Kessler et. al. (1979) and Knoke (1974:60). See also Reynolds (1977b), Goodman (1979b), and Gillespie (1978).

(8) Failing to interpret the magnitude of coefficients. It is no doubt commonplace to point out that effects can be statistically significant, yet substantively unimportant because of small magnitude. Obviously, understanding the magnitude of coefficients is important. More often than not, however, log-linear analyses in sociological publications dwell on tests of significance and falter in explicating the meaning of coefficients. This fact is more than a little ironic, for, supposedly, one of the primary virtues of parametric techniques is that they produce coefficients of estimable precision. What is the point of such precision if one can only vaguely state the meaning of coefficients? There is nothing mysterious about these techniques in cases where one variable is considered dependent on others, and confusion about the connection between coefficients and ideas is usually the fault of the author, not of the reader.

The most grievous examples of this problem occur in articles relying on conditional logit modeling (Knoke and Hout, 1976; Knoke and Thomson, 1977; Burke and Turk, 1975; Hogan, 1978). If coefficients are given at all, they are invariably presented as in Table 7, cols. 12–14. The precise interpretation of such coefficients is horrendous. Consider, for example, the "−.441" and "−.547" in col. 14. These may be interpreted as follows: the log of the ratio of the number of people who disagreed to the geometric mean of the people in all three response categories drops from −.441 among those with elementary school educations to −.547 among those with secondary school educations. (See Table 7, fn. d.) Such abstruse quantities should be utilized only by those who are willing to explain the substantive significance of the magnitudes fairly precisely.

Some good sociological applications of logit modeling may be found in Hagan (1977) and Fienberg and Mason (1978). This is by no means a complete list of good examples.

A FINAL OBSERVATION

Reviewing the gradual adoption of the "new" forms of contingency table analysis, one cannot help but be struck anew by the extent to which the available statistical techniques condition the hypotheses raised by investigators. For example, whether variables are continuous or categoric, it is entirely plausible that the effect of one independent variable is contingent on the level of another—that there is interaction or specification. This possibility is routinely ignored in the ordinary regression of continuous variables, where it is inconvenient to examine, yet it serves as a major substantive focus in many contingency table analyses, where the new techniques have made such questions easy to raise. This is not to say that the new techniques have markedly raised the maturity of sociological analysis: one can easily find numerous cases in which investigators have done violence to their theories or their data in the name of the new techniques. The point is that one must ever be watchful that all statistical techniques are kept in the service of ideas, and that whenever the new techniques are not employed in such a fashion as to render the connection between ideas and data clear, they have been ill-used.

APPENDIX

The purpose of this appendix is to explicate the relationship between log-linear and logit modeling by demonstrating how Equation 5 is derived from Equation 4. In this example, the aim is to derive a logit equation which predicts log (F_1/F_2), where F_1 is the number of respondents in a given subgroup who *agreed* that blacks should have equal opportunity, and F_2 is the number who disagreed in that same subgroup. Now, $\ln(F_1/F_2)=\ln(F_1)-\ln(F_2)$. This implies that the logit can be estimated by first estimating $\ln(F_1)$, then subtracting $\ln(F_2)$. These latter two quantities can be estimated with log-linear equations such as Equation 4. Specifically:

$$\begin{aligned}\ln(F_1) = {} & \lambda^*_{13} + \lambda^*_1 J_1 + \lambda^*_{14}T + \lambda^*_{15}E_h + \lambda^*_{16}E_c \\ & + \lambda^*_{17}R + \lambda^*_2 J_1 T + \lambda^*_3 J_1 E_h + \lambda^*_4 J_1 E_c \\ & + \lambda^*_5 J_1 R + \lambda^*_{18}TE_h + \lambda^*_{19}TE_c + \lambda^*_{20}TR \\ & + \lambda^*_{21}E_h R + \lambda^*_{22}E_c R + \lambda^*_6 J_1 TE_h \\ & + \lambda^*_7 J_1 TE_c + \lambda^*_8 J_1 TR + \lambda^*_9 J_1 E_h R \\ & + \lambda^*_{10}J_1 E_c R + \lambda^*_{23}TE_h R + \lambda^*_{24}TE_c R \\ & + \lambda^*_{11}J_1 TE_h R + \lambda^*_{12}J_1 TE_c R \,, \qquad (6)\end{aligned}$$

$$\begin{aligned}\ln(F_2) = {} & \lambda^*_{13} + \lambda^*_1 J_2 + \lambda^*_{14}T + \lambda^*_{15}E_h + \lambda^*_{16}E_c \\ & + \lambda^*_{17}R + \lambda^*_2 J_2 T + \lambda^*_3 J_2 E_h + \lambda^*_4 J_2 E_c \\ & + \lambda^*_5 J_2 R + \lambda^*_{18}TE_h + \lambda^*_{19}TE_c + \lambda^*_{20}TR \\ & + \lambda^*_{21}E_h R + \lambda^*_{22}E_c R + \lambda^*_6 J_2 TE_h \\ & + \lambda^*_7 J_2 TE_c + \lambda^*_8 J_2 TR + \lambda^*_9 J_2 E_h R \\ & + \lambda^*_{10}J_2 E_c R + \lambda^*_{23}TE_h R + \lambda^*_{24}TE_c R \\ & + \lambda^*_{11}J_2 TE_h R + \lambda^*_{12}J_2 TE_c R \,. \qquad (7)\end{aligned}$$

Since both equations pertain to the same subgroup, terms not involving J are the same in both equations. Thus, when Equation 7 is subtracted from Equation 6, the terms with subscripts 13 through 24 drop out. Thus,

$$\begin{aligned}& \ln(F_1)-\ln(F_2)=\ln(F_1/F_2) = \\ & \quad (\lambda^*_1 J_1-\lambda^*_1 J_2) + (\lambda^*_2 J_1 T-\lambda^*_2 J_2 T) \\ & \quad + (\lambda^*_3 J_1 E_h-\lambda^*_3 J_2 E_h) \\ & \quad + \ldots + (\lambda^*_{12}J_1 TE_c R-\lambda^*_{12}J_2 TE_c R) \,. \qquad (8)\end{aligned}$$

Equation 8 may be simplified to Equation 5 in the text. Recall that the coefficients for each variable *sum* to zero under effect coding. For example, in Table 4, col. 1, the coefficient for South is −.09; the coefficient for Other is .09. In other words, the absolute values of the two coefficients are equal to one another; only the signs differ. Thus, when the second coefficient is *subtracted* from the first, the difference always equals twice the value of the first; that is, −.09−(.09)=−.18. Likewise, each of the parenthetical terms in Equation 8 equals twice the first of the two terms within the parentheses. For example,

$$(\lambda^*_1 J^*_1-\lambda^*_1 J_2) = 2^{1*}J_1$$

and $(\lambda^{½}_{12}J_1 TE_c R-\lambda^*_{12}J_2 TE_c R) = 2\lambda^*_{12}J_1 TE_c R.$

These terms appear in Equation 5, except that the subscript to J is not written out. This completes the derivation of a logit equation (5) from a log-linear equation (4).

Notice that deriving an equation for the logit from a log-linear equation does not depend on including the (TER) term in the log-linear equation. In other words, if, say, $\lambda^*_{24}TE_c R$ or $\lambda^*_{16}E_c$ were omitted from Equations 4, 6, and 7, Equations 8 and 5 would not change. This is because terms which do not involve J drop out when Equation 7 is subtracted from Equation 6. However, although these terms drop out, they *do* affect the estimates of F_1 and F_2 given by Equations 6 and 7, respectively, and they therefore affect the estimate of $\ln(F_1/F_2)$. As is explained in the text, statisticians agree that a logit model may be legitimately derived from a log-linear equation in which (TER) is included. A few, however, argue that leaving out nonsignificant terms from (TER) is also all right, as long as those terms are not affected by the study design.

RESEARCH NOTE

SEX AND INVOLVEMENT IN DEVIANCE/CRIME: A QUANTITATIVE REVIEW OF THE EMPIRICAL LITERATURE

DOUGLAS A. SMITH AND CHRISTY A. VISHER
Indiana University

American Sociological Review 1980, Vol. 45 (August):691–701

Forty-four studies reporting data on the relationship between sex and indicators of deviance/criminality are reduced to a single data base. Contingency tables (1,118) are generated from the extant empirical literature on sex and deviance and comparable statistics are calculated, using instances where the sex-deviance relationship was reported for specific categories of class position, age, data type, year of study, level of family intactness, race, place of residence, and type of offense. The findings from 1,118 instances are summarized, and patterns are discussed. The overall results indicate that the magnitude of the relationship between sex and deviance is contingent on the year the data were gathered, the type of data used, the percentage classified as deviant in a particular table, whether the indicator of deviance is a single behavior or composite index, race, and the specific offense. Moreover, analysis demonstrates that trends in the sex-deviance relationship over time vary by type of data and by population group.

Interest in differences between males and females in deviance/criminality has generated several recent empirical investigations and spawned a plethora of theoretical debates. While this attention has touched on a variety of topics, one central issue is how differences between the sexes in deviant/criminal behavior vary over time. Some say women are becoming more aggressive and catching up to males in the volume of crimes they commit (Adler, 1975; 1977; Oakley, 1972; Noblit and Burcart, 1976; Vedder and Somerville, 1970; Ward et al., 1969) while others maintain that the new female criminal is more of a social myth than an empirical reality (Crites, 1976; Heidensohn, 1968; Steffensmeier, 1978). Unfortunately, little data have been brought to bear to assess the changing involvement of women in crime, and that which has been reported is mostly analysis of official indicators of criminality such as arrest rates (cf. Klein and Kress, 1976; Noblit and Burcart, 1976; Simon, 1975; Simon and Sharma, 1979; Steffensmeier, 1978; Ward et al., 1969). Although examination of arrest or conviction trends can be enlightening, these types of data alone cannot adequately answer many of the most relevant questions. In particular, changes in official statistics may indicate more about how social control agencies respond to males and females than about changes in the amount of deviance/crime committed by men and women (Chesney-Lind, 1973; Deming, 1977; Haskell and Yablonsky, 1974; Klein and Kress, 1976; Nagel and Weitzman, 1972; Noblit and Burcart, 1976; Simon, 1975). To correct for that bias, some contemporary observers have tried to summarize trends reflected in self-report studies to ascertain changes in the criminality of women relative to men (e.g., Cernkovich and Giordana, 1979; Datesman et al., 1975; Jensen and Eve, 1976). But often overlooked in

We are indebted to several people who have assisted us in many respects. Professor Charles Tittle has been a constant source of invaluable comments on several drafts of this paper. Professors Neal Shover and Martin Gold generously made data available to us from the Tennessee Youth Survey and the 1967 and 1972 National Survey of Youth. Finally, Professors Larry Griffin, Barbara Reskin, and Peter Burke provided many insightful suggestions along the way. Of course, the present authors are solely responsible for the ideas presented or any errors that may appear in the text.

analysis of the self-report studies is that any survey is specific to the spatial-temporal setting in which it occurs (Przeworski and Teune, 1970), and, to date, no meaningful attempt to make sense out of the overall body of empirical evidence about male-female differences in criminality/deviance has been reported. Our knowledge about temporal changes in the relative rule-breaking propensity of males and females remains problematic.

To illustrate, Adler (1975) argues that women are increasing their involvement in all types of offenses and paints a picture of a rising new breed of violent, aggressive female offenders. But some scholars emphasize that women's involvement in crime may be contingent on the type of offense considered. While one group suggests there is a convergence between the sexes for violent crime (e.g., Noblit and Burcart, 1976), others point out that the amount of violent crime committed by adult women may be decreasing (Klein and Kress, 1976; Simon, 1976:661) or remaining stable (Crites, 1976; Heidensohn, 1968; Norland and Shover, 1977; Simon, 1975; Simon and Sharma, 1979; Steffensmeier, 1978). In addition, some argue that the gap between the sexes is narrowing only for property offenses such as larceny, embezzlement, and fraud (Crites, 1976; Klein and Kress, 1976; Noblit and Burcart, 1976; Simon, 1975; Steffensmeier, 1978), while others maintain that convergence is limited to personal offenses such as drug and alcohol use (e.g., Gold and Reimer, 1974). Moreover, several scholars have argued that variations in the sex-deviance relationship over time may depend upon demographic characteristics of potential offenders. Many suggest that the gender gap may be inversely correlated with the age of the offender (Adler, 1975; d'Orban, 1972; Mannheim, 1965; Noblit and Burcart, 1976; Radzinowicz, 1937; Pollack, 1950). Further, the relationship between sex and deviance could be contingent on urban/rural differences. Specifically, differences between males and females in deviance/crime involvement presumably may be converging more in urban than in rural areas because the social positions of males and females are more equal in urban than in rural areas (Newberg, 1967; Radzinowicz, 1937). Finally, race has been cited as a possible factor in the convergence controversy, with some scholars arguing that male-female differences are smaller for whites (Deming, 1977) and others suggesting that the gap between the sexes is smaller for blacks (Wolfgang, 1958). Thus, no consensus exists concerning the magnitude of or change in the sex-deviance relationship or even the variables that are important specifiers of a gender/deviance relationship.

The purpose of this paper is to provide some insights into the existing chaos. First, we reduce the extant research literature on sex and deviance (both self-report and official sources) to a single data base. Without such homogenization, meaningful conclusions are impossible because the various studies which report data on sex differences and deviance use different research methodologies, types of data, forms of reporting, and samples. Therefore, merely counting the proportion of studies that report certain relationships between sex and deviance would be likely to produce erroneous conclusions because the studies are simply not comparable in their original forms. The present approach allows us to treat the magnitude of association between sex and deviance, derived from each study, as a dependent variable to be explained by characteristics of the study. In addition, this method generates a meaningful and succinct summary of the available evidence.

METHODS

Our research design is patterned after the approach used by Tittle et al. (1978) in their analysis of the aggregate literature on social class and criminality. We attempted to locate every instance in the literature which reported a relationship between gender and various deviance/crime indicators including self-reports of actual deviances and official recordings of arrest, police contact, conviction, or incarceration. Each report of that relationship for a specific category of class position, age, offense type, race, level of family intactness, and level of urbanization was treated as a separate "instance." Thus, one published study could generate several "instances." The data reported in each study were rearranged into ordinal contingency tables and a gamma measure of association was calculated for each table.[1] This procedure allowed us to reduce the available evidence to 1,118 separate measures of association that serve as independent indicators of the magnitude and direction of the sex-deviance relationship.[2] While this data base represents the extant empirical literature on sex and involvement in deviance, it is unclear whether the pooled literature is representative of the general population for the time period covered (1940–1975). Thus, generalizations beyond the population of studies should be interpreted with some element of reserve.

To explain variation in the magnitude and direction of the sex-deviance relationship across studies, we considered methodological characteristics of the work, and demographic characteristics of the respondents, as they applied to each "instance" (contingency table). For each "instance," the following specific independent variables were indexed: (1) sample size; (2) the type of sample (complete, random, or convenience); (3) percentage classified as deviant; (4) year data were gathered (3 years prior to publication date, if not reported by author); (5) number of categories in the deviance indicator; (6) the type of deviance indicator (incidence, frequency, or seriousness); (7) sophistication of the measure of deviance (single behavior vs. some composite index); (8) the specific kind of deviance; (9) the class position, race, age, and level of family intactness of the respondents; (10) the type of place (rural, urban, or mixed) from which the sample was drawn; and (11) whether the data were self-reported or official indicators of crime/deviance.

FINDINGS

Our first goal is to determine the amount of variance in the relationship between sex and deviance that can be accounted for by subject characteristics, methodological aspects of the studies and the type of offense. Table 1 reports the results of such a test. Subject characteristics (column 1) are dummy coded, with an overall suppressed category containing all cases where no differentiation was made by class position, family background, race, age, or the level of urbanization of the area from which the sample was drawn. As a pool, subject characteristics account for 12.1% of the variance in the sex-deviance relationship. But this does not tell us how the relationship

---

[1] The contingency tables were ordered in such a way that positive values of gamma indicate a larger proportion of males were classified as deviant vis-à-vis females, and negative gammas imply a predominance of females were classified deviant vis-à-vis males. Gamma was selected as the measure of association because marginal distributions do not affect the magnitude of gamma and do not change its meaning as a Proportional Reduction of Error (PRE) measure of association (see Mueller et al., 1977:215–7).

[2] The specific 44 studies are: Akers, 1964; Austin, 1978; Ball et al., 1964; Berger and Simon, 1974; Brown, 1972; Burkett and Jensen, 1975; Cernkovich and Giordana, 1979; Dentler and Monroe, 1961; Forslund, 1970; Gold, 1966; 1970; Gold and Reimer, 1974; Green, 1970; Hathaway et al., 1960; Havighurst et al., 1962; Heise, 1968; Higgins et al., 1977; Hindelang, 1971; 1973; 1974; Hirschi and Stark, 1969; Jensen and Eve, 1976; Kratcoski and Kratcoski, 1975; Lowe, 1966; Moses, 1947; Nye, 1958; Palmore and Hammond, 1964; Porterfield, 1946; Rhodes and Reiss, 1970; Short and Nye, 1958; Norland and Shover, 1977, Tennessee Youth Survey Data; Slocum and Stone, 1963; Steffensmeier, 1978; Steffensmeier et al., 1979; Stewart, n.d.; Stinchcombe, 1964; Tittle and Villemez, 1977; Voss, 1963; 1964; Voss and Hepburn, 1968; Walberg et al., 1975; Wallerstein and Wyle, 1947; Weis, 1976; Williams and Gold, 1972. All tables were generated from the published reports except for Steffensmeier (1978), where we consulted the *Uniform Crime Reports* and the *Current Population Reports* (U.S. Bureau of the Census, 1974; 1975) to reconstruct Steffensmeier's procedure.

Of course, not all studies of sex differences in deviance reported data complete enough to permit derivation of contingency tables. For example, studies using matched pairs of offenders (Bertrand, 1969; Morris, 1965; Reige, 1972) or only institutionalized populations (e.g., Barker and Adams, 1962; Cowie et al., 1968; Cockburn and Maclay, 1965; Gibbons and Grizwold, 1957; Mott, 1973; Robin, 1963; Suval and Brisson, 1974) were not usable because the number of persons classified as deviant and nondeviant were fixed by the researchers. Thus, these data are not representative of the amount of deviant involvement, by sex, in a given population. In addition, some studies did not report data complete enough to identify the number of nonoffenders by sex (d'Orban, 1972; Radzinowicz, 1937; Simon, 1975); failed to report the total sample size (Wise, 1968); or used an a priori classification of subjects into deviance categories (Datesman et al., 1975).

between sex and deviance varies across subject characteristics. To solve this problem, we examined each variable separately. For example, to determine whether the relationship between sex and deviance is similar across categories of class position, we selected only those instances which reported data on the status position of respondents (N=260). We then estimated an equation suppressing one of the class variables (low SES) and including high SES and the other subject characteristics. If the sex-deviance relationship does not vary by class position, the metric coefficient for high SES in our reestimated equation should not be significantly different from zero. And, in fact, it is not (t=−.487). Thus, the relationship between sex and deviance does not differ across categories of class position. In examining all other subject characteristics, we discovered two significant differences. The association between sex and deviance proved to be smaller among nonwhite samples than white samples (t=2.284, N=316). And, second, samples of adults yielded stronger associations between sex and deviance than did samples of youth (t=7.587, N=1,118). No significant differences were found between rural and urban samples (t=1.790, N=442) or between those from intact and not-intact family backgrounds (t=−.951, N=146).

Methodological characteristics—type of sample, number of categories of deviance, percentage classified as deviant, year the data were collected, scale (a measure of the complexity of the indicator of deviance), type of data (self-report or official), and sample size—collectively explain 30.4% of the variance in the magnitude of association between sex and deviance. The type of sample and the number of categories on the deviance item have no significant effect on the sex-deviance relationship. But five variables do affect this relationship.

Specifically, the percentage classified as deviant in a particular instance exerts a negative effect on the magnitude of the sex-deviance association. As the percentage classified as deviant in a particular instance increases, the gap between male and female involvement in deviance decreases. This is probably because the percentage classified as deviant in a given instance indicates the seriousness of the offense being considered—visual inspection suggests that the greater the number of offenders, the less serious the offense. Hence, the results provide empirical support for the argument that the extent to which male deviance exceeds female deviance varies directly with the seriousness of the offense. The metric coefficient for type of data (.221) shows that there is greater disparity in the amount of deviance committed by males and females when official statistics are used. But, since data type is a dichotomous variable, we can be more specific. Given two studies of equal sample size, identical types of samples, the same number of categories of deviance, equal percentages classified as deviant, and both drawn in the same year, the gamma from the study using official data will be, on the average, .221 higher than the gamma using self-reports. The variable scale indicates whether the measure of deviance used in a particular instance is based on a single behavior or on two or more behaviors combined in some type of index. The results suggest that the gap between males and females is smaller when the indicator of deviance consists of more than one behavior. Possibly multiitem indexes of deviance are more likely to contain offenses that are less serious, and if females are more likely to commit less serious offenses, the differences in the sophistication of the measure will reflect this.

But the most important of the methodological variables is the year the data were gathered. Much theoretical debate has centered on the question of whether males and females are becoming more similar in deviance as the struggle for female equality has progressed. Hence, it is especially noteworthy that the data do show that the gap between males and females in the amount of deviance committed has been narrowing over time. But it is possible that this convergence may be more salient for certain demographic groups—a question to which we will turn later in the analysis.

The set of variables indicating type of offense account for 26.7% of the variance in the relationship between sex and deviance. These variables are dummy coded, and the analysis hinges on a suppressed category containing cases where the type of deviance was not specified (e.g., police contact, arrest) or where an index score was used which involved two or more types of acts. Gamma was regressed on the four offense categories, type of data used, and the year the data were collected, systematically rotating the suppressed category to determine if the sex-deviance relationship varies by type of offense, net of year and data type. This procedure showed that the gap between males and females is least for personal offenses (e.g., drug and alcohol violations). The gender discrepancy is intermediate for youth offenses (e.g., truancy, school problems) and property offenses (e.g., theft, embezzlement, fraud). Finally, males and females are found to differ most in involvement with violent offenses.

While the preceding analysis offers evidence of the effects of specific variables within three general categories (subject characteristics, methodological characteristics, and offense type), it is desirable to determine the net effect of each variable. When we regressed gamma on all 20 variables simultaneously, these variables explained 47.7% of the variance in the gammas; but, because many of these 20 variables add very little, we reestimated the equation by successively deleting those variables which made no significant contributions to the total variance in the sex-deviance relationship. The results are reported in Table 2.

Table 2 indicates that the year the data

were gathered has a strong negative effect on the magnitude of gamma. But in order to answer the relevant theoretical questions, it is desirable to assess the effect of year the data were gathered by type of offense, subject characteristics, and types of data (self-report or official). Technically, we will compare the slopes for year *across* offense categories, subject characteristics, and type of data. Data for these comparisons are presented in Table 3.

The coefficients in the first column of Table 3 suggest a significant decline over time in the magnitude of the sex-deviance relationship for all offense types.[3] Additionally, the statistical tests for equality of the slopes indicate that the convergence between gender and deviance is significantly greater for personal and youth offenses than for property and violent offenses.[4] Moreover, the rate of convergence is similar across SES groups (t=1.075), for intact versus not-intact family situations (t=1.009), and in rural and urban places (t=.676).

However, the sex-deviance relationship has not declined at the same rate for whites and nonwhites. The data suggest that the gap between white males and females in amount of deviance/crime engaged in has remained stable over time (beta = −.006), while a significant convergence has occurred among nonwhite populations (beta = −.285), and the statistical tests indicate that the slopes were probably drawn from different populations (t=3.898). Similarly, the rate of convergence differs significantly across age categories. Although the gender-deviance relationship has narrowed for both youth and adults, the decline has been more rapid among youth than among adults (t=3.880). Finally, the analysis documents that both self-report and official data studies portray a narrowing gap between males and females in involvement in deviance. However, the self-report data indicate that the gender disparity is declining more rapidly than was

---

[3] To obtain the set of variables used as controls, we first regressed gamma on all 20 independent variables for the subsamples of violent, property, personal, and youth offenses. We then reestimated each of the four equations with only those variables which were significant when all were included in the original equation. Year was included even if it was not significant. Then, any variable which was significant in *any* of the four equations was selected to be included in the final pool of control variables. We did this so that each estimate of the effect of year for violent, personal, youth, and property offenses would be net of a common set of control variables. The specific variables used as controls for the estimates by offense types were (1) data type; (2) sample size; (3) percentage classified as deviant; (4) nonwhite; (5) urban; (6) age of respondents; (7) high SES and (8) scale. Thus, we estimated one equation with year, and with these eight controls, four times (once for each offense category); and the coefficients in Table 3 are the coefficients, for year, from this equation. The same logic was followed for data type and population comparisons.

[4] Statistical significance of metric coefficients across equations was measured by:

$$t = \frac{b_1 - b_2}{[V_1(SEb_1^2) + V_2(SEb_2^2)/(V_1 + V_2)]^{1/2}},$$

where b_1 = metric coefficient for population 1
V_1 = N − K − 1 for population 1 with N = sample size, K = number of regressors;
V_2 = N − K − 1 for population 2;
SEb_1 = standard error of metric coefficient for population 1.

The specific t-ratios for the slopes of year by offense categories are:

	PERSONAL	YOUTH	PROPERTY
VIOLENT	1.929	2.320	.656
PERSONAL		.293	2.735
YOUTH			3.149

evidenced by official data sources (t=8.868).

SUMMARY AND DISCUSSION

Accumulated data suggest that the magnitude of the relationship between sex and deviance/criminality is smaller for: (1) self-report vs. official data sources; (2) personal and youth offenses vs. violent and property offenses and undifferentiated official records; (3) composite indicators of deviance vs. single behavior measures; and (4) nonwhite vs. white populations. Further, the sex-deviance relationship is larger for both adults vs. youth and urban vs. rural samples. Moreover, as the percentage classified as deviant in a particular instance increases, the magnitude of the sex-deviance relationship decreases. Finally, over time, the association between sex and deviance has been decreasing.

But the converging trend over time in the sex-deviance relationship can be more precisely specified. The data indicate a narrowing of the gap between males and females in instances of youth, personal, property, and violent offenses. But the rates of convergence vary across offense categories, suggesting that the leveling of deviant/criminal conduct by sex is specific to the type of offense. Indeed, it appears that women *are* closing the gap in terms of involvement in minor deviant acts but that equal gender representation in the area of serious criminal behavior has not yet occurred. And the trend toward equality in this arena is moving at a slower pace vis-à-vis involvement in less serious deviant acts. In addition, while the gender-deviance relationship is declining for both youths and adults, the data suggest that this trend is stronger for youths. This seems consistent with the view that women may be experiencing greater structural opportunities to commit deviant acts due to a leveling-out of the social roles of men and women. It is at least plausible that shifting sex-role ideologies may be more salient for younger females and, thus, may have a greater impact upon the behavior of this group. Indeed, the fact that the convergence noted in the sex-deviance relationship is stronger for youths is consistent with this hypothesis.

One of the most interesting findings is the interaction with race. The data show a significant convergence in male and female involvement in deviance/criminality for nonwhites but no discernible pattern for whites. Thus, the deviant conduct of black females is becoming more similar to that of black males. This finding is consistent with much stratification research which indicates a greater similarity of the economic and social roles of black females vis-à-vis black males, compared to white females vis-à-vis white males (e.g., Freeman, 1973; Treiman and Terrell, 1975). This finding also seems to support the argument that greater social equality of women is associated with a decrease in the relative disparity of deviant conduct, by sex. This interpretation follows from the fact that black women have experienced more rapid advances in educational and occupational attainment relative to black men, than have white women experienced relative to white men. Thus, as the social and economic roles of black men and women have been converging, their relative propensity toward deviant/criminal conduct has also narrowed.

One other interesting finding of the present research is the significant contrast between self-report and official data samples. While the relative involvement of males and females in deviance/crime is trending toward similarity for both self-report and official measures, the rate of decline is significantly greater for self-reported deviance. This difference may reflect the less serious item content of most self-report data (e.g., Hindelang et al., 1979). But while this argument seems plausible for explaining *static* differences in the magnitude of the sex-deviance relationship, the extension of this argument for explaining the different time trends seems less clear. For example, if the slopes of year for self-report and official data were parallel, then the difference between the *indicators* of male and female involvement in deviance would be a constant, over time. But the data reported in Table 3 reject the hypothesis of parallel slopes. Specifically, if the magnitude of the sex-deviance relationship evidenced by official data is some value (X) for a given year, and the gamma for the self-report data for the same year is (X-D) (where D is a measure of difference), then the present data suggest that, over time, D has been increasing. Thus, the difference between official and self-report measures of the sex-deviance relationship is expanding over time. While variable item content may help to explain the structural difference of these two slopes at a given point in time, other factors may be relevant in accounting for the different trends. One possibility may be that self-report and official indicators of deviance are not measuring the same latent variable (see Bridges, 1978). Thus, some interesting interpretations emerge. It may be that official data taps a dimension of serious criminal involvement while the self-report data deals with only a truncated distribution of deviant acts (those on the less serious end of the continuum). If this is the case, then the extant empirical literature suggests that, over time, men and women are becoming more similar in involvement in marginal (i.e., less serious) deviant acts, but that, for the more serious deviant acts, the convergence between men's and women's involvement is less rapid. Alternatively, the self-report measures may be more sensitive to actual changes in the deviant/criminal behavior of men and women than is the official data which may be an index of the response of social control agencies to that behavior. Given this interpretation, the present data would suggest that the gap between males and females in involvement in deviance/crime is narrowing, but that official reactions to this change are occurring at a significantly slower rate.

COMMENTS

ON "STRATIFICATION IN A DUAL ECONOMY"*

(COMMENT ON BECK ET AL., *ASR*, OCTOBER, 1978)

Beck et al. (1978) contrast what they term "individualistic" and "structural" theories of the distribution of earnings in an analysis of data from the 1975 and 1976 General Social Surveys (GSS) of the National Opinion Research Center (NORC) (1977). The purposes and results of their study are aptly summarized in their conclusion (Beck et al., 1978: 717):

> Our analysis examines the existence and the importance of industrial sectors, as hypothesized by the dual economy literature, on the process of earnings determination. Since the status attainment and neoclassical income models rest on the assumption of labor market homogeneity, our efforts to test a theoretically-derived model of nonhomogeneity are of direct relevance for those research traditions. Using a distinction between core and periphery industrial sectors derived from Bluestone et al. (1973), we address our analysis to three basic questions: (1) Are there significant differences in the economic status and composition of the core and periphery labor forces? (2) Can sectoral differences in economic status be reduced to differences in the quality of their respective labor forces? And, (3) to what degree are the economic returns to sex, race, human capital, and occupation-labor force variables the same in both sectors?
>
> The analysis provides clear answers to all three questions. The core and periphery sectors *do* exhibit significant differences in both earnings levels and in labor force composition. The sectoral differentials in earnings *cannot* be explained away by differences in labor force quality. The relationships between earnings and human capital as well as occupation-labor force variables *do* differ significantly between core and periphery sectors. Whether considering the biologically-fixed attributes of race and sex, the human capital variables, or the occupation-labor force variables, we find that the real dollar returns on these worker characteristics are greater in core industries than in periphery industries.
>
> The importance of these findings for the neoclassical research tradition in stratification should be clear. In face of strong empirical evidence contrary to the implicit tenet of labor market homogeneity, parameter estimates which are conditional on this assumption can no longer be treated as appropriate bases for the construction of sociological theory or social policy. Such simplistic models lead to a serious misspecification and misrepresentation of the social processes underlying individual earnings determination. In contrast, the notion of economic sectors appears to hold substantial promise as a theoretical concept and as an exemplar for a research program aimed at identifying structural aspects of the socioeconomic order.

There is no reason to question the first two of Beck et al.'s (1978) three major findings: industrial differentials in labor force composition and remuneration are well known. Their analysis and its conclusions focus primarily upon the third finding, "the relationships between earnings and human capital as well as occupation-labor force variables *do* differ significantly between core and periphery sectors." For example, Beck et al. (p. 706) state, "the present analysis will focus on the issue of fixed returns—the assumption that economic returns to worker characteristics are uniform." On this point their analysis is wrong. Beck et al. incorrectly classify a small number of GSS respondents as zero earners. These few observations dominate their regression analyses. As a result, Beck et al. "detect" several nonexistent interaction effects; they also fail to detect one important interaction effect. Their regression analyses are wrong in virtually every detail.

Beck et al. (1978) begin their analysis by imputing "individualistic" assumptions of perfect competition and labor market

This research was supported by the National Institute of Mental Health (Grant No. MH-06275). NORC-GSS data were obtained from the Data and Program Library Service of the University of Wisconsin–Madison. Computations were carried out using facilities of the Center for Demography and Ecology, provided with core support from the National Institute of Child Health and Human Development (Grant No. HD-05876). I thank Shu-Ling Tsai for extensive and careful research assistance. E. M. Beck has kindly responded to my requests for additional information about his research. I thank Glen Cain, O. D. Duncan, Neil Fligstein, Arthur S. Goldberger, Charles Halaby, Susan Janssen, Arne Kalleberg, Robert Kaufman, Robert D. Mare, William Mason, Rachel Rosenfeld, Aage Sørensen, Seymour Spilerman, Bruce Stephenson, and Ross M. Stolzenberg for their helpful reactions to an earlier draft of this paper.

homogeneity to research in the "neo-classical" human capital and status attainment traditions. The economists can speak for themselves; for an enlightening statement, see Cain (1976). I think that the theoretical assertions about status attainment research are patently inaccurate. For example, in the sociological works cited by Beck et al. (p. 705) as "individualistic in orientation and execution"—Hauser and Featherman (1977), Sewell and Hauser (1975), and Duncan et al. (1972)—one need not look far to find analyses of heterogeneity in the attainment process across populations defined by such variables as race, sex, age, calendar year, city size, and migration status, whose sociological explanation is not "tied directly to the characteristics brought into the marketplace by the individual workers" (Beck et al., p. 705). Far from assuming fully competitive and homogeneous labor market processes, a major thrust of recent stratification research has been to demonstrate the variety of social and psychological mechanisms (extending over the life cycle and affecting major social groups in different ways) which tend to complicate and to invalidate such narrow theoretical frameworks.

The representation of labor market sectors in earnings functions is a straightforward theoretical and empirical elaboration of previous status attainment models (Featherman and Hauser, 1978: chap. 9). In fact, the Duncan SEI (Reiss, 1961) incorporates a much larger number of distinctions of socioeconomic standing by industry within occupation than does the prestige scale employed by Beck et al. (1978). However, in attempting to elucidate the effects on earnings of industrial sectors as defined by Beck et al., I do not want to imply my agreement with their concept that there are just two economic sectors, with their assignment of each industry to "core" or "periphery" sectors, nor with their use of industries, rather than firms, to designate labor market sectors. I suspect that important interfirm and interindustry differences in earnings are obscured in the analysis of Beck et al.

To avoid confusion, I use "sectoral interaction effects" to refer to differences in slopes in semilogarithmic earnings functions, like those in the left-hand panel of Table 3 of Beck et al. (1978:713). I do not refer to "real dollar" differences in the effects of variables as interaction effects. In this respect I believe that I am following the intent of Beck et al. (see p. 712, par. 3 and 4, and p. 714, par. 3 and 4). However, they also take note of "real dollar" differences in effects at some points in the text (pp. 714, 715, 717). In the semilog earnings function, each unit change in a regressor leads to a proportionate change in earnings, so the effect of a regressor in dollars depends on the value of the regressor at which its effect is evaluated (and on the values of other variables in the function). In the dollar earnings function, each unit change in a regressor leads to the same change in dollar earnings, regardless of the value of the regressor (or of other variables in the function). In the population, so long as sectors differ in intercepts of the earnings function, constant nonzero slopes in the semilog functions imply differences in real dollar effects, and constant nonzero dollar effects imply different slopes in the semilog functions. If one accepts both forms of interaction as evidence of heterogeneity in the labor market process, it is not logically possible to reject the hypothesis of heterogeneity.

There are good reasons to choose the semilog form of the earnings function, which is widely applied in economics and sociology. First, it has a convenient interpretation—that variables have proportionate effects on earnings. Under some circumstances, such effects can be interpreted directly as rates of return (Mincer, 1974). Moreover, one may expect proportionate effects to be invariant with respect to global price and productivity changes (or even to changes in units of currency across societies), while effects in raw units of currency will not be invariant. Second, the semilog form of the earnings function has desirable statistical properties relative to the linear (dollar) form. The residuals (deviations from the regression line) are typically less skewed and less heteroscedastic when the semilog function is applied. There is also evidence that the semilog function fits earnings data better than the linear (dollar) function or other power functions of earnings (Heckman and Polachek, 1974).

It is unfortunate that Beck et al. identify heterogeneity in labor market processes with heterogeneity in regression slopes, for that identity holds only where there is a strong theoretical justification for the functional form in which heterogeneity appears. For example, the statisticians Mosteller and Tukey (1977) invoke parsimony as a criterion in the choice of functional forms; a researcher may radically transform a dependent variable in order to obtain good fit with a simple function of explanatory variables. In the context of such a flexible statistical analysis, heterogeneity of slopes is but a methodological nuisance. Obversely, one might infer substantive heterogeneity from functions with homogeneous slopes.

In my view, Beck et al. (1978) offer no substantial theoretical rationale to predict the occurrence or form of a specific statistical interaction in their regression analysis. Moreover, they provide no theoretical rationale for semilog or linear forms of the earnings function that would support the inference of heterogeneity in the earnings process, regardless of empirical findings. Indeed, while Beck et al. use a semilog function to argue for sectoral heterogeneity, the same authors elsewhere use a linear function to make the same argument (Tolbert et al., 1980).

Beck et al. (1978:711) report that the mean logarithm of earnings is 8.5993 in the core with a standard deviation of 2.1148, and the mean is 7.7706 in the periphery with a standard deviation of 2.5628. These numbers are not credible. For example, they imply that 1975 dollar earnings at the mean in the core are $5,428 (= $e^{8.5993}$); earnings at the mean in the periphery are $2,370. As a rough approximation, the log of earnings is normally distributed; thus, one would expect dollar earnings at the mean of the distribution of the log of earnings to fall near the median of the distribution of dollar earnings. In the cumulative codebook of the GSS, the median current dollar earnings of respondents are roughly $7,400 in the 1975 and 1976 GSS (NORC, 1977:45). Even in the core the figure reported by Beck et al. is about $2,000 less than one would expect from the assumption of lognormality. That is not all. At one standard deviation above the mean, their figures imply annual earnings of $44,986 in the core and $30,742 in the periphery; the highest category in the NORC (1977) earnings reports is "$25,000 or more." At one standard deviation below the mean they imply annual earnings of only $655 in the core and $183 in the periphery. Something is wrong.

What accounts for the anomalously low means and large standard deviations in the distributions of the log of earnings? One reason to take the log of earnings is to reduce the positive skew of the distribution. In compressing the high end of the dollar metric, the logarithmic transformation also stretches out the low end of the distribution (Mosteller and Tukey, 1977:chap. 4). Thus, the anomalies might be explained by observations of no earnings or very low earnings. Since the log of zero is undefined, it is common practice to assign $1 (or some other nominal sum) to zero earners before taking logs. When $1 is assigned, the log is 0 by construction. This rule of thumb may generate extreme outliers (see Jencks et al., 1979:283–4, 374–5). There are a number of better practices: add a larger nominal value (for example, $500 or $1,000) to each observation; use a functional form which gives special treatment to zeros (Tobin, 1958; Sewell and Hauser, 1975:chap. 6; Goldberger, 1964:253–5); ignore the outlying observations (Featherman and Hauser, 1978:chap. 5); or choose a less radical transformation of earnings (Jencks et al., 1979:283–4).

The GSS (NORC, 1977) uses a closed-ended question to ascertain earnings in the calendar year before the survey date. Each respondent chooses a broad income category from a card offered by the interviewer. The lowest category on the card is "under $1,000." Even if one assumed a uniform earnings distribution from $0 to $1,000, the midpoint of the interval would be $500. If log(500) = 6.21 were the minimum of the distribution of the log of earnings, it could not account for the anomalous observations.

There are 99 assigned values of zero in the distributions of the log of earnings used by Beck et al. (Beck has acknowledged this in a private communication.) Moreover, these assigned values of zero do not occur primarily (or even secondarily) among persons holding low-paying jobs in the year before the survey date. They occur among persons who did not work at all in the year before the survey date or who changed occupations between the end of that year and the survey date (usually in March or April). Not only do the values of zero on the log of earnings give the distribution extreme negative skew, but the outliers have no clear connection with the occurrence of low pay.

The documentation of the GSS (NORC, 1977) suggests how Beck et al. (1978) made this error. By assigning zeros to the log of earnings in certain cases from the GSS, I have been able to approximate their results rather closely. When the observations with assigned zeros are removed from my analysis, the anomalies disappear. So do major findings of Beck et al.

In the 1975 and 1976 GSS (NORC, 1977), respondents were classified as in the labor force if they (1) were employed full or part-time, (2) had a job but were not at work, or (3) were unemployed (NORC, 1977:13, Q. 1). These and other persons with work experience were asked about their present or past occupation: "What kind of work do you (did you) normally do? That is, what (is/was) your job called?" (NORC, 1977: Q. 2-A, p. 15). At Q. 35, respondents were asked (NORC, 1977:44–5):

> 35. Did you earn *any* income from (OCCUPATION DESCRIBED IN Q. 2) in [1972/73/74/75/76]?
>
> Yes . . . . (ASK A)
> No . . . . [See *REMARKS*]
>
> A. *IF YES:* In which of these groups did your earnings from (OCCUPATION IN Q. 2) for last year—[1972–1976]—fall?

> That is, before taxes or other decuctions. Just tell me the letter.
>
> [HAND CARD E]
>
> *REMARKS*: Card E contained responses for punches 01–12 only. Q. 35 responses are not in these data, but are contained in Q. 35-A.

Question 35 states that persons with no earnings from the occupation described in question 2 were not asked to report personal earnings in the previous year; their earnings were coded as "blanks" for "not applicable" in the GSS file. Limitation of the personal earnings question to earnings in the named occupation is reinforced by the interviewer instructions (NORC, 1977:179):

> *1976*
>
> Note instruction: SEE Q. 2. IF ANY OCCUPATION RECORDED, ASK Q. 35. Read job title from Q. 2. Record R's income only from job described in Q. 2, not from any other jobs or sources. This question is concerned with OCCUPATION, rather than specific job or employer. EXAMPLE: If R's occupation was "waitress," you would ask for total income in 1975 as a waitress . . . even if she worked in several different places during the year.
>
> *1974–75*
>
> NOTE INSTRUCTIONS. Read job title from Q. 2. This question is concerned *only* with any income R. earned from occupation described in Q. 2, not any other income from other sources or income of other family members.

Beck et al. (1978) treated current members of the labor force who had no earnings in the named occupation in the previous year as if they were zero earners by replacing "blanks" in the dollar earnings variable with zeros in the logarithmic transformation of earnings. This procedure implies that persons who were not in the labor force at all in the previous year were treated as extreme low earners in that year. It implies that persons who changed occupations after the beginning of the survey year were treated as extreme low earners in the previous year. It implies that persons who changed occupations during the previous year had only part of that year's earnings covered by the GSS personal earnings question. To be sure, some persons may have been unemployed throughout the previous year and thus have been classified legitimately as in the labor force but without earnings in that year. I think that such persons are small in number, relative to those improperly classified as nonearners, and it would in any event be questionable to assign zeros to such persons on the log of earnings.

Unfortunately, the GSS (NORC, 1977) data lack the information required to enumerate persons properly and improperly classified as nonearners. Given the broad and heterogeneous make-up of the sample selected by Beck et al. (1978), which included all women in the labor force at the survey date and did not impose an upper age limit, I think it probable that most nonearners were improperly classified. Of 1,695 GSS respondents in the labor force at the survey date, Beck et al. (p. 708) excluded 12 for whom industry was not reported. Of the remaining 1,683 persons in their sample, 99 were assigned "blanks" on personal earnings in the previous year—53 in the core and 46 in the periphery.

Some light is shed on the validity of the classification of nonearners by the GSS item on work stability (NORC, 1977:123, Q. 132):

> At any time during the last ten years, have you been unemployed and looking for work for as long as a month?

Among the 99 current members of the labor force with "blanks" on earnings in the previous year, 53% (53 cases) reported a spell of unemployment as long as one month in the previous decade. In the unlikely case that *all* of these "unstable" workers had been unemployed throughout the previous year, only 53 cases would properly have been classified as unemployed nonearners. I believe this is an unreasonably high upper bound on the number of persons properly classified as nonearners, for 32% of earners also reported a one-month spell of unemployment in the past decade.

The treatment of the 99 zero earners in the labor force, who make up less than 6% of the sample used by Beck et al. (1978), has a critical effect on the results. For example, Table 1 shows the means and standard deviations of variables used in my reanalysis of the GSS data. LNY1 is my approximation of the dependent variable employed by Beck et al. That is, I adjusted the 1974 data to 1975 dollars, placed missing observations at the mode, assigned each person the log of the midpoint of his earnings interval, and used a Pareto approximation to estimate the mean of the upper, open-ended interval; the 99 observations with zero earnings were assigned zero values on LNY1. In the case of LNY2, the procedures were the same, except that the 99 observations with zero earnings were ignored. The characteristics of LNY1 are very similar, though not identical to those of the earnings measure used by Beck et al. (p. 711). I have found other discrepancies in my reanalysis, but I think their effects are minor. The means and standard deviations of LNY2 are vastly different from

Table 1. Means and Standard Deviations of Characteristics of Workers in the Civilian Labor Force by Industrial Sectors: 1975 and 1976 NORC General Social Surveys

			Industrial Sector	
Worker Characteristic		Total N = 1683	Core N = 1125	Periphery N = 558
LN annual earnings	LNY1[1]	8.349	8.616	7.809
		(2.295)	(2.103)	(2.558)
	LNY2[2]	8.870	9.042	8.511

		(3.895)	(3.930)	(3.787)
Father's prestige	X_{14}[9]	38.906	39.404	37.871
		(12.216)	(12.478)	(11.599)

[1] Cases with "zero" earnings are assigned LNY1 = 0, and missing earnings data are assigned the modal value, $12,500 ($N_T$ = 1683, N_C = 1125, N_P = 558).

[2] Missing earnings data are coded as $12,500, but cases with "zero" earnings are excluded (N_T = 1584, N_C = 1072, N_P = 512).

[3] 2 missing data for male ages are coded as 27 or 25 for core or periphery sectors, respectively (N_T = 1004, N_C = 709, N_P = 295).

[4] 3 missing data for female ages are coded as 24 or 25 for core or periphery sectors, respectively (N_T = 679, N_C = 416, N_P = 263).

[5] 4 missing data excluded (N_T = 1679, N_C = 1122, N_P = 557).

[6] 4 missing data excluded (N_T = 1679, N_C = 1121, N_p = 558).

[7] 7 missing data excluded (N_T = 1676, N_c = 1120, N_p = 556).

[8] Parental education is taken as the years of schooling for the respondent's father. If this information is not available, data for mother's education or modal values were substituted, using an algorithm provided by Beck et al.

[9] 200 missing data excluded (N_T = 1483, N_C = 1001, N_P = 482).

those of LNY1 in both the core and the periphery. For example, in the core sector, dollar earnings at the mean of LNY2 are $8,451, compared to $5,519 in the case of LNY1. At one standard deviation above the mean, earnings based on LNY2 are $20,517, but they are $45,207 when based on LNY1. At one standard deviation below the mean, earnings based on LNY2 are $3,481, but they are $674 when based on LNY1. Similar results are obtained in the periphery, where earnings at the mean of LNY2 are $4,969, and they are $2,463 at the mean of LNY1. At one standard deviation above the mean in the periphery, earnings based on LNY2 are $14,501, and those based on LNY1 are $31,793. At one standard deviation below the mean, earnings based on LNY2 are $1,703, and those based on LNY1 are $191.

In core and periphery, the standard deviation of LNY2 is less than half as large as that of

LNY1. In the total sample, earnings at the mean of LNY2 are $7,115, a figure reassuringly close to the median current dollar earnings of $7,400. In the total sample, earnings at the mean of LNY1 are only $4,226. Thus, the presence of (inappropriate) zero observations accounts for anomalous characteristics of the earnings measure used by Beck et al. (1978).

To answer the question, "How do the zero observations affect the regression analysis?" I carried out new regression analyses of earnings in the core and the periphery, first, using all observations with LNY1 as the dependent variable, and, second, using observations with nonzero earnings and LNY2 as the dependent variable. I did not reanalyze the earnings of the subsample of full-time employed white males (Beck et al. 1978:716), nor did I reanalyze the linear probability function that Beck et al. used to estimate the incidence of poverty-level earnings (pp. 713, 716). I do not think a reanalysis of earnings in the male subgroup would add anything of substance to the present analysis; Beck et al. have provided their tabulations for that subgroup that show the same anomalies as their published tabulations for the full sample (p. 716). The incidence of poverty-level earnings, like the overall distribution of the log of earnings, is affected substantially by the inappropriate classification of job changers and persons outside the labor force as nonearners or low earners. Also, statistical defects in the linear probability function are well documented, and these are likely to be important in analyses of a highly skewed variable like the incidence of poverty.

Table 1 reports the means and standard deviations of variables used in my reanalysis of the GSS (NORC, 1977) data; the reader should compare it with Table 2 of Beck et al. (1978:711). For most variables the two analyses yield the same estimates. As noted in the table, I reproduced Beck et al.'s results for age by assigning modal values to a small number of missing observations; this procedure was not mentioned by Beck et al. I was unable to resolve a minor discrepancy in the proportion of persons with a high school or junior college degree. In the core sector my estimate of mean occupational prestige is larger, and its standard deviation is smaller than that of Beck et al. That discrepancy apparently occurred because the prestige distribution used by Beck et al. included four zero values, which are out of its legitimate range, and I dropped these from the analysis.[1] In the case of work stability I excluded nonresponses, which Beck et al. apparently did not do.

"Father's occupational prestige" deserves special mention. My estimates of its mean are smaller and my estimates of its standard deviation are larger than those of Beck et al. (1978). They randomly assigned one of three modes of the prestige distribution to substitute for missing data, so their result cannot be reproduced independently (p. 708).[2] My estimates were obtained by dropping the 200 cases where father's prestige was missing. Aside from the large number of missing observations, parental prestige had trivial negative effects and did not interact with economic sector in the earnings regressions (p. 715). For these reasons, I dropped it from the regression analysis.

Beyond the differences just noted, I have tried to repeat the analysis of Beck et al. (1978) for each version of the dependent variable (LNY1 and LNY2). In particular, I have not tried to improve the specification of the earnings function in other ways. I believe that several defects in specification remain, so my results are of interest mainly because of their differences from those of Beck et al. For example, there is ample theoretical and empirical evidence that a linear term in age does not adequately represent the effect of work experience on earnings, especially in a sample with no upper age limit.

Aside from lifetime work experience, it is also important to include more proximate measures of labor supply (that is, weeks and hours worked) in the earnings function. No such measures were obtained for the previous year in the GSS, yet it is reasonable to expect that differences in labor supply are intricately connected with sectoral differentials in earnings, as they are with sex and race differentials in earnings. This is not to say that differences in labor supply between labor market sectors or between population subgroups are either voluntary or exogenous; rather, the several mechanisms affecting labor supply are quite different from those to which Beck et al. (pp. 706–8) allude in predicting sectoral interaction effects and earnings differentials.

It is well established, also, that occupational socioeconomic status is superior to occupational prestige in representing occupational differences in earnings. Last, heterogeneity in earnings functions across major social groups (race, sex, age, and geographic location) has been a major focus of research. While Beck et al. do attempt to show sectoral heterogeneity among full-time white male workers, it is curious that they do not specify heterogeneity in the regressions by race or sex within labor market sectors. Indeed, were there not other reasons to question the validity of their regression analysis, it would be pertinent to ask whether differences in the race and sex composition of the core and periphery sectors may help to explain the observed heterogeneity across sectors in the function specified by Beck et al.

---

[1] According to Bruce Stephenson of NORC, these four cases were persons who reported jobs whose descriptions could not be coded.

[2] In order to base my analysis on an exact replication, I had hoped to work with the data file used by Beck et al. (1978). While Beck expressed his willingness to share that file with me, it had accidentally been destroyed some time before I asked for it.

Table 2 shows the results of my efforts to reproduce the earnings regressions of Beck et al. (1978) using LNY1. Columns (a) and (b) of Table 2 show the earnings regressions in the core and periphery, respectively. Despite the differences between our analyses, my estimates are very similar to those reported by Beck et al. (p. 713). Column (c) reports estimated slopes in a pooled equation, where intercepts differ in the core and periphery, but common (homogeneous) slopes are estimated. This equation is not reported by Beck et al., but it is reassuring that the coefficients of male age, occupational prestige, union membership, and work stability do resemble the common slopes for those variables reported by Beck et al.

I also estimated a single pooled equation in which each sector has unique slopes and intercepts. Of course, the estimated slopes from the equation merely recapitulate the findings reported in columns (a) and (b). Column (d) shows F-statistics for the heterogeneity in

slope of each variable in the pooled equation with unique slopes. Also, the base of column (d) reports summary measures of fit of the equation with unique slopes.

While I think it fair and accurate to say that the results in columns (a), (b), and (c) reproduce the major features of the analysis by Beck et al. (1978), there are significant departures from their findings about sectoral interaction and about the fit of the regression equation. (I am discussing my effort to reproduce their findings, not the effect of including misclassified nonearners in the regression analysis.) Column (e) of Table 2 reports the findings of Beck et al. with respect to sectoral interaction in their semilogarithmic earnings function. Beck et al. say that they reject the null hypothesis of homogeneity when interactions are significant at or beyond the $p = .10$ level (pp. 712–3), assuming the GSS is as efficient as a simple random sample (NORC, 1977:157). My analysis follows the same generous rule, but in three of the nine cases where Beck et al. report sectoral interactions (sex, high school, and postgraduate degree) my test statistics fall well below their critical values. These discrepancies also appear when I construct a t-statistic from the point estimates and standard errors of the slopes in equations (a) and (b). I have been unable to resolve them.[3] Incidentally, Beck et al. (p. 713) report $R^2 = .2962$ in an equation containing only the significant sectoral interaction effects, while I find $R^2 = .192$ in an equation containing all sectoral interaction effects. Beck has informed me that $R^2 = .2008$ in his analysis; the larger figure was obtained by correlating observed dollar earnings with the antilog of predicted log earnings.

One other anomaly in the findings reported by Beck et al. (1978:712–3) is that their F-ratios for the Chow test, purporting to be a global test for 14 possible sectoral differences in slopes, also include the effects of differences in intercepts between sectors. Thus, while there are only 14 independent slopes in each of the sectoral regressions, Beck et al. (p. 713) report 15 degrees of freedom for the numerator of each of the F-ratios. Beck et al. (p. 714) wrongly interpret the results of these tests as if they reflected only sectoral interaction effects.

Table 3 shows a regression analysis of the log of GSS earnings from which the 99 observations assigned zero values have been dropped. In every other respect the analysis is unchanged, but the results differ dramatically from those reported earlier in Table 2 and from those reported by Beck et al. (p. 713).

First, the fit is vastly improved. As shown by the standard errors of estimate and coefficients of determination, the predictive value of the simple earnings function is substantially greater in the core, in the periphery, and in the total sample. For example, the pooled equation with interaction effects accounts for 19.2% of the variance in LNY1 and for 38.6% of the variance in LNY2; the unexplained variance of earnings is more than seven times larger in the case of LNY1 than in that of LNY2 ($2.079^2/.776^2 = 7.2$).

Second, when the outliers are dropped, there remain only two statistically significant interaction effects. The (negative) effect of parental schooling is significantly larger in the periphery than in the core. While this negative effect is statistically significant in the periphery and in the total sample, the sign of the coefficient makes no theoretical sense. I am inclined to regard that finding as evidence of measurement error—possibly the treatment of missing data—in parental schooling, or as evidence of misspecification elsewhere in the earnings function. Beck et al. (1978) also have little to say about a parallel finding in their analysis.

More interestingly, the estimated effect of occupational prestige is more than twice as large in the periphery as in the core. This is the only interaction effect in my Table 3 which may be worth interpreting, and it was not detected in the analysis by Beck et al. (1978:713, 715) nor in that of my Table 2. Both in the core and in the periphery the effects of prestige on earnings are substantial. Earnings increase by 1.1% for each unit of prestige (on the NORC scale) in the core, and they increase by 2.5% for each unit of prestige in the periphery. These different returns may be a result of nonlinearity rather than of heterogeneity, for jobs in the core and in the periphery cover different ranges of the prestige scale. Mean prestige is 42.3 in the core and 33.4 in the periphery; the two means are nearly a standard deviation apart. I have not investigated this possibility, that the sectoral interaction effect of prestige is an artifact of nonlinearity.

In the theoretical context developed by Beck et al. (1978), I think it may be difficult to explain why the effects of prestige are twice as large in the periphery as in the core. For example, Beck et al. write (p. 707):

> Theories of dual economy suggest that these sectoral differences have important implications for the opportunity structures and experiences faced by individual workers. In the core sector, workers move within job structures characterized by differentiated task and wage schedules with often well-defined career patterns, i.e., internal labor markets (Doeringer and Piore, 1971; Spilerman, 1977). Formal education is widely used to mediate

---

[3] Beck has not responded to my inquiries about these discrepancies.

> individual access to job ladders, and workers' wages "are largely determined by their respective access to different job clusters, by the relatively rigid pattern of wages attached to the job structures through which they respectively move, and by the speed with which they pass through those structures" (Gordon, 1972:50). In the peripheral sector, occupational opportunity structure is more restricted [sic] with a consequent dampening of task and wage variations. Gordon (1972:51) suggests that in this sector, "variation in individual hourly wages will depend very little on variations in individual 'capacities' like aptitude, reasoning and vocational skill."

Whatever the theoretical ramifications of the differential effects of prestige, I think it would be premature to draw global conclusions about heterogeneity in labor markets from my finding that occupational prestige affects earnings more in the periphery than in the core.

Again, aside from the effects of occupational prestige and of parental schooling, the analysis in my Table 3 detects no statistically significant interaction effects. This may be contrasted with nine sectoral interactions reported by Beck et al. (of which I was able to confirm only six). Some of the noneffects are worth mentioning. Beck et al. (p. 715) suggest that "earnings return to education in the core sector rests on the acquisition of a formal degree, whereas in the peripheral sector economic benefits are derived from additional years of schooling, not from increases in formal levels of certification." In the analysis of my Table 3, the linear term in schooling is not significant in core or periphery, and the effects of levels of certification do not differ across sectors. Beck et al. (pp. 717–8) also write:

> We further contend that the sectoral model employed here constitutes an essential element in understanding the process of discrimination against minority groups in that it includes not only individual factors but also the organization of the economic structure. Specifically, despite the differential representation of females and nonwhites in the peripheral sector, there is no statistically significant evidence of earnings discrimination in that sector after controlling on the predetermining variables. In the core sector, however, there is evidence of significant adverse race and sex main effects on earnings even after controlling on human capital and occupational variables.

In the analysis of my Table 3, women suffer a very large economic disadvantage, which is not significantly different in the core and in the periphery. Furthermore, with the other variables controlled, nonwhites have no significant advantage or disadvantage in the core or in the periphery, nor do the estimates of the effect of race differ significantly between the core and the periphery.

Not only are most of the revised estimates in my Table 3 similar in the two economic sectors, but they are very different from those estimated in my Table 2 and, similarly, from those estimated by Beck et al. (1978:713). I offer a few illustrations constructed by taking antilogs of coefficients from the revised equation with common slopes (col. [c] of my Table 3) and from the unique sectoral equations estimated by Beck et al. (p. 713). Beck et al. estimate that women make 44% ($e^{-.8232} \times 100$) as much as men in the core and 87% as much in the periphery; in Table 3 I find that in both sectors women make 55% of the earnings of men. Beck et al. estimate that nonwhites make 63% as much as whites in the core and 38% more than whites in the periphery. In Table 3 I find no differences between the earnings of whites and nonwhites—a seemingly anomalous finding which may be a result of the inclusion of both men and women in the analysis without a measure of labor supply. Beck et al. estimate that the currently unemployed made 50% as much in the previous year as the currently employed in the core, and the currently unemployed made 14% as much in the previous year as the currently employed in the periphery. In Table 3 I find that the currently unemployed made 85% as much in the previous year as the currently employed. My reading of these comparisons is that the estimates based on Table 3 are reasonably consistent with other social scientific findings, but those of Beck et al. are not.

Conclusion

Beck et al.'s analysis of sectoral differences in earnings, based upon data from the 1975 and 1976 NORC General Social Surveys, is fatally flawed. Because of an error in sample selection, many job changers and persons out of the labor force were treated as if they worked but had no earnings. This error was compounded by using a logarithmic transformation of earnings, which gives a great deal of importance to observations at or near the zero point of the transformed variable. Because of this error, their analyses of earnings (but not of labor force composition) are wrong in important respects. In this reanalysis of the GSS data I have emphasized the effect of the error upon Beck et al.'s major conclusion, that the earnings process is heterogeneous across industrial sectors. When the error is corrected, most of the evidence of heterogeneity disappears.

To be sure, there remain differentials in earnings between core and periphery sectors. In the corrected equation of my Table 3 (col. [c]), where common slopes are estimated in the two industrial sectors, I estimate that workers in the periphery make 83% as much as workers in the core; the differential is $1,455 when evaluated at the mean of the earnings distribution in the core, and it is $1,033 when evaluated at the mean of the earnings distribution in the periphery. Any resemblance between these dollar figures and the estimates of Beck et al. (1978:713, Table 4) is purely coincidental. The equations used by Beck et al. to standardize earnings between sectors vastly overestimate the sectoral earnings differential in relative terms, but this error is largely compensated by erroneously low estimates of average earnings in both sectors.

Another respect in which the analysis of Beck et al. (1978) is roughly correct is the share of the total sectoral earnings differential which is explained by the variables included in their regression equation. In my revised estimates the difference in the log of earnings between periphery and core is −.531; evaluated at the means in the two sectors, the difference is $3,482. Since the coefficient of sector in the pooled equation of my Table 3 is −.1889, differences in social composition between sectors explain about two-thirds of the initial difference in earnings.

These points of agreement are conditional upon the specification of the earnings functions in my Table 3. While I believe they do not share the flaws of the equations estimated by Beck et al. (1978), there remain several specification errors in those equations. In particular, I think that the absence of a proximate measure of labor supply (the amount of time at work in the previous year) explains part of the remaining sectoral difference in earnings.

I doubt that any commentary can counter the impact of the broad and sweeping conclusion of Beck et al. (1978:717):

> In face of strong empirical evidence contrary to the implicit tenet of labor market homogeneity, parameter estimates which are conditional on this assumption can no longer be treated as appropriate bases for the construction of sociological theory or social policy.

It is most regrettable that their proposition finds so little empirical support.

SOCIAL STRATIFICATION IN INDUSTRIAL SOCIETY: FURTHER EVIDENCE FOR A STRUCTURAL ALTERNATIVE*

(REPLY TO HAUSER)

In 1950 two young researchers characterized the dominant community stratification research tradition as follows:

> There are numerous indications that the principal motivation of many crucial points of the analysis is more a matter of the imposition of a set of categories and the manipulation of a technique than the understanding of what is at stake—the social structure. This point is evidenced by a general tendency to regard any anomalies encountered as being problematic only in a methodological light, rather than from the standpoint of the theory of class structure. There is often a failure to consider the meaning of negative instances, or to consider alternative hypotheses. (Pfautz and Duncan, 1950:211)

Now, some thirty years later, Professor Hauser's defense of the dominant status attainment research tradition founded by Duncan completes the circle.

In attempting to counter our theoretical and empirical criticisms of the status attainment tradition, Hauser reinterprets our work from within that neoclassical theoretical perspective which status attainment presumes. From that vantage, Hauser sees no basic conceptual or theoretical issues, on y methodological errors and empirical anomalies. In our response we will examine both the conceptual foundations of Hauser's assertions and their empirical validity.

---

* Direct all communications to: E. M. Beck; Department of Sociology; University of Georgia; Athens, GA 30602.

Because confusion between conceptual and methodological issues permeates Hauser's comment, we must give some initial attention to the rather different theoretical foundations for his status attainment research and for our research on industrial segmentation. Status attainment rests on a neoclassical theoretical perspective (Horan, 1978) in which the socioeconomic structure of industrial society derives from rational interactions of individual workers and individual employers within a competitive market setting. Social stratification is represented as an individual "attainment" process and that process is analyzed in terms of the socioeconomic returns to individual characteristics, such as family background and schooling. Hauser defends this tradition by acknowledging heterogeneity in status attainment processes by race, gender, and age. Such an acknowledgement misses the mark. The important issue is how such differences are conceptualized and interpreted. What is the theory of stratification in industrial society which would lead one to expect such differences? Our position is not only that labor market heterogeneity exists, but that it derives from the organization of production in industrial capitalism. It is this conceptual grounding which distinguishes industrial segmentation theory from simple demographic observation by providing an alternative interpretative scheme for understanding the operation of the stratification system.

Our research derives from a very different conception of the social and economic order than that which underlies status attainment. From our perspective, the placement of individuals within the social order cannot be understood solely in terms of the personal characteristics of the individuals themselves. It is the organizational structure of industrial capitalism which shapes the American stratification system, not the psychological dispositions or individual predilections of workers. Accordingly, the fundamental issue in social stratification is not individual "attainment," but the arrangement of distinct social positions within the social and economic organization of production, and the impact such arrangements have on the experiences of individuals.

These different perspectives can lead to divergent interpretations of the same empirical findings. When faced with evidence that individual attainment processes are different for blacks and females, status attainment researchers acknowledge these differences and proceed with a research tradition which concentrates primarily on white males. When faced with the existence of low earnings, poverty, and underemployment, status attainment researchers tend to characterize these as representing individual "outliers" and to exclude them from analysis. From our view, the differential experiences of females and blacks, and the existence of poverty and underemployment are not anomalies but regularities which can be better understood through a focus on the social and economic structure of industrial capitalism.

Given the fundamental intellectual differences between the status attainment perspective and our own, we find Hauser's systematic misapprehension of our work to be predictable. In our response to his specific criticisms we will focus on two separate themes: (1) What are the theoretical implications of Hauser's "methodological" criticisms? (2) Do the data manipulations proposed by Hauser eliminate the existence of substantial sectoral differences in individual-level earnings determination processes?

The NORC Income Question

Hauser identifies an important issue concerning the use of the NORC General Social Survey for analysis of earnings determination models; namely, the income question is keyed to "normal" occupation ("What kind of work do you [did you] normally do?") and thus may not accurately reflect earnings. Specifically, individuals classified as nonearners by the GSS and treated as such in our analysis may in fact have earned income in some other occupation. Hauser "think[s] it probable" that respondents who report no earnings should not be treated as nonearners. We think it probable that our treatment of these individuals as nonearners was accurate. However, as Hauser (1980:705) notes, "the GSS data lack the information required to enumerate persons properly and improperly classified as nonearners." Hauser proposes to resolve the issue by deleting the nearly 6% of the sample who fell into the nonearner category.[1] This is a conceptually and empirically inappropriate truncation of the sample which renders his subsequent analysis meaningless.

It should be clear that this dispute about the classification of nonearners cannot be settled through further manipulations of the NORC data, since any such manipulation must impose some prior solution to the classification issue. In order to evaluate the empirical validity of Hauser's criticisms, it is necessary to employ a national data set which does not have the problems associated with the NORC income questions: the 1976 Current Population Survey (March Supplement). From this CPS we selected all workers who were members of the recently experienced civilian labor force in 1975.[2] This produced a sample of over 62,000 respondents, representing almost 100.3 million workers. We will use these data to evaluate each of Hauser's claims about "errors" in our analysis, errors which Hauser claims are responsible for our findings of significant differences in the earnings determination process between core and periphery economic sectors.

---

[1] Although Hauser claims his study is a replication, this is not accurate. He redefines the sample and deletes one of the variables included in our original analysis, all of which results in the loss of a substantial number of degrees of freedom. We do not know to what degree his conclusions were affected by these departures.

In order to evaluate these claims we estimate, under a variety of conditions, an augmented Mincer-type human capital function by industrial sector. This human capital function consists of linear and quadratic terms for years of schooling and years of work experience, a schooling/work experience interaction term, and an occupational prestige variable.[3] To determine the robustness of sector differences we computed a Chow test for sectoral interactions under each of the conditions proposed by Hauser. The results of these analyses, presented in Tables 1 and 2, demonstrate that none of the "methodological" issues proposed by Hauser eliminate the sectoral differences in earnings determination processes which we noted in our original paper.

In discussion below we consider each of Hauser's specific criticisms, focusing first on the theoretical implications of the criticism and second on its empirical validity.

Labor Supply vs. Labor Demand.[4] Hauser offers that the earnings equation should contain annual hours worked as a labor supply variable and that its omission is a serious flaw. While such a specification *may* be reasonable from a human capital perspective, it represents a serious conceptual misspecification from our perspective. Specifically, there is no reason to assume that annual hours worked reflects labor supply as opposed to labor demand factors. If each individual labor force participant elects how many hours to work (that is, if time worked is a consequence of individual decision making), then a control for this as a supply factor might be appropriate. However, if the number of hours worked is largely determined by factors beyond the individual worker—determined by the same elements of the social and economic organization that structure socioeconomic rewards—then, time worked is not a labor supply factor but a characteristic of labor which is endogenous to the organization of production.

Furthermore, the control on time worked which Hauser advocates would change the focus of analysis from earnings determination to wage determination.[5] That is, since earnings is the product of a wage-rate factor and a time-worked component, the elimination of differences in time worked leaves only one source of variation in earnings: wage rates.[6] Earnings determination models which include time worked as a control variable, therefore, amount to implicit wage determination models. While such a shift from earnings to wage determination is consistent with the neoclassical human capital theory of Becker and Mincer, it is not the correct specification for the theory we are employing.

Not only does Hauser's labor supply approach do violence to segmentation theory, but it leads to the blind dismissal of the effects of unemployment and underemployment on socioeconomic outcomes. By concentrating on models of wage determination, or restricting models of earnings determination to full-time year-round workers, much research in the status attainment tradition has naively ignored the very real problems of underemployment, especially for minorities, and the critical adverse effects these have on socioeconomic rewards.[7] While it is possible to conceptualize

---

[2] The recently experienced civilian labor force is defined as workers who in 1975 were civilians 16 years old or older and were employed, either full time or part time, or were a member of the recently experienced unemployed. The recently experienced unemployed are those who did not work in 1975 but who sought employment and who had been employed for two consecutive weeks or more during the previous four years.

[3] A complete discussion of the variables, as well as a justification of the functional form, is detailed in Beck et al. (1980).

[4] For a more elaborate discussion of these issues, see Beck (1980).

[5] Blinder (1976) makes an important point by noting that such a transition to a wage determination model implies theoretical interest in potential earnings rather than actual earnings. Our interest was in the latter.

[6] One strategy which we are exploring is to decompose log earnings into its additive elements, a log wage-rate component and a log time-worked component, and then treat these as jointly dependent endogenous variables in a simultaneous equations system. This approach permits an assessment of the effects of exogenous factors on both components of annual earnings and avoids the limited scope of pure wage determination models.

[7] For a discussion of these issues see Fusfeld (1973), Gordon (1972), Harrison (1972), Hiestand

Table 1. F-Tests for Segmented Market Model[1]

Labor Income	White Males	White Females	Nonwhite Males	Nonwhite Females
Unadjusted for Labor Force Participation				
Dollar Earnings	187.76*	153.52	29.23	20.46
Ln Earnings	129.33	108.20	10.27	7.08
Adjusted for Labor Force Participation				
Dollar Earnings	142.52	89.99	19.62	15.57
Ln Earnings	127.36	85.05	9.89	4.56

[1] Labor incomes were set equal to zero if less than zero. For the semilog regressions, zero labor incomes were incremented by one dollar so that Ln earnings was defined as equal to zero.

* All F-ratios significant beyond the 0.001 level.

these employment issues as questions of "labor supply," such a view is deficient because it ignores organizational features of industrial capitalism which determine and shape the demand for labor.

In later work, we made a concession to the labor supply critics by adjusting annual earnings proportionally for the amount of labor force participation.[8] Following that convention, we adjusted the earnings in our CPS sample to eliminate differences in labor force participation, yet as the F-ratios reported in Table 1 demonstrate, regardless of whether earnings are adjusted or left unadjusted, there are significant sectoral interactions.[9] This is evidence that the sectoral effects are not reflections of simple differences in labor supply.

Choice of functional form. Hauser criticizes our use of a semilogarithmic earnings function arguing that, although there are good reasons for employing such a function, our analysis is flawed by failure to endorse his preferred justification. While Hauser chooses a statistical justification for selecting the semilogarithmic function, we prefer a justification resting on conceptual grounds.[10] Industrial segmentation theory highlights the critical role of the organization of production in shaping the demand for labor and the effects which these demand factors have on individual labor market outcomes. Becker (1964:53) argues that relative differences in earnings are more important where labor demand is the orientation while absolute differences in dollar earnings are appropriate for studies of labor supply.[11] Given the demand orientation of segmentation theory, our use of a semilogarithmic function is conceptually appropriate. Further, Mincer (1974:18) suggests that studies of income inequality should concentrate on relative differences among workers rather than worker differences in absolute dollars. This argument can be based on the declining marginal utility of labor income. If the marginal utility of income diminishes as income increases, then income transfers are relatively more important among low income workers than among work-

---

(1970), Killingsworth (1968), Levine (1972), Tsuchigane and Dodge (1974), and Sullivan (1978) as well as various papers in Gordon (1965), Wallace and LaMond (1977), and Wiesbrod (1965). See also Robert Solow's Presidential address to the American Economic Association (Solow, 1980).

[8] The adjustment involves estimating the mean earnings per week in the labor force during 1975, then multiplying the result by 52 (see Beck et al., 1980). Even this adjustment is not totally satisfactory, however, since it ignores problems of the "discouraged" worker and other forms of hidden underemployment (see Rees, 1979:10–14).

[9] All F-ratios are significant beyond the 0.001 level and were computed on the basis of the number of unweighted cases. It should be noted that the Chow tests reported in Tables 1 and 2 reflect sectoral differences in intercepts as well as sectoral differences in slopes. In a private communication, Hauser has argued that the F-ratios should be constructed to contain only slope differences. We believe this is incorrect and would lead to misleading and inconclusive results. Given the limited range of variables for such earnings models in national data sets, it is imperative to include intercept differences as measures of the sectoral affects of variables not included in the model. If variables not explicitly included in the equation have significantly different sectoral effects, their collective effects will be reflected in sectoral differences in the intercepts. Thus intercept differences as well as slope differences reflect heterogeneity in earnings determination between industrial sectors, and it would be inappropriate to exclude the intercepts from F-ratios. We note, however, that of the 32 contrasts presented in Tables 1 and 2, in only 7 instances, all involving nonwhites, were there no significant differences between slopes at the 0.05 level.

[10] Since there is ample conceptual justification for our specification, Hauser's invocation of the principle of parsimony, with its implicit ceteris paribus clause, is inappropriate and misdirected.

[11] Becker's point was cited by Featherman and Hauser (1978:288).

ers of high income.[12] From this social welfare perspective, therefore, we are guided to consider the effects of social forces on the relative differences among workers rather than absolute differences.[13] It follows that the appropriate dependent variable be log earnings, not dollar earnings.

Hauser notes correctly that the choice of an earnings function will affect the empirical findings from analyses of the earnings determination process. Specifically, sectoral homogeneity of effects in an analysis of log earnings does require sectoral heterogeneity of dollar earnings, and vice versa. However, heterogeneity in one does not imply homogeneity in the other. For reasons outlined above we chose to focus on heterogeneity in rates of return although the literature on industrial segmentation is not sufficiently well developed to specify unambiguously whether heterogeneity should be expected in dollar returns, in rates of returns, or in both.[14]

In the CPS regressions we estimated both the dollar returns and the rates of return by industrial sector and as the F-ratios in Table 1 show, there are significant sectoral interactions in both.[15] These results reinforce the basic market heterogeneity tenet of industrial segmentation theory.

Race and gender interaction. Hauser further suggests that our failure to include race and gender interactions is "curious" and may be responsible for our findings of sectoral differences in earnings determination processes. We find these assertions curious on a number of counts. (1) Hauser must be aware that the small size of the GSS data set would not support inclusion of race and sex interactions. (2) Hauser ignores our analysis in that same article which demonstrates the existence of sector differences in earnings determination among white males. (3) Hauser likewise ignores our later analysis where we addressed directly the issue of sectoral differences in earnings processes by race and gender (Beck et al., 1980).[16]

Although this issue is explored in more detail in this later paper, in the present analysis we estimated the human capital function separately by race and gender using the CPS data. The race- and gender-specific F-ratios presented in Table 1 demonstrate that there are significant sectoral interactions within each group. Thus the sectoral interactions cannot be dismissed as being an artifact of excluding race and gender interactions.

Truncating labor income. Hauser suggests that we should not have included zero earners in the earnings equation, and that their inclusion produces biased results. However, we argue that it is his exclusion of low earners which is the major source of bias. The actual distribution of labor income in the population not only contains zero earners but also a non-negligible negative tail. Many surveys, such as the GSS, ignore this negative tail and lump negative earners and zero earners into the lowest income category thus producing a censored sample distribution of labor income. Hauser's procedure of deleting zero earners (and presumably negative earners as well) is particularly ill-advised because it further distorts an already censored sample distribution by truncating its lower tail, further attentuating its dispersion and biasing upward its central tendency.[17]

---

[12] Hauser errs in suggesting that the log transformation gives undue weight to low income workers. How much weight to be given observations of differing income is a normative question which assumes some underlying specification of a social welfare function. See Allison (1978), Atkinson (1970), and Sen (1973) for discussion of this point.

[13] For a somewhat different conceptual development, see Rainwater (1974) and Coleman et al. (1978).

[14] In most of our work we have concentrated on sectoral interactions in rates of return (Beck et al., 1978; Horan et al., 1980). In Tolbert et al. (1980) a model for sectoral interactions in dollar returns was presented for purposes of a simple illustration of sectoral measurement. This does not represent the intellectual inconsistency Hauser implies.

[15] It could be argued, however, that these effects are due to the limited nature of the human capital function. In work not presented here we utilized a much more complex function (very similar to that employed by Featherman and Hauser [1978:293]) and the OCGII data to test for sectoral interactions. This analysis demonstrates that there are significant sectoral interactions in both dollar returns and rates of return even with this more complex specification. See Horan et al. (1980) for a report on a subset of these additional analyses using the OCGII data.

[16] Hauser was provided a copy of this paper at his request.

[17] If the point of interest is estimating dollar returns, and if the data have not been censored by permitting only positive values of earnings, then no particular problem exists. If, however, interest centers on estimating the rates of return an immediate difficulty is encountered: the natural log of income is undefined for zero and negative earners. There are three possible solutions to this dilemma: (1) follow Hauser's advice and truncate the distribution by deleting the offending observations; (2) censor the distribution by assigning negative and zero earners the value of one dollar so that the log of earnings is zero; or (3) recast the issue in terms of a three parameter Lognormal distribution where the displacement parameter is equal to the largest negative income (Aitchison and Brown, 1969:14–16). The first alternative has only methodological simplicity to recommend it, the second strategy is the one we have followed in past research, and the third tactic is one we are currently exploring.

Table 2. F-Tests for Segmented Market Model: Truncated Earnings[1]

	White		Nonwhite	
Labor Income	Males	Females	Males	Females
Unadjusted for Labor Force Participation				
Dollar Earnings	152.31*	96.55	22.80	16.71
Ln Earnings	170.33	145.66	19.68	16.53
Adjusted for Labor Force Participation				
Dollar Earnings	121.27	59.19	15.87	14.14
Ln Earnings	216.74	173.23	24.55	15.52

[1] Regressions computed only for workers with adjusted or unadjusted earnings greater than $1,000.
* All F-ratios significant beyond the 0.001 level.

It is interesting to note that several years ago Glen Cain (1976) argued that much of the segmentation research was methodologically questionable because empirical observations were selected on the basis of dependent variable:

> However, these tests [of market segmentation] almost invariably suffer from a methodological flaw—that of fitting the regression to a sample that is truncated on the values of the dependent variable—with the result that the estimated coefficients (effects) of the independent variable are biased. (Cain, 1976:1246)

Cain's criticism would seem to apply as well to Hauser's exclusion of low earners. Moreover, we are not inclined to adopt Hauser's unique view that lower tail of the distribution of labor income constitutes an anomaly in the stratification system of industrial capitalism. It is the exclusion of the lower tail of the income distribution which constitutes bias, not its inclusion.

Turning to the empirical question, Hauser argues that sectoral interactions are due to the inclusion of these zero earners and that when these "anomalies" are removed, the interactions disappear along with them. While it is contestable whether such workers constitute "anomalies," we explored Hauser's empirical hypothesis by replicating the regressions in Table 1 with the additional restriction that workers with labor incomes less than $1,001 were deleted from the analysis.[18] The results of the Chow tests for these truncated regressions are presented in Table 2. Again we find that regardless of race or gender, regardless of whether income is adjusted or unadjusted, and regardless of whether attention is directed toward dollar returns or rates of return, all F-ratios are statistically significant beyond the 0.001 level. This further demonstrates that even if it were conceptually reasonable to truncate the distribution of labor income, there are still significant sectoral interactions which cannot be attributed to the inclusion of low income earners.

Conclusions

In the most general terms our research examined the impact of placement within the industrial order on the earnings determination process. Beginning with the conventional neoclassical conception of the earnings process as an exchange of worker resources for economic rewards, we demonstrated that the distinction between oligopolistic and competitive modes of industrial organization serves to condition this exchange in a manner which is both substantively and statistically significant. Contrary to Hauser's assertion that there is "no substantial theoretical rationale" for such an inquiry, both our research design and empirical findings are subject to straightforward theoretical derivation and interpretation from the industrial segmentation literature in general and from the dual economy perspective in particular. Briefly, that interpretation holds that differential location of employers along the oligopoly/competitive dimension of industrial organization leads to very different strategies for the structuring of production, and the management, control, and evaluation of the workforce. (See Edwards, 1979 for a clear explanation of these issues.) One consequence of this differential organization of production is a pattern of worker experiences which varies according to placement within the industrial order. And this is precisely what the empirical research reported here and elsewhere has demonstrated: there are theoretically interpretable relationships between divisions within the industrial economy and individual labor market outcomes.

Using data unfettered by the limitations of the GSS, we have shown that the market het-

---

[18] We truncated the distribution at $1,000 for two reasons: (1) it provides a stringent test of the sectoral hypothesis, and (2) it is consistent with the procedure Hauser has followed in past research (Featherman and Hauser, 1978).

erogeneity hypothesis of segmentation theory continues to have strong empirical support throughout the range of statistical manipulations suggested by Hauser. Regardless of controls for race and gender, of whether or not income is adjusted for labor force participation, of whether effects are estimated in dollar returns or rates of return, and of whether low earners are included or excluded, basic sectoral differences in earnings processes remain. Yet we have absolutely no doubt that if one is sufficiently diligent, it would be possible to redefine the population, or the problem for that matter, so as to eliminate sectoral interactions in the earnings determination process. In the absence of an explicit theoretical model, such findings would be neither surprising nor even particularly interesting, except perhaps as a methodological footnote.

We do not suggest that our work on organizational constraints on earnings determination provides a totally adequate and complete explanation of the findings we have reported nor does it represent the only viable specification of the organizational structure of industrial capitalism. Our findings of sectoral differences in earnings represent not so much a complete explanation of underlying processes, as an identification of basic empirical regularities which need to be elaborated through further systematic inquiry. Industrial segmentation theory is but one of several structuralist perspectives which could be applied here. Wright (1979), for example, used a similar research approach to demonstrate the importance of class categories in mediating earnings determination processes.

In sum, it is our view that problems such as underemployment, poverty wages, job instability, race and gender inequalities, and regional or subregional disparities in wealth do not represent mere anomalies or market imperfections in an otherwise orderly system, but, rather, reflect an integral component of the economy of industrial capitalism. Any satisfactory paradigm for stratification research must be sufficiently robust so as to account for these features without dismissing them as anomalies and outliers. In this sense, stratification research, focusing on the positions of individuals within the social and economic organization of production, provides important advantages over the neoclassical research traditions of status attainment and human capital.

COMMENT ON NEWPORT ARTICLE*

(*ASR*, AUGUST, 1979)

I would like to make a comment, in the form of three questions, on the Newport article in the August, 1979, issue of the *American Sociological Review*.

I will not dispute Newport's findings. I have published an analysis of the same data elsewhere (Greeley, 1979: *Crisis in the Church*, Chicago: Thomas More Press). The interested reader can compare my conclusions with Newport's if he/she so desires.

(1) Why did Newport limit himself to the 1975–1976 General Social Survey data? The same questions were asked from 1973 to 1978 with a massive N of almost 9,000 cases. Why did not Newport use this larger data set since it would have enabled him to look much more closely at subpopulations—young people, for example, or Irish Catholics, a nonswitching ethnic group?

(2) Why did Newport ignore the moral, doctrinal, devotional, and religious organizational questions which are in the General Social Survey and which might explain religious switching? Thus, might not one switch from affiliation to no affiliation because, for example, one does not believe in life after death? Or might not one switch to the religion of one's spouse (as Newport concedes) because the spouse is more devout than even the typical member of such a spouse's denomination?

(3) Why does Newport pay no attention to the research done on religious change in the last two decades by scholars affiliated with NORC; scholars whose work led to the inclusion of the very questions he analyzed in the National Opinion Research Center (NORC) General Social Survey? The books by Caplowitz (1977, *The Religious Dropout: Apostacy Among College Graduates*, Beverly Hills: Sage); Kotre (1971, *View From the Border: A Social-Psychological Study of Current Catholicism*, Chicago: Aldine); and Greeley (1963, *Religion and Career*, Sheed and Ward: New York); and papers by Zelan (1968, "Religious Apostacy, Higher Education, and Occupational Choice," *Sociology of Education* 41:370–9, No. 4, Fall); and Greeley (1968, "Religious Changers," in Martin Marty, Andrew M. Greeley, and Stuart Rosenberg (eds.), *What We Believe*, New York: Meredith Press) are a fairly substantial body of literature. Either they are terrible and ought to be refuted or they are a contribution and ought to be acknowledged.

Andrew M. Greeley
National Opinion Research Center

"REPLY TO 'COMMENT ON NEWPORT ARTICLE, *ASR*, AUGUST, 1979' "*

I appreciate Professor Greeley's "Comment." Any one article is limited, of course. Professor Greeley is certainly correct in pointing out that there are additional data, variables, and studies in the literature—which I did not choose to use. Perhaps scholars who continue to investigate religious switching will want to take advantage of them.

ITEMS

■ PETER B. EVANS (Dependence, Inequality, and Growth in Less Developed Countries) is Associate Professor, Department of Sociology, Brown University. The petrochemical industry in Brazil is the subject of his current research. In 1979, his book, *Dependent Development: The Alliance of Multinational, State, and Local Capital in Brazil,* was published by Princeton University Press. MICHAEL TIMBERLAKE will be on leave from the Department of Sociology, Memphis State University (where he is Assistant Professor) in 1980–1981. He will participate in an NIMH-sponsored postdoctoral research training program in the Department of Social Relations at Johns Hopkins University. His current research continues examination of Third World countries' economic dependence and, also, of the effects of city size upon social problems.

■ RICHARD E. RATCLIFF (Capitalist Class Impact on Lending Behavior of Banks) is Associate Professor, Department of Sociology, Syracuse University. The topic, "Banks and Corporate Lending"; a study of patterns of geographic discrimination in mortgage lending ("mortgage redlining"); and research on determinants of business contributions supporting an electoral campaign to add an anti-labor union "right-to-work" amendment to the Missouri constitution are his present projects. Based on his "Banks and Corporate Lending" research, he has published an article (pages 107–32) in Maurice Zeitlin (ed.), *Classes, Class Conflict and the State* (Winthrop: 1980) as well as another (pages 115–38) in G. William Domhoff (ed.), *Power Structure Research* (Sage: 1980).

■ LALA CARR STEELMAN (Sibship Size and Birth-Order Effects on Intelligence) is a Ph.D. Candidate (and A.B.D.) in the Department of Sociology at Emory University. She is writing her dissertation on the confluence model and other explanations used to explain cognitive differences; she expects to complete, very soon, her work toward the Ph.D. JAMES A. MERCY is also a Ph.D. candidate at Emory, in the same department. He is currently analyzing time series data on police expenditures in Chicago, along with pursuing topics related to intelligence test performance.

■ RACHEL A. ROSENFELD (Race and Sex Differences in Career Dynamics) is Assistant Professor, on leave from McGill University, and Senior Study Director, National Opinion Research Center (NORC), Chicago. She continues research by: her study of careers and of the models for them; a study of farm women, funded by USDA; a study (with Chris Winship), funded by NSF, of youth unemployment and job mobility; as well as several other specific-area studies. Her basic area is stratification, with emphasis on educational choices and careers.

■ HAGEN KOO (Class and Income Inequality in Korea) is Associate Professor, Department of Sociology, Memphis State University. His ongoing research study is on Korean class structure and he is also involved in a comparative study of migration and urbanization patterns in Asia, being conducted at the East-West Center, Population Institute. He is also analyzing Asian immigration to the United States and the migrant-labor absorption in the United States labor market, from the world economic-system perspective. DOO-SEUNG HONG is Assistant Professor, Department of Sociology, Seoul National University, Korea. He has just finished his Ph.D. dissertation, "Social Stratification and Social Values in Contemporary Korea," in the Department of Sociology, University of Chicago. Social stratification, social mobility, and military sociology in developing societies are three areas of his research interest.

■ CHARLES M. JUDD (Structure of Attitude Systems in the General Public) is Assistant Professor, Department of Psychology and Social Relations, Harvard University. Methods of Social Research—particularly in applied settings—and Attitudes and Public Opinion are the two general subjects of his present research. He is the author (with R. G. Bridge and P. Moock) of *The Determinants of Educational Outcomes* (Cambridge: Ballinger, 1979) and (with D. A. Kenny) of *The Design and Analysis of Social Research in Applied Settings* (New York: Cambridge University Press), in press at this writing. MICHAEL A. MILBURN is Assistant Professor, Psychology Department, University of Massachusetts–Boston. His present research regards mass-media effects, public opinion, and health promotion. He has written a chapter in Selltiz et al. (eds.), *Research Methods in Social Relations.*

■ PHILIP E. CONVERSE (Rejoinder to Judd and Milburn) is Robert C. Angell Professor of Political Science and Sociology, as well as Program Director, Institute for Social Research—both at the University of Michigan. His current research concentrates on "Political Representation" and "Quality of Life." Those subjects were treated in his books, *Political Representation in France* (forthcoming, 1981) and, written with Campbell and Rodgers, *The Quality of American Life* (New York: Russell Sage, 1976).

■ DOUGLAS A. SMITH (Sex and Involvement in Deviance/Crime Literature) is a graduate student in the Department of Sociology at Indiana University. He is currently making an empirical examination of police-citizen encounters. Recently published articles which he has authored are "Sex and Theories of Deviance," Sociological Quarterly, Vol. 20, No. 2, and "The Myth of Social Class and Criminality" (co-authored by Charles R. Tittle and Wayne J. Villemez), *American Sociological Review,* October, 1978. CHRISTY A. VISHER is also a graduate student in Sociology at Indiana University. She is currently involved in an NIMH-funded research project to study the determinants of verdicts in jury-tried sexual assault cases in a large midwestern city. Specifically, the study explores the impact on their verdicts of the jurors' sex-role attitudes and of their attitudes toward rape.

■ BARRY GLASSNER (How Jews Avoid Alcohol Problems), Associate Professor of Sociology, Syracuse University, is continuing his research on ethnicity and alcohol abuse with a new project on Italian Americans. Other research in progress includes a study of sociological aspects of manic depression and a theoretical monograph on strategies for translating between theories of mental illness. He is the author of *Essential Interactionism: On the Intelligibility of Prejudice*, published this year by Routledge and Kegan Paul, and co-author (1979, with Jonathan A. Freedman) of *Clinical Sociology*, published by Longman. His co-author in this issue of *ASR* is BRUCE BERG, a doctoral student in Sociology at Syracuse University, who is interested in deviance, religion, and death and dying.

■ MICHAEL SWAFFORD (Parametric Techniques for Contingency Table Analysis) is Assistant Professor, Department of Sociology, Vanderbilt University. He is completing a book on Soviet education, based on a year's research in the USSR and on extensive interviews with recent émigrés; studying the relationship between education and jobs in the United States, and participating in the development of a large-scale survey of recent Soviet émigrés to the United States, Germany, Canada, and Israel.

■ ROBERT M. HAUSER (On Stratification in a Dual Economy, Comment on Beck et al.) is Professor in both the Department of Sociology and the Institute for Research on Poverty, the University of Wisconsin–Madison. His book, *Opportunity and Change*, written with David L. Featherman, was published in 1978. He is currently researching the determinants of young men's earnings, the validity of survey reports of social and economic variables, historic changes in the hierarchy of occupational status, sex differences in socioeconomic achievement, and siblings' similarities and differences in achievement.

■ ANDREW M. GREELEY (Comment on Newport) is Professor, Department of Sociology, University of Arizona. His research currently centers on correlates of the religious imagination and on ethnic alcohol subcultures. He has (with Philip Morgan) recently published *The Structures of Prayer*. Another recent book, *Explaining Ethnic Subcultures*, was written with William McCready and Gary Theisen.

CAMBRIDGE

Who Should Know What?
Social Science, Privacy and Ethics
J. A. Barnes

Barnes looks at changes in the conduct of social science research since the early nineteenth century, discussing the ethical and political obligations of social scientists in collecting data and publishing their findings. His incisive study reveals the precariousness of the survival of a truly democratic social science. Hardcover $17.50 Paper $4.95

Measurement in the Social Sciences
The Link Between Theory and Data
Richard A. Zeller and Edward G. Carmines

In this theoretical and methodological introduction to the measurement techniques used in social science research, Zeller and Carmines thoroughly explain the assumptions, limitations, and interpretations of these techniques as they discuss the ways in which measurement principles can be effectively applied in research. Hardcover $26.95 Paper $7.95

Comrades and Christians
Religion and Political Struggle in Communist Italy
David I. Kertzer

Drawing from his own participant-observation research conducted in a working-class quarter of Bologna, Kertzer effectively blends individual portraits, case studies, and sociopolitical analysis in his examination of the ways in which the people actually experience their divided loyalties—torn between a tradition of anticlericalism and a Church that decries Communism as incompatible with Catholicism. Hardcover $24.95 Paper $6.95

Sociological Explanation as Translation
Stephen P. Turner

Using well-known examples, Turner presents a new account of the grounds for and validation of "interpretive" sociological claims, arguing that there is a "rationality" to interpretation. He offers a view of the relationship between statistical and qualitative claims that shows their complementary character. His significant study breaks new ground in understanding the conceptual bases for "understanding" social behavior. *ASA Rose Monograph Series*

The Journal of
Applied Behavioral
Science

Bureaucracy in the Eighties

Volume 16, Number 3 of THE JOURNAL OF APPLIED BEHAVIORAL SCIENCE is comprised of original articles that examine the emerging characteristics and policies of large organizations that promise to shape the 1980s. Some contributors examine power and authority in organizations in an international context. Articles on multinational corporations, bureaucracy in Britain, Africa, Sweden, and the U.S. identify major forces that confront and shape organizations. Other contributors examine the impact upon persons and roles of power and authority within organizations. Quality of work life, the bureaucratic personality, the changing nature of supervision, prospects for OD, wage and grading policies, and employee participation are all examined. The articles will benefit readers with applied and with theoretical concerns. The Special Issue editors are William Boyd Littrell, Chair, Department of Sociology, The University of Nebraska and Gideon Sjoberg, a professor in the Department of Sociology, The University of Texas at Austin.

CONTENTS

Part I. Bureaucracy and Power in International Perspective—R. Kelly Hancock; Sandra L. Albrecht; Gwyn Harries-Jenkins; Peter Blunt; Sara McLanahan

Part II. Bureaucracy, Authority, and the Person—Barry Stein and Rosabeth Moss Kanter; Norma M. Williams, Gideon Sjoberg, and Andrée F. Sjoberg; Paul M. Roman; W. Warner Burke; Elliott Jaques

Publication date: August 1980

CHARLES C THOMAS • PUBLISHER

New! THE SEXUAL VICTIMOLOGY OF YOUTH

Edited by **LeRoy G. Schultz,** *West Virginia Univ., Morgantown. (21 Contributors)* This broad-based collection of articles is concerned with both the protection of children and the protection of children's rights. It is a paragon of realism in an area fraught with inaccuracies, generalizations and stereotypes of victims and offenders.

The legal control of the sexual abuse of children is considered first, with a short history of efforts in this area and discussions of the sexual victimization and molestation of children. Sections also are included on medical and psychological diagnosis and treatment, incest, the victim and the justice system, the child sex industry, and sexual emancipation. The last of these constitutes a critical evaluation of age-of-consent and statutory rape laws.

Although this text is the product of many contributors, the editor has deftly drawn the material together into a cohesive overview of the sexual victimology of youth. A definitive bibliography is included. *'80, 432 pp., 1 il., 6 tables, $19.75*

New! **POLICE-COMMUNITY RELATIONS: Crisis in Our Time (3rd Ed.)** *by* **Howard H. Earle,** *California State Univ., Los Angeles. Foreword by* **William M. Conroy.** This expanded and updated edition begins by reviewing general problems of police-community relations (PCR), including police image and crisis areas. The author explores organizational factors and, in a section on the sociology of PCR, he evaluates the import and impact of civil disobedience and riots. The final segment explores PCR programming, the individual officer, and the future of PCR. *'80, 304 pp., 5 il., 1 table, $16.75*

New! **SOCIAL PSYCHOLOGICAL PERSPECTIVES ON LEISURE AND RECREATION** *edited by* **Seppo E. Iso-Ahola,** *Univ. of Iowa, Iowa City. (18 Contributors) '80, 448 pp., 6 il., 10 tables, $19.75*

INVOLUNTARY TREATMENT OF THE MENTALLY ILL: The Problem of Autonomy *by* **Michael Alfred Peszke,** *Univ. of Connecticut School of Medicine, Hartford.* The author of this book objectively examines and analyzes the issue of involuntary treatment of the mentally ill. He suggests program designs and proposes a system in which no one is deprived of appropriate treatment while no one is deprived of personal freedom in an arbitrary manner. *'75, 176 pp., 1 il., $13.75*

New! **BURGLARY AND THEFT** *by* **John M. Macdonald,** *Univ. of Colorado School of Medicine, Denver. Contributions by* **C. Donald Brannan** *and* **Robert E. Nicoletti.** *'80, 320 pp., $19.75*

New! **URBAN COMMUNITY CARE FOR THE DEVELOPMENTALLY DISABLED** *edited by* **Herbert J. Cohen,** *Albert Eistein College of Medicine, Bronx, New York, and* **David Kligler;** *with the assistance of* **Judith Eisler.** *(21 Contributors)* In this volume, actively involved professionals focus on issues and problems in caring for developmentally disabled persons in the urban setting. Impact of the courts and consumerism on services, available residential alternatives, family services, and specific models of care are among the areas scrutinized. *'80, 360 pp., 12 il., 13 tables, $25.50*

GAMBLING AND SOCIETY: Interdisciplinary Studies on the Subject of Gambling *edited by* **William R. Eadington,** *Univ. of Nevada, Reno. (34 Contributors)* All facets of the gambling phenomena are examined in this text. Topics covered include socioeconomic aspects, the behavior and motives of both normal and compulsive gamblers, attitudes toward risk-taking, game strategies, and legalization. *'76, 488 pp., 27 il., 40 tables, $44.00*

New! **SEX, MOTIVATION, AND THE CRIMINAL OFFENDER** *by* **Robert H. Morneau, Jr.,** *California State Univ., Los Angeles, and* **Robert R. Rockwell,** *Burns International Security Services, Inc., Oakland, California.* This authoritative volume explains the role that sex plays in the psychology of the criminal offender. Following a general definition of sexuality and a review of those factors that influence the way the sexual instinct is manifested, chapters draw a complete picture of the psychosexual underpinnings of criminality. *'80, 416 pp., 46 il., $29.75*

New! **WOMEN IN LAW ENFORCEMENT (2nd Ed.)** *by* **Peter Horne,** *St. Louis Community College at Meramec, St. Louis. Foreword by* **Lewis J. Sherman.** *'80, 288 pp., 7 il., cloth-$15.50, paper-$10.50*

PLURALISM IN EDUCATION: Conflict, Clarity and Commitment *by* **Richard Pratte,** *Ohio State Univ., Columbus.* In this series of essays, the author exposes the negative influence of pluralistic ideologies that mask outmoded educational policies and practices. *'79, 232 pp., 2 il., cloth-$15.75, paper-$9.75*

GRACIAN'S MANUAL: A Truthtelling Manual and the Art of Worldly Wisdom (2nd Ed., 6th Ptg.) *translated by* **Martin Fischer.** *'79, 324 pp. (3 1/2 x 5 1/4), $7.95*

RAPE IN PRISON *by* **Anthony M. Scacco, Jr.,** *Waterbury, Connecticut.* This book employs the author's personal experiences, unpublished criminological papers, and the testimony of inmates to present a realistic view of sexual aggression in correctional institutions. The text covers such topics as the institutional setting and its contribution to sexual aggression, the sexual acts *per se*, the victims, the internal sexual violence as a microcosm of society as a whole, and the possibilities for change. *'75, 144 pp. (5 3/8 x 8 1/2), $13.50*

New! **THE OLDER WOMAN: Lavender Rose or Gray Panther** *edited by* **Marie Marschall Fuller,** *Texas Woman's Univ., and* **Cora Ann Martin,** *North Texas State Univ., both of Denton. (41 Contributors)* The lives of older women, their unique problems and their needs are described in this anthology. A broad range of articles examines such aspects as socialization, biological facts and fallacies, social bonds, institutions, alternative lifestyles, and the future of older women in society. *'80, 368 pp., 19 tables, $16.75, paper*

New! **THE NEW POLICE TECHNOLOGY: Impact of the Computer and Automation on Police Staff and Line Performance** *by* **V. A. Leonard,** *Denton, Texas. '80, 360 pp., 48 il., 4 tables, $29.75*

New! **THE ROLE OF THE FORENSIC PSYCHOLOGIST** *edited by* **Gerald Cooke,** *Norristown State Hospital, Norristown, Pennsylvania. Foreword by* **David L. Bazelon.** *(41 Contributors) '80, 432 pp., 10 tables, $26.50*

New! **TRANSSEXUALITY IN THE MALE: The Spectrum of Gender Dysphoria** *by* **Erwin K. Koranyi,** *Univ. of Ottawa, Ottawa, Ontario, Canada. Foreword by* **Ralph Slovenko.** *(3 Contributors) '80, 192 pp., 31 il., 1 table, $17.50*

OUR CHILDREN SHOULD BE WORKING *by* **William N. Stephens,** *Dalhousie Univ., Halifax, Nova Scotia, Canada. '79, 228 pp., 2 il., 1 table, $12.75*

ACUTE GRIEF AND THE FUNERAL *edited by* **Vanderlyn R. Pine, Austin H. Kutscher, David Peretz, Robert C. Slater, Robert DeBellis, Robert J. Volk** *and* **Daniel J. Cherico.** *(47 Contributors)* The articles in this book describe the psychological and social aspects of bereavement during the period of acute grief. *'76, 328 pp., 1 il., 26 tables, $21.00*

In Quest

Journal of an Unquiet Pilgrimage

SIGMUND DIAMOND. As he relates impressions of his journey—from London, through Eastern Europe and the Soviet Union, culminating in a year's stay in Israel—historian-sociologist Sigmund Diamond reveals a personal consciousness of history at work on the experience that was his own and on the experience he shared with others—Jews and non-Jews—in this turbulent century. 240 pages, illus., $10.95

Man in the Age of Technology

ARNOLD GEHLEN. Translated by Patricia Lipscomb; with a Foreword by Peter L. Berger. Probing the crisis of human personality in our century, *Man in the Age of Technology* traces the dizzying social after-effects resulting from the loss of the institutions that grew out of and sustained an earlier, agrarian age. Published in Germany in 1949, this is the first English translation of Arnold Gehlen's seminal work. $15.00

The Age of Structuralism

Lévi-Strauss to Foucault

EDITH KURZWELL. This lucid study of the sociological, political, and philosophic currents of structuralism offers introductions to eight prominent French thinkers—five who fueled the movement and three who provided intellectual opposition. Examining the work of Claude Lévi-Strauss, Louis Althusser, Roland Barthes, Jacques Lacan, Michel Foucault, Henri Lefèbvre, Alain Touraine, and Paul Ricoeur, *The Age of Structuralism* provides a lively and clear portrait of a movement whose impact still reverberates today. $20.00 cloth, $6.95 paper

Behind Every Successful Man

Wives of Medicine and Academe

MARTHA R. FOWLKES. The interconnectedness of the worlds of family and work, and the discovery that marriages are made in the image of the occupational world provide the focus for Martha R. Fowlkes' *Behind Every Successful Man*. Based on 40 in-depth interviews with the wives of physicians and university professors, the book links specific features of a wife's role to her husband's career structure and emphasizes how a wife enables her husband to work. 240 pages, $17.50

Now in paperback:

Socialism, Politics, and Equality

Hierarchy and Change in Eastern Europe and the USSR

WALTER D. CONNOR. "Connor's discussion of social structure and social change in Eastern Europe is a comprehensive and magisterial treatment of a difficult subject."—*Library Journal* 488 pages, $10.00 paper

Chinese Family and Kinship

HUGH D. R. BAKER. This work is the first synthesis in more than 30 years of what is known about traditional Chinese family and kinship relations. 272 pages, $6.00 paper

From Ritual to Record

The Nature of Modern Sports

ALLEN GUTTMANN. "A pioneering work in a field remarkably little touched, except by specialists writing about their own particular sport. For any future writer about the philosophy or the sociology of sport in general, this book will be required reading."—*Times Literary Supplement*

Machine Politics in Transition

Party and Community in Chicago

Thomas M. Guterbock

For three years, Thomas M. Guterbock participated in the daily activities of the Regular Democratic Organization in one North Side Chicago ward in order to discover how political machines win the support of the urban electorate.

Cloth 352 pages $20.00

Before the Convention

A Theory of Presidential Nomination Campaigns

John A. Aldrich

Aldrich seeks to determine why and how candidates choose to run, why some succeed and others fail, and to determine what consequences the nomination process has for the general election and, later, for the President in office.

Paper 312 pages $7.95 Also available in cloth.

The Gray Lobby

Henry J. Pratt

"*The Gray Lobby* is a success because it goes beyond the sphere of old age and provides an excellent model, based on the senior citizen movement, to explain the mass character of social movements in general, as well as policy systems and strategies for successful advocation and implementation of legislation."—Hedy Weinberg, *Social Service Review*

Paper 264 pages $5.95

The Black Extended Family

Elmer P. Martin and Joanne Mitchell Martin

The Martins point out that what appear to be fatherless, broken homes in our cities may really be vital parts of strong and flexible extended families based hundreds of miles away—usually in rural areas.

Paper 144 pages Illus. $3.95

The Joyful Community

An Account of the Bruderhof—A Communal Movement Now in Its Third Generation

With a new Preface

Benjamin Zablocki

"Ben Zablocki's book belongs on the shelves and reading lists of every social scientist concerned with communities and 'community.' "—Herbert J. Gans, Columbia University

ROUTLEDGE & KEGAN PAUL

9 Park Street, Boston, Mass. 02108

Elitism

G. LOWELL FIELD and
JOHN HIGLEY
University of Connecticut and
Australian National University

This book presents an important critique of prevailing political doctrine in Western societies at a time of major change in the circumstances of Western civilization. It pleads for a more realistic appraisal of elite and mass roles in politics, arguing that political stability and any meaningful degree of representative democracy depend fundamentally on the existence of specific kinds of elites. The authors analyse where and how Western political thought became unrealistic, and show how a restated version of elitist ideas greatly clarifies the policy and moral implication of present world conflicts. $18.50

Contemporary Hermeneutics

Hermeneutics as Method, Philosophy and Critique
JOSEF BLEICHER
Glasgow College of Technology

Contemporary Hermeneutics reveals the profound impact this philosophy is having on a wide range of intellectual pursuits, and analyses selections from the works of five major writers in the field–Betti, Gadamer, Ricoeur, Apel and Hebermas–which present the main debates going on within this new and challenging field. August $28.00, paper $14.00

Talcott Parsons and the Conceptual Dilemma

HANS P.M. ADRIAANSENS
University of Tilburg, Netherlands

This analysis of the nature and development of Talcott Parsons' theory of action offers an introduction to the conceptual paradigm upon which this theory is based, and gives an explanation of the developments which the action theory has undergone during the half-century of Parsons' career. *International Library of Sociology* August $27.50

Rousseau and Weber

A Study in the Theory of Legitimacy
J.G. MERQUIOR
Until recently, King's College, London

Rousseau and Weber are central figures in the discussion of political legitimacy; this book describes and assesses their contribution to the understanding of the subject. Dr Merquior asserts the adequacy of Rousseau's ideal of participatory democracy to the modern experience of democracy, and shows that Weber's theory of legitimacy is handicapped by the culturalism of its major premises. *International Library of Sociology* August $37.50

Edited by GEOFF MUNGHAM and
ZENON BANKOWSKI
University College, Cardiff and
University of Edinburgh
Contributors: P. Fennel, C. May, H. Williamson, R. Pearson, P. Young, M. Stephens, R. Ellis, D. Dixon, T. Keenoy, G. Mungham, Z. Bankowski

Covering a wide range of empirical and theoretical material, these essays provide an important introduction to some of the contemporary work being done by those who represent the 'newest generation' in the field. Some areas covered are plea bargaining, the role of the lawyer in juvenile courts, and lay participation in the legal process. September Original paperback about $17.50

Founding Theory of American Sociology 1881-1915

ROSCOE C. HINKLE
Ohio State University, Columbus

Professor Hinkle shows that early American sociological theory focused on social ontological interests, and by contrasting earlier and later theories, he provides a basis for interpreting one period in American theory in relation to other periods.

The price of this book was previously erroneously announced at $135.00

STATE OF KUWAIT
KUWAIT UNIVERSITY

Applications are invited for Academic Posts in Faculty of Arts & Education, Kuwait University in the following departments:

Department of Sociology & Social Work: (Prof., Assoc. Prof., Assist. Prof.)

1. Anthropology: General Anthropology

2. Sociology: Methodology, Statistics, Social Psychology, Social Organization, Sociological Theories

3. Social Work: Social Welfare Policy, Social Work Practice, Human Behaviour & Social Environment, Field Instruction

4. Department of Psychology: (Assist. Prof.) Organizational Psychology

For all of the above positions:

Contracts for two years, renewable for a further period of four eyars by mutual agreement of the two parties, in accordance with the following:

Teaching Arabic is a must.
Method of teaching is based on the credit system.
Holding of Ph.D. degree or its official equivalent.
Applications which will not be considered are:

☐ Non holders of Ph.D. degrees or its equivalent, even if they are expected to hold it later on.
☐ Applications submitted for other specializations.

Early applications will be given priority.

Completed applications including full details together with a non-returnable copy of the Ph.D. degree, other academic qualifications, and candidate's publications, should be sent directly to Department of Administrative Affairs, P. O. Box 5969 (Safat) Kuwait.

Additional information required by the candidate can be requested on the course in subject, from:

Chairman, Dept. of Sociology & Social Work
or
Chairman, Dept. of Psychology
Faculty of Arts & Education
Kuwait University
P. O. Box 23558
(Safat)
Kuwait

Notice to Contributors

A processing fee of $10 is required for each paper submitted, except for comments; such fees will be waived for student members of ASA. A check or money order, made payable to the American Sociological Association, should accompany each submission. The fee must be paid in order for the review process to begin.

The length of an *ASR* paper is generally ten (10) printed pages or thirty (30) typed pages. However, the *ASR* is happy to accept manuscripts up to fifty (50) typed pages in length for review. We also are interested in receiving manuscripts for a Research and Notes Section.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose only compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, *the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.*

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using *"ibid.," "op. cit.," or "loc. cit."* Examples follow:

1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971. Cohen, 1962) . . ."]

B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)

If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."

Use no underlining, italics or abbreviations.

Examples follow:

1. *Books:*	Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch	
	1970	Ex-Pastors. Philadelphia: Pilgrim Press.
	U.S. Bureau of the Census	
	1960	Characteristics of Population. Volume 1. Washington, D.C.: U.S. Government Printing Office.
	Bernard, Claude	
	[1865] 1957	An Introduction to the Study of Experimental Medicine. Tr. Henry Copley Greene, New York: Dover.
2. *Periodicals:*	Conger, Rand	
	Forthcoming	"The effects of positive feedback on direction and amount of verbalization in a social setting." Pacific Sociological Review.
	Merton, Robert K.	
	1963a	"The ambivalence of scientists." Bulletin of The Johns Hopkins Hospital 112:77–97.
	1963b	"Resistance to the systematic study of multiple discoveries in science." European Journal of Sociology 4:237–82.
3. *Collections:*	Davie, M.	
	1938	"The pattern of urban growth." Pp. 133–61 in G. Murdock (ed.), Studies in the Science of Society. New Haven: Yale University Press.

See recent issues for further examples.

Copy Editor: ELIZABETH ROBINSON NEUMANN

Managing Editor: SHARON GUNASON

Editorial Assistant: HELEN CURLEY

Executive Officer: RUSSELL R. DYNES

SCOPE AND MISSION OF AMERICAN SOCIOLOGICAL REVIEW: The *American Sociological Review* publishes work of interest to the discipline in general, new theoretical developments, results of research that advance our understanding of the most fundamental social processes, and important methodological innovations. Like other publications of the Association, emphasis is given to exceptional quality. Unlike the more specialized journals of the Association, the *American Sociological Review's* primary focus is on whatever has the most general bearing on the knowledge of society.

Concerning manuscripts, address: Editor, *American Sociological Review*, Department of Sociology, University of Illinois, Urbana, Illinois 61801. (217) 333-6515.

The *American Sociological Review* (ISSN 0003–1224) is published at 49 Sheridan Avenue Albany, New York, bimonthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office

Copyright © 1980 American Sociological Association:

Annual membership dues of the American Sociological Association, $20–$120 ($10 of this amount may cover a subscription to the *American Sociological Review*); Associate, $25; International Associate, $25; Student Associate, $12.

Application for membership and payment of dues should be made to the Executive Office. Subscription rate for members, $10; nonmembers, $15; institutions and libraries, $30; nonmember students, $10. Single issue, $4.

New subscriptions and renewals will be entered on a calendar year basis only.

Change of address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

Concerning advertising, changes of address, and subscriptions, address: Executive Office, American Sociological Association, 1722 N Street, N.W., Washington, D.C. 20036.

Claims for undelivered copies must be made within the month following the regular month of publication. The publishers will supply the missing copies when losses have been sustained in transit and when the reserve stock will permit.

Second class postage paid at Washington, D.C. and additional mailing offices.

AMERICAN SOCIOLOGICAL REVIEW

HEREDITY, ENVIRONMENT, AND PUBLIC POLICY RECONSIDERED*

CHRISTOPHER JENCKS
Northwestern University

American Sociological Review 1980, Vol. 45 (October):723–736

Given suitable data, we can estimate the degree to which genetic variation explains observed variation in human behavior (h^2). But, contrary to what most investigators assume, the amount of nongenetic variation ($1 - h^2$) sets no upper limit on the explanatory power of environmental variation. This is because genetic variation often causes environmental variation, so the two categories are not mutually exclusive. The assumption that the two categories are mutually exclusive derives from a narrowly physiological model of the way in which genes affect behavior. This model is inconsistent with all the most familiar examples of genes affecting behavior, especially the examples of race and sex. Heritability estimates set no upper limit on the potential effect of reducing or eliminating variation in environmental factors that currently vary in response to genotype, as many do. Nor do they set an upper limit on the effect of creating new environments. Heritability estimates *do* set an upper limit on the effect of reducing or eliminating environmental variations that are independent of genotype, but other statistics usually provide even better estimates of these effects. There is no evidence that genetically based inequalities are harder to eliminate than other inequalities. Until we know *how* genes affect specific forms of behavior, heritability estimates will tell us almost nothing of importance.

INTRODUCTION

Both social and natural scientists have been quarreling about the relative importance of heredity and environment for more than half a century. So far as I can discover, this seemingly endless debate has not led to a single substantive insight into the causes of specific forms of human behavior. When debates prove persistently unfruitful, one must at least entertain the hypothesis that the participants are asking the wrong questions.

This paper is divided into four parts. Part I examines the traditional terms of the heredity-environment debate, illustrating their meaning with concrete examples. It shows that while we can, in principle, estimate the fraction of the variance in human behavior currently traceable to genetic variation, we cannot ordinarily estimate the fraction of the total variance attributable to environmental factors. Part II argues that we can understand the effects of heredity and environment more easily if we think in terms of recursive equations than if we think in terms of a traditional analysis of variance. It shows that while we can, in principle, estimate certain parameters of the reduced-form equations that include both genotype and exogenous environmental factors, we cannot estimate the parameters of structural equations that also include endogenous environmental factors which depend partly on genotype. Part III analyzes the widespread but fallacious assumption that genetic explanations of human variation are likely to be exclusively physical explanations while environmental explanations are likely to be social, illustrating the argument with a discussion of racial and sexual differences. Part IV discusses the kinds of policy implications that can be drawn

I am indebted to Miriam Flacks, Arthur Goldberger, Robert Hamblin, John Loehlin, and Sandra Scarr for helpful criticisms of earlier versions of this paper, one of which was presented at the August, 1979, meeting of the American Sociological Association.

from heritability estimates, arguing that they are very limited.

I. *The Traditional Approach*

The traditional approach to the "heredity-environment" question uses language in a way that is easily misunderstood. If we want to understand what this approach can and cannot tell us, an example is helpful.

Suppose that a farmer alternates two genetically pure strains of corn in the same field over many years, that Strain A's average yield is 1,120 bushels, that Strain B's average yield is 880 bushels, and that the standard deviation of the annual yields over the entire period is 200 bushels. Population geneticists usually describe such findings using the following terms:

(1) Each strain's expected yield under this range of environmental conditions is called its *genotypic value* (or simply its *genotype*). In the absence of a change in environmental conditions, each strain's expected yield is simply the mean of past yields. The genotypic values are thus 1,120 bushels for Strain A and 880 bushels for Strain B.

(2) The variance of the genotypic values under this range of environmental conditions is called the *genetic variance*. Since Strains A and B have equal frequencies in this example, the genetic variance is $(1{,}120-1{,}000)^2 (0.50) + (880-1{,}000)^2 (0.50) = 14{,}400 = 120^2$.

(3) The observed yield in a given year is the *phenotypic value* (or simply the *phenotype*).

(4) The observed variance of the annual yields is the *phenotypic variance*. In this instance the phenotypic variance is $200^2 = 40{,}000$.

(5) The ratio of the genetic variance to the phenotypic variance is the *broad heritability* (or simply the *heritability*, usually denoted as h^2). In this instance $h^2 = 14{,}400/40{,}000 = 0.36$. Note that we can also think of heritability as the ratio of the between-strains variance to the total variance.

(6) The variance not attributable to genetic variation—that is, the within-strains variance—is usually called the *environmental variance*. In this case the environmental variance is supposed to be $40{,}000 - 14{,}400 = 25{,}600 = 160^2$. Using this definition, the ratio of the environmental variance to the total variance is necessarily equal to $1 - h^2$—that is, 0.64.

The first five definitions pose no serious problems. The sixth is seriously misleading, as it uses the term "environment" in a way quite different from the way in which social scientists and lay persons use it.

Suppose, for example, that the yield in our hypothetical field depends entirely on the number of grasshoppers attacking the crop and that Strain A yields more than Strain B solely because Strain A is less attractive to grasshoppers. Since most of us think of grasshoppers as part of the environment, most of us would describe this situation by saying that environmental variation explained 100% of the variance in yield. But because the environment depends partly on what strain has been planted, we would also say that genetic variation explained 36% of the environmental variation. The conventional language of population genetics, in contrast, asserts that environmental variation explains only 64% of the variance in yield. Some grasshoppers are thus "environmental"; others, "genetic."

Thus, what population geneticists and their followers call "environmental variance" is only that part of the total environmental variance not traceable to genetic variation. In technical terms, this is the "exogenous" environmental variance.

The theoretical problems we encounter when we study people are much the same as those which appear when we study corn. Among people, of course, we have no genetically "pure" strains—that is, no large groups of individuals who all have exactly the same genes. We do have pairs of identical twins, however; so in principle we can conduct experiments rather like the one just described with corn.

Suppose, for example, that we were to identify pairs of identical twins, separate them at birth, and assign them to random homes. Any correlation between such twins' phenotypic values on traits such as height, IQ, mental health, or income would have to be due either to their common genes or to their common prenatal environment. There is little evidence that variation in prenatal environment explains a significant fraction of the variation in any of these phenotypes. If prenatal environments are not important, the correlation between separated twins is, as we shall see in Part II, equal to the ratio of the genetic variance to the total phenotypic variance—that is, h^2.

In practice, of course, separated identical twins are never assigned to new homes on a random basis. But our concern at this point is not with practical problems of estimation, to which I return below, but with what inferences we could draw assuming we had "ideal" data. Suppose, for example, that some adoption agency *had* separated large numbers of identical twins and assigned them to random homes. And suppose that, after correcting for measurement error, we found a correlation of 0.40 between separated pairs' reading scores at the age of ten. What could we infer?

First, we could infer that genetic variation accounted for roughly 40% of the variation in ten-year-olds' reading scores.

Second, we could infer that environmental factors plus interactions between environmental factors and genes accounted for at least 60% of the variation in ten-year-olds' reading scores.

But we could not rule out the possibility that the environment accounted for *more* than 60% of the total variance in reading scores. Nor could we infer that equalizing children's environments would reduce variation in reading scores by only 60%. If children's genes affect their environment, separated identical twins' overall environments could be positively correlated even though the exogenous features of their environments were uncorrelated. Environment as a whole could then account for more than 60% of the variation in reading scores, even though genes accounted for 40%. In the extreme case, equalizing children's environments might eliminate *all* the variance in reading scores, not just 60%.

An individual's genes can influence his or her environment in at least two distinct ways.[1] First, genes can affect the way in which the environment reacts to the individual. Every society treats males differently from females, for example. Every society also treats those who conform to its standards of beauty differently from those who do not. Such variation in the way society treats individuals with different genes can obviously lead to variation in individual behavior, affecting traits as diverse as reading scores, mental health, and income.

Second, even when the environment is blind to a given set of genes, these genes can affect the environment individuals choose for themselves. Those with unusually light skin, for example, tend to burn more easily when exposed to the sun. Not surprisingly, they tend to avoid the sun, accentuating genetic differences in skin color. Likewise, genes seem to affect the ease with which people read, and those who read easily also read more than those who read with difficulty. This not only accentuates initial differences in reading comprehension, but leads to differences in vocabulary, general information, attitudes, and values.

Once stated, the idea that our genes affect our environment is so obvious as hardly to require demonstration. The real puzzle is why neither population geneticists nor social scientists concerned with genetic influences have taken seriously the implications of this obvious fact. The answer seems to be that these investigators have been almost exclusively concerned with ascertaining the importance of genetic variation and, for this purpose, as Roberts (1967:218) has argued, "it matters not one whit whether the effects of the genes are mediated through the external environment or directly through, say, the ribosomes." But if one is interested in the effects of *environmental* variation, it is absolutely crucial to distinguish the effects of genes "mediated through the external environment" from those mediated "through, say, the ribosomes."

---

[1] The following analysis is analogous in certain respects to that of Plomin et al. (1977), although the conclusions are very different. Plomin et al. distinguish three sources of correlation between genotype and environment: passive, reactive, and active. A "passive" correlation arises when a parent's genes affect both a child's genes and its environment. In principle, one can estimate the magnitude of this effect empirically (Jencks et al., 1972; Loehlin, 1978). The present paper is not concerned with this problem, which involves a correlation between genotype and what I here call "exogenous" environment. What Plomin et al. label a "reactive" correlation between genotype and environment arises when the environment responds differently to individuals with different genes. What they label an "active" correlation arises when individuals with different genes seek out or create different environments. This paper is concerned with "reactive" and "active" sources of correlation between genotype and environment.

Several social scientists have recognized this problem (e.g., Jencks et al., 1972; Jensen, 1976; Plomin et al., 1977), but none has tried to solve it. Instead, they have tried to define it away. Jencks and Brown (1977), for example, define the "environment" as including only those elements that vary independently of an organism's genes. This is equivalent to partitioning the variance attributable to environment into endogenous and exogenous components and restricting the label "environment" to the latter. This shorthand might be acceptable if we knew which specific elements of the environment varied for exogenous reasons and which varied for endogenous reasons. But few specific elements of the environment fall unambiguously into either category, as the case of the grasshoppers illustrated. *Estimating the explanatory power of the exogenous environment therefore sets neither a ceiling nor a floor on the explanatory power of specific features of the environment.*

The conventional, generally understood meaning of the term "environment" is extremely broad. That is precisely why both social and natural scientists find it useful. Narrowing the definition (while retaining the term itself) is certain to mislead all but the most attentive and sophisticated readers. Indeed, it is only a slight exaggeration to say that narrowing the definition of a term that has traditionally had a very broad meaning is *meant* to mislead—that is, it is meant to make one's results sound more significant than they really are. If an investigator wants a simple, descriptive label for those influences that are independent of genotype, the term "nongenetic" is ready at hand. Equating these unexplained residual influences with "environment" can only generate confusion and misunderstanding.

II. A Recursive Model

The verbal argument of the previous section suggests that we need two recursive equations to describe the relationships among heredity, environment, and phenotype. Phenotype (P) depends on Genotype (G^*) and Environment (E). Since the metrics of G^* and E are arbitrary, let us scale them so that their coefficients in an equation predicting P are both 1.00. Our first structural equation is then:

$$P = G^* + E + u_P \tag{1}$$

where u_P is an error term uncorrelated with G^* and E, attributable partly to interactions between the elements of G^* and E and partly to random errors in measuring P. Environment depends on both genotype and other factors that we label "exogenous environment" (X). Since the genetic factors that influence the environment need not be identical to those that influence the phenotype with environment controlled, we need a second genetic variable, G^{**}, to denote these genetic factors.

Our second equation is then:

$$E = G^{**} + X + u_E \tag{2}$$

where u_E embodies interactions between the components of G^{**} and X.[2]

Substituting from Equation 2 into Equation 1 we obtain the reduced form estimate of P:

$$P = G^* + G^{**} + X + u \tag{3}$$

where $u = u_P + u_E$. Setting

$$G^* + G^{**} = G \tag{4}$$

---

[2] We can test for interactions between the overall values of G and X by examining the relationship between pair means and pair differences in samples of genetically related pairs reared apart. If we find such interactions we can usually eliminate them by rescaling G and E. Interactions between *specific* genes and *specific* environments (that is, between the components of G and X) may, however, also make $s^2_{u_E} > 0$. Such interactions need not produce any systematic relationship between pair means and pair differences (Jencks and Brown, 1977).

we can rewrite Equation 3 as:

$$P = G + X + u. \qquad (5)$$

As we shall see, heritability estimates are concerned with the relationship of G and X to P. Yet we habitually discuss them as if they were estimates of the relationship of G* and E to P. The two sets of relationships are obviously quite different.

Suppose, for example, that we want to estimate the amount of phenotypic variance among individuals who have the same environment—that is, the same value of E. The exact value may vary if there are interactions between the components of G and E, but if we ignore the error variance our best estimate is Var (G*). Conventional heritability estimates assume the value is Var (G)—that is, the phenotypic variance with only the exogenous environment controlled. Yet taking the variance of both sides of Equation 4, and rearranging, shows that:

$$\mathrm{Var}(G^*) = \mathrm{Var}(G) - \mathrm{Var}(G^{**}) - 2\mathrm{Cov}(G^*G^{**}). \qquad (6)$$

We ordinarily expect $r_{G^*G^{**}}$ to be positive. Equation 6 therefore indicates that as a general rule Var(G*) is smaller than Var(G), perhaps much smaller. Conventional heritability estimates thus overestimate the phenotypic variance among individuals with identical environments.

If we want to know how much phenotypic variance there is among individuals with identical genotypes, we are in somewhat better shape. The exact value may again vary if there are interactions between the components of G and X, but if we ignore the error variance our best estimate is Var(X). As we shall see, conventional heritability estimates provide fairly plausible estimates of Var(X).

In most instances, however, we do not want to know the phenotypic variance among individuals with identical genotypes. We want to know how much we could reduce the phenotypic variance if we equalized everyone's environment. The conventional estimate is Var(P) − Var(G). The correct estimate is Var(P) − Var(G*). Since Var(G*) is ordinarily smaller than Var(G), conventional procedures usually underestimate the impact of equalizing environments.

The magnitude of the foregoing biases depends on how much genotype affects environment. Since we have no working definition of "environment" and no way of saying when two individuals have the same environment, we cannot hope to devise general procedures for estimating the bias. The most we can hope to do is assess the impact of genes on those specific features of the environment we can actually define and measure.

While it is in principle possible to estimate the overall phenotypic variance due to genes (Var(G)), data limitations mean that we must treat existing estimates with extreme caution. To see why this is so, it helps to review the conventional procedures for making such estimates. Imagine a sample of collateral relatives: identical or fraternal twins, full siblings, half siblings, or cousins. Suppose we sort these relatives into pairs and record the data on each pair twice, reversing their order. Let us denote the phenotype for the first member of each pair as P and the phenotype for the second member as P′. This makes $s^2_{P'} = s^2_P$, $s^2_G = s^2_{G'}$, $s^2_E = s^2_{E'}$, $r_{GE} = r_{G'E'}$, $r_{GE'} = r_{G'E}$, and so forth. It also means that:

$$P' = G' + X' + u' \qquad (5')$$

Now suppose we measure all phenotypes as deviations from the sample mean. If we then multiply Equation 5 by Equation 5′, sum over all pairs, divide by the number of pairs, and assume that the relatives do not influence one another, so that the correlations involving u and u' are 0, we get:

$$\mathrm{Cov}(PP') = \mathrm{Cov}(GG') + \mathrm{Cov}(XX') + 2\mathrm{Cov}(GX') \qquad (7)$$

or in slightly different notation,

$$r_{PP'}\, s^2_P = r_{GG'}\, s^2_G + r_{XX'}\, s^2_X + 2r_{GX'}\, s_G s_X \qquad (8)$$

If we collect data on genetically related individuals reared apart, and if their exogenous environments prove uncorrelated, $r_{XX'} = r_{GX'} = 0$. Rearranging then gives us:

$$\frac{s^2_G}{s^2_P} = \frac{r_{PP'}}{r_{GG'}}. \qquad (9)$$

If the separated pairs are identical (MZ) twins, $r_{GG'} = 1$ and $s_G^2/s_P^2 = r_{PP'MZA}$, where the subscript MZA represents MZ twins reared apart. If the separated pairs are fraternal (DZ) twins or ordinary siblings (S), genetic theory tells us that $r_{GG'} \sim 0.5$ and $s_G^2/s_P^2 \sim 2r_{PP'DZA} \sim 2r_{PP'SA}$.[3] If the separated pairs are half-siblings (HS), $r_{GG'} \sim 0.25$ and $s_G^2/s_P^2 \sim 4r_{PP'HSA}$.

Unfortunately, we have no data on separated collateral relatives other than identical twins and full siblings, and even these data cover only one phenotype of interest to sociologists—namely, IQ scores. Furthermore, Taylor (in press) shows that, for existing samples of separated identical twins, exogenous environments tend to be positively correlated (that is, $r_{XX'} > 0$), though one can perhaps identify subsamples in which this is not true. Internal evidence also suggests that $r_{XX'}$ exceeds zero in the only well-documented study of separated siblings (Freeman et al., 1928). Finally, the phenotypic variance for separated relatives tends to be smaller than for the general population. This could be because of restrictions on the genetic variance, the exogenous environment variance, the covariance between genotype and exogenous environment, or some combination of the three.[4] Generalizing from these samples to any larger population is therefore difficult.

Because data on separated collateral relatives is so poor, most heritability estimates rely heavily on relatives reared together. To estimate s_G^2 or s_G^2/s_P^2 from relatives reared together, we need two kinds of relatives for whom the genetic correlation ($r_{GG'}$) differs while the exogenous environmental correlation ($r_{XX'}$) is the same. For illustrative purposes let us consider identical (MZ) and fraternal (DZ) twins. Using the subscripts *M* and *D* to denote the two types of twins, we can write Equation 8 as:

$$r_{PP'M}s_{PM}^2 = r_{GG'M}s_{GM}^2 + r_{XX'M}s_{XM}^2 + 2r_{GX'M}s_{GM}s_{XM} \qquad (8M)$$

and as

$$r_{PP'D}s_{PD}^2 = r_{GG'D}s^2_{GD} + r_{XX'D}s_{XD}^2 + 2r_{GX'D}s_{GD}s_{XD}. \qquad (8D)$$

If the phenotypic variance is the same for MZ and DZ twins, we can plausibly assume that the same is true for s_G^2 and s_X^2. Subtracting Equation 8*D* from Equation 8*M* then yields:

$$(r_{PP'M} - r_{PP'D})s_P^2 = (r_{GG'M} - r_{GG'D})s_G^2 + (r_{XX'M} - r_{XX'D})s_X^2 + 2(r_{GX'M} - r_{GX'D})s_G s_X. \qquad (10)$$

If $r_{XX'M} = r_{XX'D}$ and $r_{GX'M} = r_{GX'D}$ Equation 10 reduces to a variant of Jensen's (1967) formula:

$$\frac{s_G^2}{s_P^2} = \frac{r_{GG'M} - r_{GG'D}}{r_{PP'M} - r_{PP'D}}. \qquad (11)$$

While the assumption that $r_{XX'M} = r_{XX'D}$ is intuitively implausible, the scanty available evidence supports it (Plomin et al., 1976; Lytton, 1977; Scarr and Carter-Saltzman, in press). The assumption that $r_{GX'M} = r_{GX'D}$ may also seem problematic. But since G correlates with X′ only insofar as parental genes affect both G and X′, $r_{GX'} = r_{GX}$ for twins and full siblings. The assumption that $r_{GXM} = r_{GXD}$ seems quite reasonable. Thus, while a certain amount of scepticism about twin studies is certainly warranted (Jencks and Brown, 1977; Goldberger, 1979), they may nonetheless yield satisfactory estimates of s_G^2. If so, we can estimate s_G^2 for a relatively large number of traits that interest sociologists, including not only IQ but personality traits (e.g., Loehlin and Nichols, 1976), educational attainment (Taubman, 1976; Jencks and Brown, 1977), occupational status (Taubman,

---

[3] The value of $r_{GG'}$ is exactly 0.50 if genes have additive effects and there is no assortative mating. Assortative mating raises the expected value while interactions among genes lower it.

[4] The genetic variance is restricted to the extent that genetically advantaged parents are less likely than others to have children whom they later have to give up, or that genetically disadvantaged children are more likely than others to end up in orphanages, where mortality is extremely high. The environmental variance is restricted to the extent that adoption agencies avoid placing children in unfavorable environments. The covariance is restricted insofar as adoption agencies are less successful than nature in matching children's genotypes to their adoptive parents' phenotypes. (For evidence on this last point see Jencks et al., 1972.)

1976; but see Corcoran and Jencks, 1979), and earnings (Taubman, 1976).[5]

Since twin studies depend on the assumption that $r_{XX'_M} = r_{XX'_D}$, a cautious investigator would want to check such results using other kinds of collateral relatives. The most obvious possibility is to compare full siblings reared together to adopted siblings reared together. Adopted siblings are harder to locate than twins, and data on adopted siblings are not available for anything like as wide a range of phenotypes. Indeed, IQ is virtually the only phenotype for which we have data on adopted children.[6] Furthermore, the phenotypic variance of IQ among adopted pairs is usually lower than among natural pairs. Since it is not obvious whether this is attributable to restriction of the genetic variance, of the exogenous environmental variance, or of the covariance (see footnote 4), we cannot use the same procedure for comparing natural and adopted siblings that we used for identical and fraternal twins. Indeed, without a convincing explanation for the discrepancy in phenotypic variances, comparing covariances or correlations from samples of natural and adopted siblings cannot tell us either the genetic variance or the heritability for either group.

In theory, we might do better if we compared full siblings and half siblings reared together. In order to minimize discrepancies in $r_{XX'}$, we could look exclusively at pairs in which the fathers had been absent while the children were growing up. Such data are not currently available, but they would not be hard to collect, since such sibships are quite numerous.

For a still fuller picture, we would want to utilize data not only on collateral relatives but also on parents and offspring (see, e.g., Loehlin, 1978, and the sources cited there).

Despite the many practical difficulties that arise when we try to estimate the genetic variance of human traits, such estimates are clearly feasible, *in principle*. These estimates are only feasible *in practice*, however, when we use a reduced-form model that includes only genotype and exogenous environment. Models that include the environment as a whole are hopelessly underidentified. Thus, while we can, in principle, draw conclusions about the importance of genes in explaining variation in human attributes and behavior, we cannot draw comparable conclusions about the importance of environment. This is hardly surprising. We have a reasonably clear idea of what a gene is and how genetic correlations arise among relatives. We have no clear idea what "environment" is and no theory for predicting environmental correlations among relatives or anyone else.

III. The "Genetic=Physical and Environmental=Social" Fallacy

While population geneticists have ignored the implications of genes' affecting the environment partly because they are almost exclusively concerned with demonstrating the importance of genetic variation, regardless of the mechanisms involved, most have also assumed that genes were, in fact, far more likely to operate "directly through, say, the ribosomes" than to have effects "mediated through the environment."

---

[5] While twin samples usually yield IQ variances comparable to those for the general population, this is not necessarily true for other traits. Taubman's (1976) twin sample, for example, has less variable earnings than representative samples of white men in the same age range. This could be because their genes are less variable, because their environments are less variable, or because their genes are less correlated with their environments. The relationship of s_G^2 or h^2 in Taubman's sample to s_G^2 or h^2 for other populations is thus murky.

[6] The best recent studies are by Scarr and Weinberg (1978) and Horn et al. (1979). For reviews of earlier studies see Munsinger (1975) and Kamin (1978).

[7] Of course, neither racial nor sexual identity depends exclusively on genes. Individuals with male genes can define themselves as female, and vice versa, and in some cases others accept these definitions, especially if the individuals in question have undergone sex change operations so that their anatomy conforms relatively closely to the norm for the sex with which they identify. Likewise, skin color and facial features do not completely determine an individual's racial identity. Many an individual's physical appearance does not conform clearly to any prevalent racial stereotype. In these cases, observers usually infer racial identity from contextual evidence, such as the racial identity of the parents (if known), the individual's self-reported racial identity, and other factors. These ambiguities do not, however, affect the validity of my basic argument.

Such a bias is not surprising among physical scientists. More surprising is its almost universal acceptance among social scientists. Consider the case of IQ scores. Having assembled evidence that genetic variation contributes to phenotypic variation in IQ, psychologists have hardly even bothered to ask themselves *how* this comes about. Both hereditarians and environmentalists have simply assumed that if genes do, in fact, affect IQ, they do so by affecting the development of the central nervous system—particularly the brain. No one has spelled out this view in detail, since it would have to be built entirely on conjecture. But the physical form of the model is implicit in innumerable arguments, the most obvious example being the argument that high heritabilities "explain" the failure of environmental manipulations to alter IQ scores—a point to which I will return below. Most environmentalists have accepted this model. As a result, they have felt obliged to argue that genes do not affect IQ scores—or at least not much. It does not seem to have occurred to them to concede that genes might be important and then to argue that genes could exert their influence primarily by determining a child's environment. Given the environmentalists' extraordinary ingenuity in explaining away evidence that genes are important in the first place, their failure to argue that genes may exert their impact largely through the environment is puzzling.

Environmentalists do, of course, make this argument in specific instances, without recognizing the argument's general implications. Consider the case of sex differences. The debate about sex differences in mathematical achievement, for example, is usually portrayed as a debate about whether these differences are "genetic" or "environmental" in origin. From the viewpoint of population genetics, however, such differences are genetic *by definition*. Individuals who inherit two X chromosomes (females) differ from those who inherit only one (males). For the population geneticist, it "matters not one whit" whether this is because the chromosomal difference produces internal physiological differences that affect behavior or because the chromosomal difference produces visible external differences that lead society to treat the two sexes differently. Either way, the *ultimate* cause of sex differences is genetic. The "heredity-environment" debate is only about proximate causes or, if one prefers, about the nature of the intervening variables through which sex affects behavior. What we label the "hereditarian" position is the view that these intervening variables are physical. What we label the "environmental" position is the view that they are social.

Debate about racial differences uses these same misleading labels. The "hereditarian" explanation of racial differences in IQ scores, for example, assumes that the genes which influence skin color and facial features either exert a direct effect on the central nervous system and brain or, more plausibly, that they tend to be associated with other genes that exert such effects. The "environmental" explanation assumes that skin color and facial features determine an individual's racial identity which then affects the way society treats an individual and perhaps also the way an individual treats himself or herself. Just as in the case of sex differences, both sides agree that genes have important effects on test performance. Disagreement is about proximate causes and focuses on whether these proximate causes are physical or social.[7]

Why have environmentalists never generalized their explanations of sex and race differences to other genetic determinants of human behavior? Admittedly, it is hard to think of other physical traits that affect the way society treats an individual to the extent that race and sex do. (Physical beauty probably has comparable effects in extreme cases, but few cases are extreme.) Genes need not, however, affect appearance in order to affect an individual's environment. In an industrial society, for example, a student with an aptitude for reading will typically be assigned to quite different environments from a student who has trouble reading. These environmental differences will then generate differences in a wide range of phenotypes, ranging from political attitudes to personal income.

While environmentalists have been slow to recognize the general implications of their analysis of racial and sexual differences, many hereditarians have implicitly done so. Those who estimate the heritability of human traits almost invariably separate respondents by race. Many separate respondents by sex as well. They then estimate heritabilities within racially and sexually homogeneous subpopulations. The naive observer might wonder why hereditarians do this for race and sex but not for other characteristics that depend largely on genotype—such as height, physical appearance, weight, eye color, or blood type. The obvious answer is that if an investigator were to pursue this approach to its logical conclusion, he or she would end up with a series of genetically homogeneous subsamples. Within these subsamples, phenotypic variation would by definition be nongenetic in origin, and h^2 would be zero. But why, then, have hereditarians treated race and sex as "special?" Why not treat race and sex just like other genetic sources of phenotypic variance? If we were to draw a random sample of identical twins, separate them at birth, and assign them to random families, for example, all pairs would be of the same sex, and virtually all pairs would end up being treated as if they were of the same race. If sex or race affected a given phenotype, they would contribute to resemblance between separated pairs and increase the estimated value of h^2. Why, then, have hereditarians generally preferred to estimate h^2 within racially and sexually homogeneous samples?

One possible answer is that heritabilities could vary by race and sex. But heritabilities could also vary for many other subpopulations. They could be higher in urban than in rural environments, or higher in high SES homes than in low SES homes, or vice versa. There is no theoretical reason to expect the same heritability in *any* two subgroups. Indeed, heritabilities are likely to vary from family to family, depending on whether the family allocates its resources so as to accentuate genetic differences or offset them.

A second possible reason for estimating heritabilities separately by race and sex is the implicit recognition that pooling races and sexes will make the effects of race and sex genetic as a matter of definition. Many investigators are uncomfortable with this assumption. They also assume, however, that race and sex are atypical. The argument of this paper is that they may, in fact, be quite typical. Given our almost complete ignorance of how genes affect the phenotypes that interest social scientists, the assumption that the genes determining race and sex are different from all other genes is premature, to say the least. The assumption that race and sex operate in the same way as other genes—or in the same way as each other—is equally premature. We simply do not know enough at present to draw any sensible conclusions about how most genes exert their effects.

The foregoing argument suggests that, instead of unconsciously equating genetic effects with physical effects and nongenetic effects with social effects, we should recognize that these two dimensions are independent of one another and think in terms of a two-by-two table. Table 1 presents an illustrative classification of phenomena affecting test performance.

Cell I covers what have traditionally been regarded as "genetic" explanations of test score variance—that is, explanations that not only invoke genes as an exogenous cause of variation but also emphasize endogenous physical factors in accounting for genes' effects on test performance. Phenylketonuria (PKU) is an example. PKU is a genetic disorder that prevents an individual from metabolizing phenylalanine. If an individual consumes

Table 1. Sources of Variation in Test Performance

Proximate Endogenous Cause	Exogenous Cause	
	Genetic	Nongenetic
Physical	(I) PKU	(II) Lead Poisoning
Social	(III) Sexism	(IV) Language spoken at home

a normal diet, this disorder significantly lowers his or her expected IQ. If this were the whole story, PKU would fit neatly into Cell I. But because we know how to identify PKU and how to treat it—by drastically reducing the amount of phenylalanine in an affected individual's diet—the effect of the relevant gene now depends on the environment. If a child is born in a place that routinely screens for PKU, the gene's effect will often be minimal. Otherwise, the effect will usually be substantial. For today's children, then, the effects of the relevant gene interact (in the formal statistical sense) with socially determined variations in medical care.

Cell II covers sources of variation that have no genetic basis but involve variation in physical rather than social environment. Lead poisoning, which can lead to brain damage, is an example. Again, there is some ambiguity in the classification. While the immediate causes and effects of lead poisoning are physical, the probability of exposure depends on a wide range of social influences. It also depends on skin color. Thus, one could plausibly argue that lead poisoning belongs in Cell IV as well as Cell II.

PKU and lead poisoning illustrate an important general point about Table 1. While we habitually think of certain determinants of test performance as physical "rather than" social, virtually all physical determinants of test performance are themselves to some extent socially determined. Allocating a phenomenon to Cell I or II must therefore be understood not as a denial that social variation leads to phenotypic variation but as an assertion that social factors exert their effects physically.

Cell III covers test-score variations whose exogenous cause is genetic variation but whose proximate endogenous cause is variation in individuals' social environment. "Sexism" is an example. If parents thought it more appropriate for girls to spend their time reading books than for boys to do so, girls might well end up with larger vocabularies than boys. The exogenous cause of this difference would be genetic variation between the sexes. The immediate endogenous cause would be variation in time spent reading.

Cell IV covers sources of variation in test performance that are causally independent of both genes and physical conditions—though they will, of course, often be correlated with both. An individual's native language is an obvious, almost trivial, example. Such differences are the meat and potatoes of social science, so detailed comment should not be necessary.

Cells II, III, and IV cover source of variation in test performance that people commonly label "environmental." Yet these three sources of variation have very different effects on h^2. If most of the variance in a given phenotype derives from Cells II and IV, h^2 will be low. If most of the variance derives from Cells I and III, h^2 will be high. Yet neither hereditarians nor environmentalists are interested in the combined importance of Cells I and III vs. Cells II and IV. They are interested in the importance of Cell I relative to the combined importance of Cells II, III, and IV. What they care about, in other words, is the explanatory power of the "environment," broadly construed, not the explanatory power of "heredity," broadly construed. The two questions have only the most limited relationship to one another. Furthermore, the question we can answer, namely the explanatory power of heredity, is the question we seem not to care much about.

IV. Policy Implications of Heritability Estimates

Geneticists often argue that while genes do not "determine" phenotypes, genes do "set limits" on phenotypes. No sensible person would deny this: genes may not determine height, for example, but they do seem to ensure that nobody will be less than six inches high or more than sixteen feet high. The question, however, is whether these limits are narrower for traits with high heritabilities than for traits with low heritabilities. If the effects of genotype and environment are additive, as virtually all analysts assume, the answer is that h^2 tells us nothing about the relevant limits. In Equation 1, for example, the value of G sets no limit whatever on the value of P. For any value of G there is another value of E that will yield the desired value of P. If a \$100 increase in expenditures raises a pupil's IQ by one point, for example, the additive model in Equation 1 implies that a school board can raise any pupil's IQ to any level it deems desirable, simply by spending more money. This would remain true even if \$100 raised IQ by only 0.01 points.

Most readers will rightly reject models with such unlikely implications. The point, however, is that we know virtually nothing about the limits genes place on specific phenotypes and that knowing h^2 adds nothing to our knowledge of these limits. There is no empirical evidence that genes place narrower limits on traits with high heritabilities than on traits with low heritabilities. Indeed, it is not clear how one would go about comparing the limits genes place on different traits.

In practice, most hereditarians (e.g., Jensen, 1969) make a somewhat different argument. They claim that if a trait or behavior has a high heritability this means that environmental changes are unlikely to have much effect *relative to the existing variance*. This argument is sometimes correct—but only if two rather stringent conditions hold. First, the change in question must affect only exogenous environmental factors, not partially or completely endogenous ones. Second, the change in question must involve reducing or redistributing existing environmental variation rather than increasing such variation or changing conditions that are now uniform.

Since IQ and scholastic achievement have been the focus of most policy inferences based on h^2, they provide a useful illustration of these principles. First, suppose that a school board is trying to assess the likely impact on IQ of abolishing elementary school tracking, and that local studies have shown that IQ has a heritability of 0.80—the highest figure cited by most hereditarians. What can the board infer about the effects of tracking? The answer is, "Nothing." The reason is that children are assigned to elementary school tracks partly on the basis of IQ. Track assignment therefore depends on genotype as well as exogenous environmental influences, and variations in IQ that derive from track assignment contribute to the genetic as well as the phenotypic variance of IQ. Thus, $1 - h^2$ sets no limit on the proportion of variance due to tracking.

For simplicity, suppose that half of all entering first graders have IQ's of 90 while the other half have IQ's of 110, and that all high IQ children are assigned to the "fast" track while all low IQ children are assigned to the "slow" track. Suppose that at the end of six years all children in the fast track have IQ's of 115, while all those in the slow track have IQ's of 85. Abolishing tracking would then seem likely to reduce the variance of IQ by more than half. But the *ratio* of genetic to phenotypic variance—that is, h^2—would remain constant. This would be equally true if at the end of six years all children in the fast track still had IQ's of 110 while all those in the slow track had acquired IQ's of 105, or if all IQ's were the same at the end of school as at the start. An h^2 of 0.80 is thus compatible with tracking helping the advantaged, helping the disadvantaged, or having no effect whatever. Since changes in the effect of track assignment have no necessary effect on h^2, the value of h^2 tells us nothing about the likely effect of track assignment.

In practice, of course, initial IQ is not the only determinant of track assignment. Race, sex, SES, and other factors play a part. But all these factors are also likely to be proxies for an individual's genes. Unless we can determine the degree to which track assignment depends on genes, both directly and indirectly, we cannot say to what extent IQ variance generated by tracking is utilmately traceable to genetic factors. As a result, $1 - h^2$ sets no upper bound on the amount of variance generated by tracking.

In some cases, however, we may have reason to believe—or at least be willing to assume—that some feature of the environment does not vary in response to genotype. Suppose, for example, that a school system assigns pupils to schools on a random basis. Variations in school quality are then clearly exogenous. If $h^2 = 0.80$ in this community, variations in school quality cannot explain more than 20% of the total variance in IQ. Yet even this "fact" has relatively weak implications for policy.

Suppose, for example, that the school board is currently spending $2,000 per pupil and is considering a proposal to set up an experimental school that would cost $3,000 per pupil. Suppose, in addition, that the board knows the standard deviation of current expenditures per pupil is $335 and that it is willing to accept hereditarian claims that $h^2 = 0.80$ for IQ. The equation relating IQ to expenditures (Y), other exogenous environmental influences (X), and genotype (G) is:

$$\mathrm{IQ} = \mathrm{B_1Y} + \mathrm{X} + \mathrm{G} + u. \qquad (12)$$

Taking variances,

$$\mathrm{Var(IQ)} = \mathrm{B_1^2Var(Y)} + \mathrm{Var(X)} + \mathrm{Var(G)} + \mathrm{2Cov(GX)} + \mathrm{2Cov(YX)} + \mathrm{2Cov(YG)} + \mathrm{Var}(u). \qquad (13)$$

But Cov(YX) = Cov(YG) = 0 under random assignment, and by assumption Var(G) = 0.80 Var(IQ). It follows that:

$$\mathrm{B_1^2 Var(Y)} < \mathrm{0.20Var(IQ)}. \qquad (14)$$

Since $\mathrm{Var(IQ)} = 15^2$, and $\mathrm{Var(Y)} = 335^2$,

$$\mathrm{B_1}^2 < \frac{(0.20)(15^2)}{335^2} \qquad (15)$$

or

$$\mathrm{B_1} < 0.020. \qquad (16)$$

A $1,000 increase in expenditures per pupil cannot, in short, increase IQ by more than 20 points. Such an increase may, however, have no effect whatever. This range of possible effects is so wide as to be virtually useless. If the board were to assume a lower value of h^2, its uncertainty about the likely effect of spending more money would be even greater.

A heritability of 0.80 would provide slightly more guidance if the school board were considering eliminating an existing source of variation in IQ. If pupils are currently assigned to schools on a random basis, the school board can be reasonably certain that making all schools equally good will not reduce the variance of IQ by more than $1 - h^2 = 20\%$. Again, however, this is a fairly weak conclusion. If equalizing school expenditures reduced the variance of IQ by 20%, this would be appreciable. If the reduction were 2%, the results would be hard to detect.

Another statistic usually tells more about the likely effect of environmental changes than $1 - h^2$ does. This statistic, which is often denoted as e_c^2, measures the proportion of the phenotypic variance in a given trait attributable to "common" environment. The "common" environment includes those aspects of the environment that are common to all children reared in the same home—or sometimes to twins in the same home—regardless of genotype. Since such features of the environment are exogenous, e_c^2 is always less than $1 - h^2$.

Like $1 - h^2$, e_c^2 tells us nothing about the potential effects of new environments, such as a new school that might spend more than existing schools. It tells us only about the effect of reducing or eliminating existing environmental differences among families. But many policy proposals consist, in essence, of providing all families with advantages currently enjoyed by the privileged. If e_c^2 is initially large for a given phenotype, successful efforts along this line can be expected to substantially reduce the total variance of the relevant phenotype and greatly improve the relative position of the disadvantaged. If e_c^2 is small, such egalitarian policies are unlikely to have dramatic effects on the total variance, though the effects on the very worst-off may still be fairly sizable.

The simplest way to estimate the explanatory power of common environment is to calculate the covariance between pairs of adopted siblings reared together ($\mathrm{CovPP'}_A$). But since adoptive parents are more advantaged than the average parent in terms of SES and other unmeasured traits, they probably provide children with less-variable environments than natural parents do. The covariance between adopted siblings is therefore likely to be less than the variance explained by common environment among natural siblings, though not necessarily much less.

Another way of estimating the common environmental variance is from twin data. Using the notation of Section III, the common environmental variance is equal to Cov(XX′) and $e_c^2 = \mathrm{Cov}(XX')/\mathrm{Var}(P)$. Subtracting $\mathrm{Var}(G_M)$ from both sides of equation 8*M* gives us:

$$\mathrm{Cov}(PP'_M) - \mathrm{Var}(G) = \mathrm{Cov}(XX'_M) - \mathrm{Cov}\,(GX'_M). \tag{17}$$

If the variances for twins are comparable to that for the general population, dividing both sides of equation 17 by Var(P) yields:

$$r_{PP'M} - h^2 = e_c^2 - \frac{\mathrm{Cov}(GX'_M)}{\mathrm{Var}(P)}. \tag{18}$$

Since Cov(GX′) can hardly be negative,

$$e_c^2 \leq r_{PP'M} - h^2. \tag{19}$$

Equation 19 thus sets an upper bound on e_c^2, while $\mathrm{Cov}(PP'_A)/\mathrm{Var}(P)$ sets a lower bound. If Cov(GX′) is sizable (because parental genotype has a sizable effect on X as well as G), or if the restriction of range on X is sizable for adopted children, the discrepancy between these two estimates may be quite large. Nonetheless, for policy purposes e_c^2 is usually a more useful statistic than h^2.

The foregoing arguments underline the point made at the outset of this paper: until we know *how* genes affect human behavior, the mere fact that they account for a substantial fraction of the currently observed variance in such behavior is not very instructive. But suppose we could describe the way in which genes exert their influence in precise detail. Suppose, moreover, that we found genes exerted their effects on, say, IQ largely by affecting children's physical development which, in turn, affected their mental "capacity" in the traditional, mechanical sense. Would this be grounds for pessimism about raising the IQ's of those who now score low? The answer is no, for two reasons.

First, as already noted, if we can identify environmental variables that explain even a small fraction of the existing variance in IQ, we may well be able to increase the means of these variables so that they fall outside their current range. This can increase the IQ's of certain individuals—or of the whole population—substantially. It is true, of course, that most interventions aimed at raising IQ have negligible long-term effects. But this discouraging fact merely dramatizes our inability to identify—or perhaps change—the environmental determinants of IQ. If we *could* change the environmental determinants of IQ, there would be no necessary limit on our ability to raise IQ's, even if h^2 were 0.80. The earlier discussion of school expenditures illustrates why this is so.

Second, even if genes affect IQ by physical rather than social means, this does not necessarily imply that IQ is hard to change. On the contrary, physically determined traits are often *easier* to change than socially determined ones. The case of PKU is illustrative. Once we know how PKU works, we can reduce the damage relatively easily. Few social interventions are anything like as effective. Eliminating "cultural deprivation," for example, would require an egalitarian revolution that is opposed by a large fraction of the population. Limiting the effects of PKU requires only a change in diet—which is cheap, effective, and relatively easy to implement.

There is, of course, no ironclad guarantee that a full understanding of the way in which genes affect a given trait will allow us to intervene effectively in the process. Nevertheless, if we compare past medical and social interventions, it would be hard to argue that social interventions had generally been either easier to implement or more effective than medical ones. Thus, the idea that high heritabilities should be grounds for pessimism is doubly suspect, first because genes may currently exert much of their effect through the environment and, second, because even if genes do not now exert their effect through the environment, environmental changes may nonetheless alter genes' effects in the future.

BRINGING THE FIRMS BACK IN: STRATIFICATION, SEGMENTATION, AND THE ORGANIZATION OF WORK*

JAMES N. BARON AND WILLIAM T. BIELBY
University of California—Santa Barbara

American Sociological Review 1980, Vol. 45 (October):737–765

This essay examines the shift toward "structural" explanations in recent studies of inequality. After reviewing this body of research and some of its shortcomings, we examine its theoretical underpinnings, comparing "structuralist" perspectives on work organization derived from institutional economics and neo-Marxism to more orthodox accounts based on neoclassical and "industrialism" theories. This discussion suggests areas where the different perspectives overlap and diverge. We conclude that work arrangements within the firm and their trend are the focus of most "structural" perspectives on positional stratification; thus, empirical studies grounded at the organizational level are more likely to inform current debates about the "structure of work" than is the growing body of research about structural effects on individual attainment or covariation among industrial/occupational characteristics. Toward that end, an agenda for future research is outlined, focusing on three aspects of work organization: (a) the units which comprise the structure of work and the dimensions underlying economic segmentation; (b) the effects of sectoral differentiation on technical and administrative arrangements within firms; and (c) temporal changes in how enterprises organize production. We provide some illustrations of the kinds of empirical data and research hypotheses required to link research on segmentation and stratification more closely to studies of organizations.

INTRODUCTION

Since Blau and Duncan's exemplary study of *The American Occupational Structure* (1967), stratification research has focused almost exclusively on the determinants of individual socioeconomic achievement. While researchers might acknowledge that attainment occurs within specific structures (e.g., Duncan, 1968:680–2), critics have charged that this body of work ignores the dependence of attainment processes on the structure of positional inequality—that is, the "empty places" in the economy and the relations among them (e.g., Sørenson, 1975; Burawoy, 1977). Indeed, many investigators have maintained that structure is both more important than and logically prior to individual attainment (e.g., Wright and Perrone, 1977; Beck et al., 1978; Snyder et al., 1978; Kalleberg and Griffin, 1980). In recent years, empirical research from explicitly structuralist perspectives has sought to redress the imbalance. Much of this research purports to show that individual achievement is a function of structural factors such as class (Wright and Perrone, 1977; Wright, 1978; Kalleberg and Griffin, 1978; 1980), authority (Kluegel, 1978; Robinson and Kelley, 1979; Wolf and Fligstein, 1979), organizational size (Stolzenberg, 1978), or labor market sector (Stolzenberg, 1975; Bibb and Form, 1977; Beck et al., 1978; Hodson, 1978). We refer to this emerging body of literature as the "new structuralism" in stratification research.

Unfortunately, the "new structuralists" have yet to offer a coherent and consistent representation of the structurally contingent nature of attainment processes (Pfeffer and Ross, 1979; Zucker and Rosenstein, 1980; Granovetter, forthcoming). In our view, this reflects two

This essay is based largely on papers we presented to the National Science Foundation Conference on "Labor Market Structure and Socioeconomic Stratification," University of Georgia, March, 1980. The authors were supported in part by a grant from the National Science Foundation (DAR 79-24905). J. Edmund Phillips of the California Occupational Analysis Field Center has generously and patiently helped us acquire and interpret the data on work organization within firms. Skillful research assistance was provided by Karen V. Hansen. We gratefully acknowledge the comments of Robert P. Althauser, Neil D. Fligstein, and Roger O. Friedland on earlier drafts of this paper.

basic limitations which characterize this research. First, an explicit conceptualization of the structure which underlies and organizes attainment is rarely offered. Instead, we find numerous descriptive interpretations loosely consistent with countless variations upon notions of dual economy, internal labor markets, segmented labor markets, and Marxian class theory, incorporating insights from historiography, institutional economics, organizational theories, and more orthodox approaches to social inequality. Second, most analysts would acknowledge that the relationship between structure and attainment is intimately tied to the *organization of work*—that is, the interplay between technical and administrative imperatives on the one hand, and relations among people, positions, and objects within the workplace on the other. Yet competing perspectives on work organization have not been examined directly in their empirical studies.

We will examine some of these limitations in detail and propose a heuristic scheme for representing how various levels and units of work organization figure in the new structuralism. This discussion inspires a research agenda focusing on *firms* as a missing link in contemporary structural stratification research. We suggest that work is structured at five levels of social organization: societal, institutional, organizational, role, and individual. Correspondingly, social inequality may be examined at five hierarchically connected units of analysis: economy, industry or sector, firm, job, and individual. Within this context, we propose that firms link the "macro" and "micro" dimensions of work organization and inequality. Within firms, labor is priced and allocated, techniques of production are arranged and implemented, and power is organized and executed. Social and economic mobility are achieved within and between economic organizations. Societal and institutional forces impact jobs and workers through the organizational constraints faced by firms; conversely, actions taken by work establishments affect their macro environments. Indeed, the central role of firms in bridging structure and process at various levels of social and economic organization has been emphasized by theorists aligned with such disparate schools of thought as structural functionalism and Marxism (cf. Parsons and Smelser, 1956; Edwards, 1975). Yet the organization of work within (and between) firms has been almost universally ignored in current stratification research. Studies aimed at specifying and testing various perspectives on how work roles are organized (and change over time) have been few and far between, relative to efforts aimed at enhancing our ability to predict individual socioeconomic success. Accordingly, we begin by critically reviewing the substance and method of some representative structural stratification studies.

ADDUCING "STRUCTURE" FROM ITS EFFECTS ON ATTAINMENT: YOU CAN'T GET THERE FROM HERE

The new structuralists have increasingly recognized the need to understand the "structure of work" and how it changes over time *before* studying its effect on individual achievement (e.g., Wright and Perrone, 1977; Beck et al., 1978; Kalleberg and Griffin, 1980). However, the tendency of analysts to confound two questions, "How is work organized?" and "Who gets ahead?" may help explain certain anomalies and ambiguities which plague most recent empirical efforts.

1. Are occupations and industries relevant units of analysis? Occupations and industries appear almost universally in structural stratification research, either as the loci of worker mobility, or in the guise of structural variables influencing earnings, job satisfaction, and the like. Yet the significance of occupational and industrial designations for work organization and individual achievement depends, in turn, on how one thinks work is structured in the first place.[1]

---

[1] This criticism is thus equally applicable to studies which factor analyze industrial and/or occupational characteristics in order to derive sectoral typologies. We suggest below that such operationalizations and measurements of "structure" are less informative than studies which reflect more meaningful distinctions in work organization at the *firm* and *job* levels.

According to most labor market theorists (e.g., Piore, 1975), occupations are relevant for labor market processes only in certain types of craft and administrative employment in which movement occurs predominantly *between* firms and where work performance is regulated by professional norms disseminated through occupational associations, unions, ideologies, and related institutions (Caplow, 1954). Even if occupations *are* relevant units, schemes for classifying them do not necessarily reflect the distinctions among work roles which those who apply such typologies intend to capture. Braverman (1974) and Conk (1978), for example, have convincingly demonstrated that early classification schemes lacked an adequate conception of the technical division of labor among occupations, coming to depend heavily on the very same sociocultural divisions which occupations were presumed to index. Furthermore, while some analysts have defended occupations on the grounds that detailed categories are homogeneous with respect to most salient dimensions of work (e.g., Temme, 1975; Snyder et al., 1978), some evidence suggests that occupations may display far more internal heterogeneity along crucial dimensions than many investigators have acknowledged (e.g., Blaug, 1970; Bridges and Berk, 1974: 213; also see Spenner 1977:70). Others, such as Gordon (1972), claim that the degree of heterogeneity within occupations is itself a part of the historical puzzle to be unravelled by empirical research, rather than a convenient assumption to be imposed by fiat (see Baron, forthcoming). Finally, most theories which buttress the new structuralist research emphasize *jobs* (rather than occupations). Taken together, these arguments militate against analyses of changes in occupational distribution and aggregate occupational characteristics as a means of characterizing changes in the structure of work.

Similarly, industries may be differentially heterogeneous with respect to certain aspects of work. As in the case of occupations, industry boundaries capture meaningful distinctions in work organization only in certain instances. For example, government analysts studying boilermaking in Wisconsin and California for the United States Employment Service in the early 1960s could not even agree whether boilermaking constituted an industry (much less what its defining criteria were) due to the constellation of technological changes, diverse union activities, and administrative arrangements among enterprises engaged in manufacturing and installing boilers (internal memoranda, California Occupational Analysis Field Center, United States Employment Service). Indeed, even when industrial distinctions *are* clear, government experts often find it difficult to determine whether a specific establishment belongs to a particular industry (U. S. Bureau of the Census, 1975: 1.11).[2] Nevertheless, many analysts have assumed industries to be relatively homogeneous with regard to technological and administrative arrangements (e.g., Bluestone, 1970; Spilerman, 1977; Kalleberg et al., 1980; Kaufman et al., 1980; Tolbert et al., 1980). However, numerous organizational studies indicate substantial heterogeneity on these same dimensions within firms and even within departmental units of a single establishment (e.g., Child and Mansfield, 1972; Grimes and Klein, 1973; Billings et al., 1977; Comstock and Scott, 1977), suggesting that the assumption of industrial homogeneity—while no doubt convenient for those analyzing industry-level data—is differentially sensible for certain segments of the industrial structure.

Blaug and his colleagues (1967:18–9) neatly summarized several of these points over a decade ago, criticizing researchers for overlooking

> the crudity of definition of [occupational categories] and the variety of interpretations placed on them by different firms in different industries, and the fact that technology itself permits a variety of educational inputs to the same occupation. The unexamined assumption in most of the literature on manpower

---

[2] Even at the most disaggregated level, industries differ markedly in the extent to which their principal product is produced within the industry and in the degree of product specialization which characterizes firms in the industry (see, for example, the "coverage" and "specialization" ratios provided for four-digit S.I.C. categories in United States Bureau of the Census, 1975: Table 3).

> planning is the stability of occupational classifications, if not across, then certainly within, the various sectors of the economy. . . .
>
> It may be doubted, however, whether the census concept of occupations is sufficiently well-defined to be useable as a research variable. At any rate, it should not be assumed, to say the least, that an analysis of the job content of a particular occupation in one industry would constitute an adequate basis for generalization about all similarly titled occupations in other industries. Indeed, the same argument may well be applied to individual firms within a given industry . . . [since] we know that firms within an industry vary widely in the technical processes they have adopted to produce an identical output.

2. *How do independent variables represent structures and processes?* Not only may the relevant units of work organization depend on one's conception of "structure"; the specification and measurement of how attainments are determined may also depend on structural context. To be sure, some investigators have been mindful of the circularities that arise when characteristics of the work force are included in deriving sectoral typologies which are used, in turn, to explain individual attainment (cf. Hodson and Kaufman, forthcoming; Horan et al., forthcoming). Much less attention, however, has been devoted to specifying precisely how the parameters of the attainment process are dependent on structural influences. Researchers typically disaggregate models of socioeconomic achievement along some structural dimensions (e.g., Wright and Perrone, 1977; Stolzenberg, 1978; Beck et al., 1978), ignoring the possibility that very different factors (not just different regression slopes) may shape allocation and attainment in various structural contexts, or that the interpretation of some parameter may depend on the structure itself. As Granovetter (forthcoming) notes, such processes as income determination reflect at least three types of influences: (a) workers' attributes and choices; (b) employers' decisions and characteristics of jobs; and (c) the process which matches (a) and (b). Structural variables introduced in analyses of individual achievement typically fall under the rubric of (b) above. Yet, as Granovetter argues, the relative *importance* of individual vis-à-vis role attributes, in determining rewards, *itself* depends on how jobs and workers are matched [i.e. (c)], a process which presumably also taps the influence of "structure." For example, Granovetter and others (e.g., Stinchcombe, 1959) argue that features of *roles* are expected to determine the allocation of prestige, income, and other rewards in bureaucratic (core?) enterprises; contrariwise, in the small, decentralized firms characteristic of the so-called periphery, the mechanisms postulated by human capital theorists which link outcomes to *individual* choices and talents are more plausible.

Even if one could legitimately specify the same regression equation for each structural segment, hypothesizing that slopes differ as a function of some contextual factor, the same variable may still represent distinct social and economic processes within each context. Researchers include education, job tenure, and other personal characteristics, for example, in models disaggregated by some structural typology, typically referring to these as "human capital" variables (e.g., Bibb and Form, 1977; Beck et al., 1978; Pfeffer and Ross, 1979; Aldrich and Weiss, 1980).[3] This illustrates precisely the ambiguous notion of "structure" motivating such empirical efforts and may help explain certain anomalous results which have plagued the new structuralism. Many dualists (including some radical segmentation theorists) acknowledge that the secondary labor market and competitive sector approximate the concept of "the market" in neoclassical models of how investments in human capital shape individual career patterns (Doeringer and Piore, 1971; Gordon, 1972; Edwards, 1979). Meanwhile, managerial discretion, bureaucratic imperatives, and objective role requirements embodied in detailed job descriptions purportedly flourish in center firms, suggesting that there education should serve as a credentialling device or means of cultural control—in light of the ongoing political struggles among competing coalitions within such enterprises' (Collins, 1979). Thus, the effect of education may *mean* something very different in each sector.

---

[3] Mark Granovetter reminded us of the theoretical implications of this syntactical convention.

Some researchers have attempted to examine such differences, for example by distinguishing between the effects of years of schooling and the attainment of credentials (Beck et al., 1978; cf. Jencks et al., 1979: chap. 6). However, such efforts still assume that the same specification applies within each sector. More importantly, they do not entirely account for the fact that sectoral differences in the distribution and effects of schooling are neither as substantial nor as systematic as predicted. Data reported by Hodson (1978:452), for example, reveal few striking differences between the monopoly and competitive sectors in the distribution of educational attainment. Bibb and Form (1977:988) found that blue-collar workers in the core had less education than those in periphery industries. Furthermore, Pfeffer and Ross (1979) found little evidence of sectoral differences in the *effect* of education on income and status attainment, regardless of whether segments were delineated in terms of industrial concentration or predominant organizational control strategy ("market" versus "normative" regulation). Some data analyzed by Beck et al. (1978:713) also do not seem to support dualists' claims concerning the influence of schooling and credentials on achievement across sectors.[4] Finally, Kalleberg et al. (1980) found drastically different patterns of association between education and each of four dimensions of industrial segmentation. They also found virtually no evidence that aspects of industrial structure condition the effects of education on income.

In short, we have highlighted the ambiguous definitions and representations of structure in models of individual attainment and have pointed to some anomalous empirical results which reflect those shortcomings.

3. Could these anomalies reflect the new structuralism's inattentiveness to organizational arrangements? The inconsistent findings regarding schooling and segmentation may reflect the cleavage between "good" and "bad" jobs *within* core firms, a split that only modestly differentiates workers in terms of their educational attainment. If primary jobs are largely protected from market competition, and secondary jobs are for the most part homogeneous, then the relationship between education and income within such firms will reflect simply the difference in average education and income between these two classes of labor. In contrast, incremental returns to schooling or vocational training may be attainable through apprenticeship, licensing, credentialling, or career lattices within certain bureaucratic, professionalized, and small craft firms in periphery industries. Consequently, the surprisingly strong relationship, there, between education and income may reflect a more finely graded association between job requisites and rewards.[5]

These speculations illustrate the fact that empirical associations between structure and attainment can be explained only by attending to organizational arrangements within firms. Yet industrial sectors have been defined in a manner which has severed their links to "organizations and organizational properties . . . [even though] it is in organizations that wage and occupational decisions are made, for the most part, and in which mobility and stratification occur" (Pfeffer and Ross, 1979:18). These organizational bases of stratification are largely obscured at the industrial level. Pfeffer's (1977) informative study of wage attainment among students from business schools indicated that the relationship between social origins and destinations is stronger (1)

---

[4] For example, Hauser's (1980) reanalysis of their data indicates that sectoral interactions with respect to the education coefficients are by no means systematic (see his Table 2); indeed, if nonearners are excluded from the analysis, the sectoral interactions vanish altogether (but cf. Beck et al., 1980).

[5] Researchers have also often overlooked the possibility that reliance on formal credentials, internal labor markets, and the like may constitute *alternative* mechanisms of organizational control available to center firms, rather than companion arrangements. Gordon and Thal-Larsen (1969:274), for example, present some interesting data regarding the tradeoff between educational credentials and internal job ladders as means for recruiting (and controlling?) managers within firms.

in staff than in line positions, (2) in small than in large firms, and (3) in nonmanufacturing than in manufacturing enterprises. Indeed, Pfeffer found these three dimensions of organizations which mediate attainment outcomes to be only weakly intercorrelated. According to these results, to the extent that center firms are administratively intense, they should rely on ascriptive background characteristics—rather than education or meritocratic criteria—in promoting within-staff positions. However, ascription is hypothesized to figure less prominently in large firms and manufacturing establishments, presumably in which bureaucratic and standardized operating procedures enhance the utility of educational credentials in allocating and rewarding employees. The fact that income returns to education in the core do not dwarf those observed in the periphery may thus reflect the manner in which distinct dimensions of organizations have been overlooked in empirical examinations of industrial segmentation.[6]

Once we appreciate the fact that the meaning of a variable (such as education) may depend on its "structural context," and that its effects may be masked in analyses which are inattentive to *organizational* processes, we can perhaps make sense of other anomalous findings in the structural stratification research literature. For example, while dualist and segmentation theorists have underscored sectoral differences in the distribution of job tenure and its consequences for income determination, the empirical results have generally failed to support these hypotheses. Pfeffer and Ross (1979) discovered no sectoral differences in the effect of men's tenure with current employers on their income or status attainment. Indeed—while certain "core" industries (e.g., metal, petroleum, and railroad transportation) are characterized by high median levels of employee tenure with the firm—workers in agriculture, leather products, and certain public utilities, as well as females in the paper-products industry, are among those with the longest tenure with their employers (United States Department of Labor, 1975:Table E), despite the fact that such forms of employment are frequently banished to the "periphery" sector (see Zucker and Rosenstein, 1980:Appendix A). As in the case of education, the significance of job tenure for attainment outcomes has been confounded in empirical studies which fail to link job tenure to its specific occupational and organizational bases. Kalleberg et al. (1980) demonstrate the importance of attending to such links. For example, they find that tenure with a firm *is* strongly related to establishment size and industrial concentration but *not* to the economic scale (profitability) of an industry, arguing that the former variables capture the prevalence of internal labor market arrangements within *firms*. Tenure was also negatively related to the proportion of an industry's goods purchased by the state. The authors explain this result by observing that industries selling goods to the state tend to employ higher proportions of professionals and craftspersons, who are more likely to view the occupation, rather than the employer, as a source of career advancement. Thus, they are also likely to change firms more frequently.

Organizationally informed analyses may help clarify yet another anomaly in the empirical literature relating segmentation to individual careers—namely, why unemployment would be higher in core vs. periphery industries (e.g., Beck et al., 1978). Focusing on the basis of control exercised over various classes of workers, and its relations to *types* of unemployment, Schervish (1980) demonstrates that in the primary sectors *jobs* are unstable, while, in the secondary sector, *workers* exhibit employment instability. Schervish's Marxian orientation, emphasizing the basis of control exercised over various class segments, implicitly reflects an organizational focus, underscoring, again, the importance of firm-level processes in mediating societal and industrial forces.

---

[6] Like Stolzenberg (1978) and others, Gordon and Thal-Larsen (1969) found an overall relationship between size of establishment and reliance on education and other formal requirements in recruiting and promoting employees. However, they suggest that the relationship is actually somewhat spurious, obscuring the specific organizational bases of the observed association. They argue that large firms also tend to be more unionized and to be branches or corporate headquarters (rather than single unit establishments), both of which serve to enhance their reliance on formal credentials.

In sum, by ignoring the organizational bases of stratification processes, "structural attainment research" has perhaps overstated or obfuscated sectoral differences in the distribution and consequences of such factors as education, job tenure or internal labor markets, and unemployment (also see Gordon and Thal-Larsen, 1969:325–31; Cassell et al., 1975; Director and Doctors, 1976; Steinberg, 1975; Leigh, 1976a; 1976b; 1978; Spilerman, 1977:583–4; Edwards, 1979:169). In our view, more frequent or elaborate attempts to disaggregate models of socioeconomic achievement, or to factor analyze industry-level data, are unlikely to improve our understanding of how work roles are structured and shape individual biographies. Rather, we suggest that debates about the structure of work can best be advanced by clarifying the areas of conflict and complementarity among competing perspectives on work organization, specifically regarding the role of firms in mediating the links between social structure and processes at macro and micro levels. Below we examine how various accounts of work and inequality differ in emphasizing specific levels of social organization, units of analysis, and relations among them. Having placed these perspectives within such a heuristic framework, we assess where they overlap and diverge, motivating a research agenda which provides more content and coherence to the emerging body of structural theory and research on work organization and inequality.

STRATIFICATION AND WORK: LEVELS OF SOCIAL ORGANIZATION AND UNITS OF ANALYSIS

Research on work and inequality spans levels of organization from individual behavior (e.g., mobility) to the dynamics of entire social systems (e.g., class relations and technological change). As a heuristic, Table 1 arranges five levels of social organization from macro to micro: societal, institutional, organizational, role, and individual. It also presents corresponding units of analysis in studies of work: economy, sector, firm, job, and worker. The table is *not* a conceptualization of work structure, but the centrality of firms within it does suggest that the micro and macro forces affecting work are played out within the organizational arena of the firm. Further, it provides a means for imposing some semblance of order on the myriad empirical findings and conceptual ambiguities one encounters in the new structuralist research.

Table 1. Levels of Social Organization and Units of Analysis in Accounts of Work Organization

Level of Social Organization	Unit of Analysis
Societal	Economy
Institutional	Sector (market, industry)
Organizational	Firm
Role	Job
Individual	Worker

Orthodox attainment studies, according to our scheme, focus on individual workers as units of empirical analysis, but their theoretical concerns embrace both individual and societal levels of organization. At the macro level, the modernizing influence of technical differentiation is seen as undermining ascriptive sources of inequality that persist from an earlier era (e.g., Blau and Duncan, 1967:429). Consequently, an important concern of research at the individual level is the degree to which nonmeritocratic sources of intergenerational status persistence are attenuated by the technical demands of a "postindustrial" society (e.g., Featherman and Hauser, 1978:308–11).

As we noted in the previous section, empirical research by the new structuralists generally examines whether supraindividual units of analysis influence (or dominate) the process of individual achievement. The empirical design in such studies is straightforward (essentially an analysis of covariance), and the relations between units of analysis quite obvious: processes defined over individual units are contingent upon classification according to some more macro unit. But the correspondence between units of analysis and *levels of social organization* is by no means self-evident in this research. For example, Marxian class categories denote ownership (and control) at the societal level. But explanations of class differences in attainment processes typically refer to firm-level (organizational) decisions implemented by capitalists and managers regarding the distribution of power and opportunity, in turn affecting job (role) conditions and the relations among jobs and workers. In short, Marxian variants of the new structuralism (e.g., Wright and Perrone, 1977; Wright, 1978; Kalleberg and Griffin, 1978; 1980; Robinson and Kelley, 1979; Aldrich and Weiss, 1980) pose class mechanisms at the societal level which influence individual attainment (worker units) through imperatives acting upon institutions (industries and sectors), organizations (firms), and roles (jobs).[7] But the organization of work within firms and the attributes and relationships among jobs are often bypassed in empirical applications of Marxian concepts to stratification concerns.[8]

Robinson and Kelley (1979:38), for example, sought to assess the veracity of Marx's and Dahrendorf's accounts of the "more conflict oriented aspects of stratification stemming from the hierarchical organization of work" in the United States and Great Britain. It is curious that the debate among these two perspectives—which centers around the relationship between technical and organizational imperatives in the workplace—should be reduced to regression models with dummy variables indicating how many subordinates one has and whether or not one has a supervisor or employer. According to Dahrendorf (1959), an emergent hierarchy of *technical skill* within the working class ostensibly makes obsolete Marx's rendition—which hinges on the gradual substitution of capital for labor and the concomitant deskilling, homogenization, and unification of the proletariat. In short, the two theorists disagree about both the overall trend in work organization *and* the relationship between technical, administrative, and political imperatives in the workplace. Had Robinson and Kelley focused on how technology and social relations of production within the firm combine to shape worker attitudes and attainments—and how the role of each has changed over time—perhaps they might have achieved a closer correspondence between their empirical results on the one hand and the levels of organization and units of theoretical concern on the other.

The correspondence between units of analysis and levels of social organization is even more ambiguous in empirical research motivated by non-Marxian "dualist" and "segmentation" perspectives. Institutional economists have variously differentiated jobs, firms, labor markets, and industries into segments or sectors. Averitt's (1968) widely cited work, for example, distinguishes between center and periphery *firms* based on their organizational resources and their resulting ability to manipulate institutional environments. While many center firms are located in certain key *industries* (p. 66), "it is economic size, not industrial location, that defines firms in the center economy." Bluestone (1970), Piore (1975), Edwards (1979), and others differentiate *labor markets* into primary and secondary segments. According to these schemes,

---

[7] Thus, like adherents of the "industrialism thesis," many Marxists derive and analyze micro level processes from transformations presumed to operate at macro levels. Of course, a complete Marxian account would encompass the dialectical relations between individual and societal level relations. However, the feedback effects of individual workers on the seemingly deterministic control imperative have only recently been considered in neo-Marxian accounts of work organization (e.g., Aronowitz, 1978; Burawoy, 1980).

[8] To be sure, Marxists recognize that the "logics" of capital accumulation and class struggle (at the macro level) permeate institutions, organizations, and roles in affecting the life chances of individual workers. Industrial structure is seen as increasingly bifurcated between monopolistic and competitive sectors, reflecting the concentration and centralization of capital, the political power exercised by industrial elites through interlocking corporate directorates, and State intervention on their behalf (Baran and Sweezy, 1966; O'Connor, 1973). Struggles within and among unions at the industrial and firm level are seen as fragmenting the working class (Aronowitz, 1973), as are efforts by owners and managers to deskill and homogenize work at the enterprise and job level (e.g., Braverman, 1974; Marglin, 1974; Stone, 1974). But empirical efforts to link Marxian theory to stratification outcomes rarely model the effects of such intervening forces.

the pricing and allocation of labor and the linkages among jobs both within and between firms differ markedly across labor market segments. Empirically, jobs in primary markets are most often situated in center firms and key industries, while jobs in secondary markets occur disproportionately in periphery firms and competitive (O'Connor, 1973) or unconcentrated (Bluestone, 1970) industries.

In short, theories of dualism and segmentation suggest quite a number of conceptual and empirical links between sectors, firms, jobs, and the labor markets through which individual workers obtain employment, but schemes for differentiating jobs, firms, and industries are by no means interchangeable. Unfortunately, the new structuralists have, for the most part, been inattentive to *differences* among perspectives in the levels and/or units emphasized, and the mechanisms posited to link them. Instead, as we have suggested, the dualism and segmentation literatures have served to rationalize various ad hoc schemes for assigning workers to sectors, most often simply on the basis of crude industrial classifications. Far from revealing how work arrangements are structured at various levels of social organization—a principal concern of these institutional approaches—such research efforts at best provide a "reduced form" representation of the structure of work and its effects on individual attainment. Below, we examine more closely the causal imagery of the dominant perspectives on work organization, relying on our heuristic scheme to determine the areas of consensus and disagreement among them.

CLARIFYING THE ISSUES: CONFLICT AND COMPLEMENTARITY AMONG PERSPECTIVES

Though often overlooked, a coherent statement of how work is arranged at different levels of organization can be found (at least implicitly) in conventional studies of achievement. The thesis of "industrialism," which underlies most status attainment research, does not ignore "structure," but differs radically from the stance of its structuralist critics. Consider how Blau and Duncan (1967:429) conclude:

> The basic assumption underlying these [empirical] conjectures is that a fundamental trend toward expanding universalism characterizes industrial society. Objective criteria of evaluation that are universally accepted increasingly pervade all spheres of life and displace particularistic standards of diverse ingroups, intuitive judgments, and humanistic values not susceptible to empirical verification. The growing emphasis on rationality and efficiency inherent in this spread of universalism finds expression in rapid technological progress and increasing division of labor and differentiation generally, as standards of efficiency are applied to the performance of tasks and the allocation of manpower for them. The strong interdependence among men and groups engendered by the extensive division of labor becomes the source of their organic solidarity, to use Durkheim's term, inasmuch as social differentiation weakens the particularistic ingroup values that unite men in common bonds of mechanical solidarity.

It is clear from this passage that the industrialism thesis infers micro level phenomena from macro level processes. As we suggested above, at the *societal* level social differentiation generates change, including transformations of work. Indeed, the application of technical rationality eventually makes work—specifically, occupational roles—the most salient characteristic defining individuals' positions in the social structure (Blau and Duncan, 1967:6; Treiman, 1977:chap. 1). Technical proficiency and individual performances increasingly become the bases for allocating persons to those roles.

According to this thesis, *organizations* are simply microcosms of society (Blau and Scott, 1962). As societal differentiation progresses inexorably, organizations approach the Weberian ideal-typical bureaucracy in which calculable rationality is applied to the organization of work (Parsons and Smelser, 1956:113; Treiman, 1977:9–11). Blau et al. (1976:39–40), for example, succinctly suggest how industrialism operates at the level of the firm:

> As education expands further and growing proportions of the labor force acquire technical and professional competence, the adaptation of computer technologies to pro-

> duction and office work will undoubtedly take these higher skills into account. While it is possible to automate many operations without raising the skills workers use, a highly trained labor force makes this increase unnecessary. Hence, one can expect the growing automation of factories to raise the level of skill and responsibility of workers.

Correspondingly, this perspective views the *institutional* structure of industrial sectors as a reflection of how the technical division of labor has advanced historically from agriculture to manufacturing to information-based services as the center of economic and social organization (Clark, 1951; Kerr et al., 1964; Lenski, 1966; Bell, 1973).

The dominant perspective on work organization among economists—neoclassical micro theory—has its own version of the technological imperative. Neoclassical theories of the firm also assign primacy to rationalization and technological progress, but are more clearly grounded at the organizational level of analysis. The firm's production function expresses a technical relationship: the amount of output produced by different combinations of factor inputs. Given the prices of output and factor inputs, profit-maximizing enterprises employ each factor until the marginal contribution to firm revenue no longer exceeds the marginal cost of using the factor. The mix of factors, including different types of capital and labor, is solely a function of their relative productivities and prices. The supply of job relevant individual abilities, preferences, and human capital endowments combines with the derived demand for labor generated by firms' productive efforts, thereby linking individuals, roles, and organizations (Addison and Siebert, 1979). At the institutional level, the market structure of an industry is derived either from technical relationships at the organizational level (e.g., declining long-run average costs) or from exogenously imposed conditions such as governmental franchises (Hirschliefer, 1976:275). Similarly, the societal level impinges on the theory in the guise of aggregate "general equilibrium," constrained by external arrangements effected by government, geography, international trade, and the like.[9]

In attempting to redress the individualistic flavor of industrialist and neoclassical approaches to inequality and work organization, the new structuralist research has often drawn on insights from Marxian, institutional, and/or organizational frameworks. However, too little attention has been focused on how (or whether) the latter cohere into a unified alternative conceptualization of the structural bases of stratification. Accordingly, we think it prudent to compare how these perspectives embrace each level of social organization.

We have already noted how Averitt (1968) defines the dual economy by distinguishing between center and periphery firms. The linkage with institutional and societal levels is established by what might be called "dualist historiography" (Berle and Means, 1932; Chandler, 1962; 1977; Shepherd, 1975; Caves, 1980). It is claimed that firms implemented mass and process technologies and initiated new strategies of coordination and control as an adaptive response to changing markets. But not all firms experienced the combination of market, technical, and administrative preconditions which made it possible to adopt the new form of corporate structure—that is, decentralized, vertically integrated, multidivisional, diversified, etc. (Chandler, 1962). The requisite conditions occurred most often in certain key industries (Averitt, 1968), resulting in a new institutional order of industrial *sectors*. Galbraith (1967; 1973) and others have linked these developments to the *societal* level by emphasizing the emergence of the planning function within large corporations and the state, which, in turn, shapes the national (and international) economy and polity.

---

[9] While the application of technical rationality is central to *both* neoclassical and industrialism approaches, the former perspective is less "structural," predicated upon the rational maximization behavior of individual economic agents. Institutional and societal phenomena are simply aggregations of that behavior. In contrast, social differentiation "drives" the industrialism thesis at the societal level, as the irreversible progress of the division of labor is played out at more micro levels of organization.

Neo-Marxian and dualist accounts stress some of the same processes and mechanisms, but the perspectives vary in assigning priority to different levels of social organization (Gordon, 1972:85–96). As we have indicated, neo-Marxists typically start with class relations and capital accumulation at the societal level and derive implications for micro levels of social organization. However, dualists begin at intermediate levels—role, organization, sector—from which societal and individual level consequences can be derived. Theories of *internal labor markets* link the organizational, role, and individual levels in dualists' accounts of work. Job ladders define promotion, skill, and supervision hierarchies within the firm, and the need for minimal labor turnover determines which individual attributes become the criteria for selection into entry level jobs (Thurow, 1975). Small periphery establishments without internal labor markets supposedly have job structures which differ markedly from those found in center firms—few well-defined promotion lattices, fewer levels of supervision, and relatively low skill requirements. Individual attributes such as "trainability" and long-term commitment to the firm should be less important criteria for selection into jobs in the secondary labor market (Freedman, 1969; 1976; Doeringer and Piore, 1971; Gordon, 1972; Harrison, 1972).

While both neo-Marxian and dualist explanations are often posed in opposition to those of neoclassical economics or attainment research (Gordon, 1972), it is not always clear how (or if) the different views directly conflict. For example, the processes represented by "deskilling" and the "control imperative" might be viewed simply as elaborations of the calculus of marginal substitution whereby capital replaces labor (or vice versa). Such a neoclassically inspired perspective would explicitly recognize the costs of administrative uncertainty introduced whenever labor is employed as a factor in production. Similarly, neoclassical economists have long recognized the consequences of skill specificity for training, labor turnover, and advancement, which are not inconsistent with the notion of internal labor market structures (Oi, 1962; Becker, 1964; Rosen, 1974:438; Wachter, 1974).

Perhaps the most conspicuous and significant disagreements among these diverse perspectives concern the causes of the historical development of work. While both the industrialism thesis and neoclassical theory regard contemporary economic organization as an outcome of increasingly rationalized and efficient productive arrangements, neo-Marxists argue that the logic of capitalism embodies a social control imperative within that technical division of labor. Task differentiation and the substitution of capital for labor are not simply matters of engineering and economics, confined to the realm of production functions and the calculus of marginal costs and revenues. Rather, division of labor and automation of production are implemented in a manner which also maximizes the control of capitalists and managers over the production process. The control imperative brings about the separation of work conceptualization from execution, a homogenization of labor which artificially differentiates work in a manner only loosely related to skill differentials (Braverman, 1974), the implementation of internal labor markets to placate and regulate workers in monopoly industries (Stone, 1974), and creation of a reserve army of the unemployed to help "discipline those inside the factory gates" by posing a threat to their job security (Gordon, 1977:94).[10]

Neo-Marxian accounts thus typically regard work arrangements as outcomes of the logic of capital in which social control is inextricably linked to accumulation and profit extraction. While couched within a broader historical view, Marxian theory also suggests specific expectations regarding *contemporary* work organization. Note, for instance, that the logic of job fragmentation and hierarchy fetishism implies the existence of more highly differentiated and authoritarian work structures within certain firms than could reasonably be ascribed to considerations of technical efficiency. Thus, disagreements among perspectives largely reflect different views of the decision-making process *within firms*, especially with regard to the adoption and management of innovations in the workplace. For example, some argue that internal labor markets are established for reasons of technical efficiency (Doeringer and Piore, 1971), while others emphasize their functions as mechanisms of social control (Stone, 1974). Approaching employment relations in terms of the features and costs of "transactions" within the organization, Williamson (1975:72–81) derives an explanation of the same structural arrangement which entails *both* its efficiency and control aspects. Hence, even if the structuralists were to subject the internal workings of organizations to detailed empirical scrutiny, it is not clear that their findings would indicate which of several structural perspectives is most viable. As David Gordon (1972:129–30) notes, it is difficult to discover employer motivations regarding the design of work; one must rely on indirect inferences. In addition to historical case studies he suggests that

---

[10] There seems to be an inconsistency between radical and internal labor market perspectives on this matter. Doeringer and Piore (1971) and others maintain that firm-specific skills are a crucial feature of jobs in internal labor markets, and that nonentry level jobs are insulated from wage competition (Thurow, 1975). In that situation the "reserve army" poses little threat, since its members are not substitutes for the specifically trained workers protected by internal job ladders. Thus, workers as well as employers in center firms may develop an interest in maintaining organizational arrangements which in effect export the threat of the reserve army to the periphery.

> one might try to infer from comparative studies some evidence about the direction of employer choices. Given firms which employ the same technologies in different social settings, one might try to adduce something about the consequences for job design of alternative social objectives.

Further, Gordon underscores the irony that most analyses which have sought to contrast Marxist, dualist, and more orthodox accounts have relied primarily on macro level data, even though these perspectives can most readily and meaningfully be contrasted by analyzing firms and their internal workings. Much of the new structuralism has been inattentive to the different models of administrative decision making which underlie competing perspectives. Investigators have sought to address debates about the distribution and consequences of authority, power, or social control within firms without considering the ways in which hierarchies are arranged or implemented at the organizational and suborganizational level (Wright and Perrone, 1977; Kluegel, 1978; Stolzenberg, 1978; Robinson and Kelley, 1979; Wolf and Fligstein, 1979). For example, without knowing explicitly how managers define, price, and evaluate different types of labor (including management itself) and the respective productivity of each type, it is impossible to discriminate satisfactorily between accounts of deskilling which stress utility maximization of a dominant managerial coalition on the one hand (e.g., Galbraith, 1967; Chandler, 1977) and those which emphasize capital's inherent logic of exploitation and hegemonic control (e.g., Braverman, 1974; Edwards, 1979). For this reason, it is specious to infer support for a particular account of work organization simply from evidence which is not inconsistent with competing viewpoints (cf: for example, Snyder et al., 1978; Baron, forthcoming).

These disputes are not without consequences for ongoing debates among students of structural aspects of inequality. Specifically, analyses of the structure of work and how it changes over time embody some assumptions (most often implicit ones) about *who* decides how work will be organized and what *criteria* are employed in making those choices. Thus, differences among structuralist perspectives often reduce to disagreements about what motivates those who decide on behalf of the firm.

BRINGING THE FIRMS BACK IN: ORGANIZATIONS AND THE STRUCTURE OF WORK

If firms are indeed "where the action is," then social scientists interested in the structure of social inequality should find the vast literature on complex organizations illuminating. Surprisingly, with just a few exceptions, the literature on organizational structure, technology, and social control has been largely ignored in both new structuralist empirical research and dualist theory. To be sure, organizational sociology provides an implicit or explicit rationale for the topics examined in a number of structural analyses. However, as we noted, many such studies are linked to organizational theory merely by virtue of including authority variables within individual attainment models, even though the organizational context within which authority is exercised is ignored. Indeed, almost all structural stratification research addressing "organizational" concerns focuses on the consequences of a person's location within the firm for his or her attainment (e.g., Talbert and Bose, 1977; Halaby, 1979; Rosenbaum, 1979), but not on the relationship between an individual's tasks and position on the one hand, and those of supervisors, subordinates, and co-workers on the other. In short, there is little attention to how work is actually arranged within enterprises.[11] Interfirm differences in work organization either are expressed in terms of some single dimension, such as size, or are dismissed altogether (as in studies of "industry effects").

Yet even a superficial overview of the organizational literature sensitizes one to the difficulties encountered in accurately characterizing organizational structures and processes. Concepts and measures of technology have been intensely debated (Bright, 1958; Amber and Amber, 1962; Woodward, 1965; Perrow, 1967; Hickson et al., 1969; Lynch, 1974), to say nothing of its relationship to the internal structure of the organization (Aldrich, 1972; Child, 1972; Van de Ven and Delbecq, 1974; Blau et al., 1976). Even such a seemingly straightforward concept as organizational size—which figures prominently both in theories of dualism (Averitt, 1968) and empirical applications (Bibb and Form, 1977; Stolzenberg, 1978; Aldrich and Weiss, 1980; Kalleberg et al., 1980; Kaufman et al., 1980)—has generated about as much debate (still unresolved) in the organizations literature as has "class" in the stratification literature (see Kimberly, 1976, for an overview). Furthermore, as noted earlier, the claim of structural and technological homogeneity within organizations or industries—assumed in most sociological and economic accounts of work—is inconsistent with recent research.

Despite problems of conceptualization and measurement, there are also several provocative organizational analyses of the relationship of technology and size to alternative strategies of power and dominance within the firm (Burns and Stalker, 1961; Indik, 1964; Blauner, 1964; Pondy, 1969; Child, 1973; Freeman, 1973; Ouchi, 1977), often focusing on issues strikingly similar to those raised in studies of segmentation and labor stratification. Most importantly, "profit maximization" as an administrative imperative has been criticized from a variety of theoretical standpoints. Typically, institutional economists formulate the challenge in terms of a dichotomy between models of "profit maximization" and "utility maximization" or "managerial discretion" (Williamson, 1963; 1975; Galbraith, 1967; Pondy, 1969). Radical economists (e.g., Gordon, 1972; 1976; Marglin, 1974; Edwards, 1975; 1979) juxtapose "qualitative" and "quantitative" efficiency; like dual labor market theorists, they (Gordon, 1972:129–30) suggest

> that there is a frontier of job design possibilities, given a specific technology, which promise[s] equally efficient production in output per worker terms. Employers then choose a point of production organization along the frontier which satisfies some other objectives. One can easily hypothesize, especially from the radical perspective, that employers choose along the job design frontier in order to maximize the stratification of labor and to minimize class consciousness within the potentially most dissatisfied strata.

However, based on organizational theory, one can also easily hypothesize that employers choose to pursue some other objectives in addition to (or instead of) profits. As the institutional (and some neoclassical) economists argue, managerial discretion may be applied to administrative decision making in order to maximize a utility function which includes managers' (or owners') preferences for growth, maximum sales, perquisites, stability, or even for the proliferation of management itself (see Nicholson, 1978:269–77 for an example of how neoclassical orthodoxy treats alternatives to the hypothesis of profit maximization). Alternatively, managers may "satisfice" (Simon, 1957)—that is, adopt some strategy (optimal or otherwise) which fulfills their aspirations, based on limited information. Or employer choices may perhaps affect outcomes only through a complex process of intraorganizational negotiation among potentially competing coalitions (Cyert and March, 1963; Leibenstein, 1979).

---

[11] A noteworthy exception is the research by Melvin Kohn, Carmi Schooler, and their associates (e.g., Kohn and Schooler, 1973; 1978; Miller et al., 1979) which examines the relationships between "structural imperatives of the job" and workers' psychological functioning. However, these structural imperatives (e.g., "ownership," "organizational locus," and "occupational self-direction") span several levels of social organization. Furthermore, this research has focused primarily on the causes and consequences of individual psychological "attainments" (e.g., intellectual flexibility), treating the imperatives of work as exogenous.

In short, since the distribution and dispensation of *power* within firms are central foci of competing theories of work organization and stratification, researchers interested in the structures which frame socioeconomic achievement can ill afford to continue treating firms as "black boxes" in their empirical analyses (Pfeffer, 1977; Stolzenberg, 1978; Pfeffer and Ross, 1979). Extant theory and data pertaining to the organization of work certainly preclude any definitive analyses of the relative merits of reigning structuralist perspectives. Nonetheless, a great deal could be gleaned by examining the relative veracity of competing accounts through empirical studies addressing: (1) the dimensions which differentiate work settings; (2) the relationship between organizational characteristics and linkages among jobs; and (3) how (and *why*) the structure of work roles within a firm changes over time. For example, do technical and administrative arrangements within firms reflect a cleavage between monopolistic and competitive industrial sectors? Do relations among jobs within large center firms reflect more detailed and clearly defined layers of promotion, skill, and dominance than in periphery enterprises? Do changes in work organization over time indicate the operation of an incipient control imperative—manifested in deskilling and/or homogenization of labor—which is not reducible to the marginal calculus of neoclassical micro theory?

These concerns conspicuously highlight the importance of *organizations* as the crucial entities within which work is structured and underscore the relevance of the literature on complex organizations and administration for debates about the causes, trends, and consequences of positional inequality. It may be that characteristics of individuals are easier to conceptualize and measure than are attributes of the "empty places" within the stratification system (cf. Burawoy, 1977), perhaps explaining both the emerging consensus among researchers about the need for analyses of "structure" and their lack of agreement on how to undertake them. In the following section we outline a course for future structural studies; to demonstrate the feasibility of our suggestions, we restrict our discussion of hypotheses and models to those capable of being examined with *extant data*, using examples from our own ongoing research as illustrations (Bielby and Baron, 1979; 1980).

A RESEARCH AGENDA FOR THE "NEW STRUCTURALISM"

The Contours of Dualism: Units Comprising the Structure of Work

This essay has suggested that researchers employing dichotomies (or polychotomies) of sectors, markets, occupations, industries, and the like have often devoted too little attention to *what* is being dichotomized—that is, at which levels of organization and from which units work is structured. Since the fondness of stratification researchers for achievement studies employing sectoral typologies seems to be increasing inexorably, we suggest that detailed empirical studies of how (or whether) dualism or segmentation is constituted are an essential precondition for making sense of the new structuralism. As argued above, occupations and industries are quite heterogeneous, and are of limited relevance to many of the structuralists' concerns.

Therefore, we suspect that job- and firm-level analyses can more meaningfully portray the structure of work than can the growing literature analyzing occupational or industrial data (e.g., Rosenberg, 1975; Freedman, 1976; Lowell, 1978; Oster, 1979; Kaufman et al., 1980; Tolbert et al., 1980; Wallace and Kalleberg, forthcoming).[12]

An illustration: The dualist and segmentation literatures (e.g., Averitt, 1968; Bluestone, 1970; Gordon, 1972; Edwards, 1975) suggest that the attributes of firms listed in Table 2 are among those which should differentiate economic sectors.[13] Preliminary support for the dualism hypothesis would be provided if such characteristics successfully discriminate among industries and if the latter cluster into clearly bounded sectoral groupings. Since firm-based dualism is conceptually distinct from industrial differentiation, and, given the remarkably weak consensus among several industry-based schemes for classifying sectors, we would not expect to find overwhelming evidence of dualism at the *institutional* level of analysis. Furthermore, while many of these bivariate hypotheses are plausible, we have argued in this essay that sectoral differences in work organization have been overstated.[14] For example, while dualist and segmentation approaches regard the center/periphery distinction as approximately dividing the labor force in terms of skill (see Table 2), we expect such overall differences in skill *level* to be small. Research by Blauner (1964), Bright (1958), and others indicates that the transition to highly capitalized and/or automated technologies—such as those which purportedly characterize the core—do not necessarily engender any monotonic rise in skill levels, although they do appear to increase the *variation* in workers' skills.[15]

Thus, our aim in formulating and testing these hypotheses would be neither to "prove" nor to "refute" structuralist theories of work and inequality, but rather to provide a more detailed specification of where the organization of work does and does not correspond to their predictions. Moreover, while such theories typically base their sectoral distinctions on different patterns of work arrangements, most industrial data used to derive sectoral typologies (e.g., mean assets, business receipts, state purchases) are proba-

---

[12] To study the structure of "empty places" or work roles, we need to develop methods for acquiring and analyzing data on positions rather than on individuals. Our own work in progress utilizes data describing jobs and work establishments in California collected by its Occupational Analysis Field Center for the United States Employment Service. Since the late 1950s, the Employment Service has conducted field visits of establishments in over 100 industries, obtaining complete enumerations of all jobs within firms; the administrative and technical structure of each establishment; the sex composition, educational and skill requirements, and psychological concomitants of jobs, as well as their placement within networks of promotion, supervision, transfer, and vocational preparation. "Narrative reports" furnish a wealth of qualitative information about establishments' formal and informal personnel practices; collective bargaining arrangements; corporate age, history, and structure; production processes and departmental organization; firms' relations to automation, product markets, parent companies; and related matters. A number of enterprises were also revisited some five to ten years later, providing follow-up data with which to analyze temporal changes in work organization. The empirical illustrations which punctuate this research agenda are based largely on our continuing analyses of these data. (For a full description of this data source and how key variables are operationalized, see United States Department of Labor, 1972; Bielby and Baron, 1979).

[13] With the possible exception of "production continuity," the attributes listed in Table 2 should be familiar to students of stratification and segmentation. See Blauner (1964), Meissner (1969), and Caves (1980) for representative overviews of this concept and its consequences for work organization.

[14] It should be apparent that we expect a number of these attributes to vary substantially *within* firms, even though they are frequently used as criteria for characterizing (or even defining) economic sectors. Accordingly, we expect empirical analyses of hypotheses such as those listed in Table 2 to demonstrate two things: (1) that differences among sectors in the *level* of certain attributes are modest; and (2) that industries, firms, departments, and jobs each display substantial heterogeneity not captured by current sectoral schemes.

[15] Kalleberg and his colleagues (1980) regressed occupational skill (SVP) on a series of individual demographic and work experience variables and four dimensions of economic segmentation. Net of the person-level factors, they found that while economic scale of an industry and relative state consumption of its product had positive effects on SVP, concentration had no effect, and establishment size exercised a substantial *negative* influence (also see Baron and Bielby, 1980).

Table 2. Hypothesized Distributions of Firm Attributes by Sector

Firm Attribute	Sector	
	Core	Periphery
1. Scale of operations	Large	Small
2. Vertical integration	High	Low (or absent)
3. Division of multiestablishment organization	Yes	No
4. Skill level	High	Low
5. Skill dispersion	Dispersed	Homogenous
6. Internal labor markets	Yes	No
7. Task complexity	Complex	Simple
8. Social control (mode of supervision)	Bureaucratic	Simple hierarchy
9. Collective bargaining contract	Yes	No
10. Production continuity	High	Low
11. Capital intensity	High	Low
12. Sex composition	Predominantly male	Predominantly female

bly less representative of how work is actually organized within firms than are variables such as those listed in Table 2. To test this assertion, one could compare a multidimensional configuration of industries based on such job and firm attributes against one based on the industry-level variables typically used to determine sectors.[16] If these configurations differ, then schemes in which distinctions among firms are subsumed completely at the industrial level are likely to obscure important sectoral divisions at the organizational level.

Having thus investigated "industrial dualism," segmentation among organizations could be further explored by examining the distribution of firms on the attributes listed above. For example, analyses of the covariation among firm attributes should differentiate firms in a manner consistent with the twelve bivariate hypotheses listed in Table 2. Organizationally based dualism would be evident if firms clustered into center and periphery sectors in the resultant multidimensional space. If, as Averitt argues, dualism is generated by differences among firms and the institutional structure is not strictly demarcated by industries, then a specific pattern should emerge from the analysis of industrial differentiation proposed above. First, firm attributes should discriminate moderately among industries; second, *firms* should exhibit stronger tendencies toward sectoral clustering than do industries. Furthermore, industries with ambiguous sectoral locations should be precisely those about which there is most disagreement in the various a priori schemes for assigning industries to sectors (see Zucker and Rosenstein, 1980).

Finally, a parallel analysis would discriminate firms on the basis of *job* attributes that are presumed to vary between center and periphery. For example, task specificity and complexity, promotion opportunities, bureaucratic control, and male composition have all been advanced as characteristics of "primary" jobs in center firms. Dualism at the organizational level would be supported if such job attributes differentiate firms into core and periphery locations.[17] The relative importance of each job attribute in discriminating firms would assist in evaluating various perspectives on work organization and economic dualism which, as we have seen, accord differential emphasis to specific aspects of jobs.

Institutional economists (Averitt, 1968; Doeringer and Piore, 1971; Williamson, 1975) have argued that "markets" and "hierarchies" are two different "rational" responses to the problem of organizing production; large firms have greater incentive to internalize the market through organizational rules and procedures, while similar arrangements are of

---

[16] Such configurations could be obtained using a number of descriptive multivariate statistical techniques, such as discriminant and cluster analysis; for some detailed illustrations, see Bielby and Baron (1979).

[17] Since the correspondence between core/periphery sectors and primary/secondary labor markets is far from perfect, one might find a "deviant" cluster of firms containing *both* primary and secondary production. jobs.

limited utility within small firms. If so, then this should be clearly reflected in the pattern of such results on the extent of dualism or segmentation, the crucial level(s) of analysis at which it prevails, and the dimensions of sectoral structure. Failure to detect cleavages at the industry and firm level of analysis would certainly discredit segmentation accounts. Of course, evidence of dualism or segmentation is not necessarily inconsistent with a neoclassical economic model incorporating imperfect competition and the costs of information and firm-specific training. But, unless sectoral differentiation corresponds to industry differences in capital concentration and composition, it is unclear how other patterns of "clustering" could be accounted for within a neoclassical framework.

The Impact of Dualism: Sectoral Location and the Firm's Internal Job Structure

In a recent review of directions in stratification studies, Udy (1980:157) notes how early researchers' focus on occupations and status "did not require [them] to penetrate organizations, observe the tasks and constraints of the immediate job, [or] the degree of authority and control it conveys. . . ." Despite their avowed concerns with these very phenomena, the new structuralists have done little to redress these glaring omissions. Naturally, we would not expect the analyses outlined in the previous section to reveal a crystal-clear portrait of the dual (or segmented) economy; indeed, a good deal of prior research cautions against such an expectation (Freedman, 1976; Kaufman et al., 1980; Wallace and Kalleberg, forthcoming). However, anticipating at least *some* evidence of economic segmentation, the most obvious question to be examined in turn is: what are the empirical consequences of sectoral differentiation for work arrangements within firms?

As noted above, a major dispute among rival theories of economic organization concerns "the complicated relationships among *technology, jobs, and people*" and changes in those relations over time (Gordon, 1972:89, his emphasis). In the remainder of this subsection, we suggest some illustrative analyses of those relationships and how they differ across sectors. Then we consider how historical changes in such relations can be studied.

An illustration: We focus on relationships between sectoral location and three critical dimensions of the internal job structure of firms—their internal *task differentiation* or division of labor, their *internal labor markets* or promotion ladders, and their *control mechanisms* or supervision hierarchies.

Table 3 presents the hypothesized net relationships between each of twelve firm attributes and these three dimensions of the firm's nonadministrative job structure.[18] Some of these hypotheses have been drawn directly from dualist and organizational perspectives, while others reflect our interpretations of how those accounts view technology and social control in relation to work arrangements. As our discussion throughout should indicate, we think certain of these hypotheses (e.g., the correspondence between sectoral location and the structure of internal labor markets) are either incorrect or drastically overstated. Nonetheless, we regard Table 3 as a "fair" characterization of what dualist, segmentation, and organizational perspectives imply about the determinants of task differentiation, promotion hierarchies, and control mechanisms. Notice that a majority of relationships are hypothesized to differ between center and periphery firms. A fairly stringent test of a generalized dualism hypothesis would be provided by evaluating these differences in firms with unambiguous sectoral locations. Space limitations obviously preclude reviewing and substantiating each of the 69 hypothesized relationships in Table 3, so an overview of the more important ones must suffice.

---

[18] We focus on nonadministrative (i.e., production) jobs for two reasons. Most importantly, organizational research has repeatedly demonstrated that technological and administrative forces exercise their influence most conspicuously at and around the workflow (e.g., Hickson et al., 1969; Grimes and Klein, 1973; Van de Ven and Delbecq, 1974). Additionally, these illustrations were selected from our own research, which utilizes data pertaining primarily to industry-specific (i.e., production-oriented) jobs (see Bielby and Baron, 1979).

Table 3. Hypothesized Relationships between Firm Attributes and the Structure of Nonadministrative Jobs within Firms

	Dimension of Internal Structure					
	Task Differentiation		Internal Labor Market		Levels of Supervision	
Firm Attribute	Center	Periphery	Center	Periphery	Center	Periphery
1. Task Complexity	++	++[a]	++	0	++	+
2. Skill Level	++	0	+	0	–	0
3. Skill Dispersion	++	0	+	0	+	+
4. Skill Specificity	++	+[a]	++	0	+	0
5. Scale	++	+	++	0	++	+
6. Sex Composition (% female)	–	––	––	––	–	––
7. Craft Union	++	+	++	+	+	0
8. Industrial Union	–	––	++	+	?	?
9. Production Continuity	++[b]	+[b]	?	0	inverted U	inverted U
10. Capital Intensity	++	+	+	0	+[c]	+[c]
11. Age of Establishment	0	0	+	0	0	0
12. Sector Main Effect	+	–	+	–	+	–

Net Relationships: Strong positive (negative) relationship: ++ (––)
Moderate positive (negative) relationship: + (–)
No relationship: 0
No hypothesis: ?

Notes:

[a] Much less variation is expected in the periphery; therefore the standardized effect should be much weaker in periphery firms.

[b] Perhaps inverted U.

[c] Increasing at a decreasing rate.

Also, the table does not present hypotheses relating outcome variables to interactions among firm attributes, even though they might be defensible on theoretical grounds.[19]

Task differentiation—the subdivision of work into a number of component jobs—may be a consequence of technical or control imperatives. The *technical* division of labor simply reflects the efficiency of task specialization, but differentiation as a strategy of domination should control the work force through fragmentation in bureaucratically organized firms, while "simple hierarchy" is more easily exercised over a homogeneous work force (Child, 1973; Edwards, 1975; 1979). The hypothesized positive relationships between differentiation and complexity, skill, scale, and technology variables among center firms reflect the operation of the technical imperative, which is reinforced by a tendency for technical and bureaucratic control strategies to accompany specialization. In the periphery, however, simple hierarchy (in which power is still personal rather than systematized within roles) should be the more prevalent mode of dominance, and the strategic effort to homogenize work should attenuate the effects of the technical variables (Edwards, 1979).

Efforts to deskill and homogenize work often produce (or take advantage of) an increasingly larger proportion of female workers, and such efforts should be most typical of periphery firms (Davies and Reich, 1972; Braverman, 1974). It is in the interest of craft unions to maintain skill hierarchies and detailed job descriptions, while industrial unions are more likely to mobilize an undifferentiated work force (Aronowitz, 1973). Therefore, the strategy of craft unions should be congruent with the prevailing technical and control imperatives in center firms, while the opposite should be true of industrial unions. On the other hand, core/periphery typologies often construct sectors by combining industries in which craft *and* industrial unions predominate. For example, construction and mining are both regarded as core industries, while printing and garment manufacture are often assigned to the periphery. Indeed, firms within certain industries (e.g., metal trades) are often organized by either or both types of unions. Thus, it is quite possible that these hypotheses pertaining to the impact of unions would not be supported in analyses utilizing industrial classifications of economic sectors.

---

[19] For example, among center firms the ability of unions to implement internal labor markets may be contingent upon such factors as skill specificity, capital intensity, and age of the establishment (Doeringer and Piore, 1971). Moreover, technical constraints such as scale and production continuity may attenuate or accelerate the efficacy of control strategies (and vice versa). While such hypotheses have not escaped our attention, elaborating them here would complicate matters unnecessarily.

Internal labor markets are ideally suited to the bureaucratic mode of social control: they institutionalize and reduce conflict between management and labor; instill long-term commitment to the firm and reduce labor turnover among employees; and reinforce workers' interests in existing administrative arrangements. Therefore, according to dualist theory, internal labor markets should be virtually absent in periphery establishments, and particularly prevalent in large-scale, unionized, center firms where tasks are complex and skills are sophisticated, diverse, and firm-specific.

The number of levels of supervision among nonadministrative jobs is an indirect measure of bureaucratic social control (Child, 1973). Firms organized according to simple hierarchy have fewer levels of supervision between top management and the workflow. In contrast, bureaucratically organized firms have decentralized decision-making apparatuses which are likely to be reflected in multilevel supervision hierarchies (Stinchcombe, 1959).[20] Technical considerations such as the scale and complexity of operations are also likely to effect a proliferation of supervisory levels (Perrow, 1967; Blau and Schoenherr, 1971), although in periphery firms simple hierarchy is likely to attenuate trends toward vertical differentiation. For both sectors, we hypothesize the well-documented curvilinear relationship between production continuity and the expansion of supervisory levels (e.g., Blau and Schoenherr, 1971; Blau et al., 1976).

A crucial aspect of firm structure is left unexamined by such interfirm comparisons—namely, how jobs are connected relationally within an establishment. For example, the contours of supervision and promotion hierarchies among the production jobs within a firm—and their relation to such attributes as skill level, closeness of supervision, demographic composition, and on-the-job training—might be examined by applying any of a variety of sociometric techniques (e.g., Hubert and Baker, 1978) to data describing positional networks within a firm (cf. Moch, 1979). Dualist and segmentation accounts would suggest that center firms, in which internal ladders and bureaucratic control supposedly predominate, are likely to recruit production-level supervisors from within the establishment and to tie hierarchies of promotion and supervision to gradients of skill and firm-specific experience. Periphery enterprises, on the other hand, purportedly lack internal ladders of authority and career advancement, and are more likely to utilize simple hierarchy as a mode of dominance. Thus, networks of power and promotion should less faithfully reflect gradients of skill and training in the periphery.

A note on differences in work organization within sectors: Such a focus on the sociometry of jobs would certainly inform debates about sectoral variation in work organization. Moreover, it would also reveal how analyses of industrial segmentation obscure important differences in job arrangements from firm to firm. To illustrate this claim, we have constructed matrices which show the promotion and supervision links among production jobs for two chemical establishments contained in our sample of California firms (Figures 1a and 1b). In addition, the figures list the general educational development (GED) and specific vocational preparation (SVP) required for each job, and indicate whether the job is characterized by situations in which adaptability to vari-

---

[20] Edwards (1979) distinguishes "technical control" as an intermediate evolutionary form in the transition from simple hierarchy to bureaucratic control. This suggests a continuum of organizational control (rather than discrete categories) ranging from centralized and personalized to decentralized and systematized (also see Blauner, 1964).

Figure 1b. Promotion and Supervision Links among Production Jobs in Chemical Plant "B" (see text for explanation).

ety and change are important (VARCH), in which tasks are repetitive or continuous (REPCON), in which responsibility for the direction, control, or planning of an activity is required (DCP), and in which the precise attainment of set limits, tolerances, or standards is necessary (STS). The physical demands (low, medium, or high) of the job are also listed.[21] It should be underscored that these data pertain to typical "job-worker situations" which prevail within the establishment. They thus combine official policies of the enterprise with the analyst's observations of what actually has transpired vis-à-vis specific jobs (and their incumbents) in a firm.

---

[21] VARCH, REPCON, DCP, and STS are dummy variables with "1" indicating the presence of each temperament. For more information about data collection methods, definition of concepts, and measurement of these variables, see United States Department of Labor (1972). Production jobs which were not specific to this industry—and thus were not analyzed in detail by the Employment Service—are indicated in Figures 1a and 1b by an asterisk. Ratings for those jobs have been taken from published and unpublished data prepared for the third edition of the *Dictionary of Occupational Titles*.

Figure 1a pertains to firm "A," a chemical plant involved in processing and purifying fatty acids. The parent corporation, now multinational, was founded in 1840, but this plant was established after World War II. The firm has 161 employees (of which 105 are involved in production), is unionized, and operates four shifts at two production sites located five miles apart. Fatty acids produced in one department ("P2" in Figure 1a) are the chief constituent of organic chemicals produced by the other ("P1"). All workers enter as laborers, and advance by a union bidding arrangement based on seniority rights.

The letter "P" in the matrix indicates that the job listed in that row can *promote* to the job listed in the relevant column. An "S" indicates that the row job *supervises* the column job. Figure 1a corresponds rather nicely to simplified conceptions of dual economy which characterize the chemical industry as belonging to the core, manifesting internal ladders of promotion based on skill and seniority. Like the chemical plant studied by Blauner (1964), firm "A" is organized departmentally, with rigid promotion ladders within each of its two production units (i.e., P1–1 through P1–6 vs P2–1 through P2–11). With the exception of laborers in the first productive unit, each job within a department is supervised by the foreman, indicating one level of administration per department. Foremen, in turn, report to the production superintendent (M1). These hierarchies faithfully reflect differentials among jobs with respect to educational and technical requirements (GED and SVP). In each department, only the foreman job is characterized by "variety and change" or "direction, control, and planning"; jobs toward the bottom of the promotion and supervision ladders are "repetitive and continuous." Adherence to predetermined tolerances or standards is important for all jobs except those at the bottom and the top of each department's hierarchy. Ladders of promotion and authority also correspond rather closely to the physical demands of work, with those at the bottom performing the most strenuous tasks.

Figure 1b presents comparable data for chemical firm "B." This establishment is in exactly the same four digit S. I. C. classification as firm "A," and of almost identical size (173 employees, of which 83 are engaged in production). Its administrative and operating procedures also seem to be virtually identical to those of firm "A": establishment "B" operates four shifts, is also part of a larger corporation, and is divided administratively into five departments (versus six for firm "A").

However, the authority hierarchy and the structure of opportunity implied by the promotion network are conspicuously different from those shown in Figure 1a. (Since the promotion ladder in firm "B" is especially difficult to decipher from Figure 1b—that is, one cannot permute the rows to obtain a systematic pattern of promotion—we have also expressed it graphically in Figure 1c.) Note that laborers (P15), for example, can be promoted directly to leadmen; indeed, union agreements stipulate that *only* laborers can be promoted to leadmen. (Laborers are also promoted into *five* other positions. Prevailing union practices allow laborers to bid for any position; however, the detailed job analyses indicate that laborers actually *do* move up as indicated in Figure 1c.) Leadmen, in turn, can move into supervisory positions, while dust plant operator (which requires greater educational and vocational training) is a "dead-end" job. Leadmen also supervise solution operators, even though the latter job again requires more educational and vocational preparation. A lift truck operator can promote to flaker operator, even though the latter job requires less training time (SVP).

In short, promotion and supervision hierarchies are considerably less orderly in this establishment. Entry level incumbents can in principle bypass certain "dead-end" jobs between the bottom and top of the departmental hierarchy. Moreover, gradients of skill and experience bear less relation to the structure of opportunity and authority. (There is also much less correspondence between levels of promotion and supervision on the one hand, and temperaments and physical

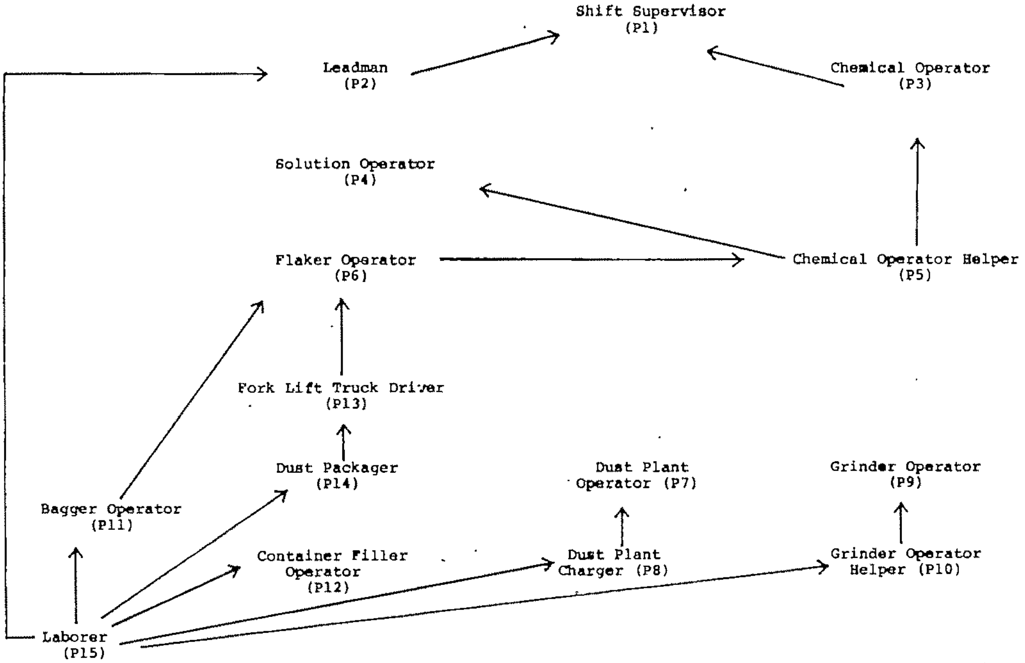

Figure 1c. Promotion Ladder within Chemical Firm "B" (adapted from Figure 1b; arrow[s] indicate job to which promoted).

demands of jobs on the other, at least compared to establishment "A.") Both chemical firms are represented by the same union, are located in the same state and detailed industry category, and, indeed, were analyzed by the same individual at the same point in time. Thus, any persuasive explanation of why these two establishments organize work roles so differently must move beyond simple, mechanistic notions of "dualism" or "segmentation," focusing on the concrete organizational and suborganizational determinants of promotion and supervision.[22] Of course, this is not to suggest that industrial distinctions are irrelevant, or that hypotheses inspired by dualist or segmentation approaches would not be helpful in distinguishing these establishments from those in some other industry.[23] However, as Burawoy (1979:245–6) notes,

> the distinction between competitive and monopoly sectors can explain only so much of the variation in the labor process. Differences within each sector are probably as great if not greater than differences between sectors.

---

[22] One conspicuous difference between the establishments involves the physical separation of departmental units in firm "A" but not in "B." This factor might explain, for example, the existence of two nonproduction jobs—shipping clerk and truck driver—within the organic chemicals department of firm "A." Presumably, these jobs involve transferring fatty acids from the other production site. However, another anomaly is apparently unrelated to this difference between establishments. While firm "A" employs its stock clerk in the maintenance department, the same nonproduction job is situated within the production unit of firm "B." The psychological and economic significance of work-unit location and structure has been documented in the chemical industry (Blauner, 1964; Gallie, 1978) and in economic organizations generally (e.g., Grimes and Klein, 1973; Van de Ven and Delbecq, 1974; Comstock and Scott, 1977). Thus, such differences in work organization among firms—which cannot be explained by simplistic theories of segmentation—are likely to have important effects on worker experiences.

[23] Indeed, network data of this type would be quite useful in examining such hypotheses. Normalized measures of "fit" between hierarchies of supervision, promotion, skill, training, and other job attributes can be computed for each firm (see, for example, Hubert, 1978). Such measures may then be employed as firm-level characteristics with which to test whether internal job structures do in fact differ across sectors.

The Trend in Dualism: Temporal Changes in Enterprise Work Organization

We suggested earlier in this essay that historical transformations in work organization—while central to disputes among students of inequality—have been largely ignored by researchers. The few empirical studies undertaken (e.g., Horowitz and Herrnstadt, 1966; Scoville, 1969; Dubnoff, 1978; Spenner, 1979) have done little to advance the debate, since differences among perspectives primarily concern how changes in work arrangements are instigated and implemented *within the firm*. Furthermore, most analyses have failed to consider rival explanations for the patterns of change documented.

An illustration: One could compare various structuralist perspectives against a neoclassically inspired alternative by studying temporal changes in numerous firm-level phenomena—for example: in the number of distinct jobs within the enterprise; the number of employees (by sex, race, etc.); degree of administrative intensity; or the overall level and degree of homogeneity of skill among jobs. For expository purposes, we select one of these—changes in the firm's "skill mix"—and outline analyses for manufacturing establishments.

According to neoclassical theory, changes in the quantity and quality of labor utilized should reflect the calculus of marginal substitution whereby factor inputs are employed until their marginal productivity and cost are equal. Assume, for the moment, that the firm is in perfectly competitive commodity and labor markets and that it experiences constant returns to scale; furthermore, we allow all factor inputs to be variable over the interval under study. Under these conditions, the mix of labor and capital (and of various types of labor) employed, far from reflecting any control imperative or the like, should be

> determined by purely technical properties of the production function relating the quantities of these inputs used and their respective marginal physical products. If we knew the exact form of the production function, we could predict the behavior of the factoral shares (Nicholson, 1978:419).

Thus, if perfect competition prevails, one could examine temporal changes in industrial capital expenditure and the prevailing wages paid to different classes of workers (grouped according to skill) on the one hand, and the value added by capital and labor on the other hand, in order to determine if this simplified base-line model "makes sense." In other words, one would follow neoclassical precedent by first assuming that firm decisions are derivatives of industrial conditions over which the perfectly competitive enterprise has no control.

Briefly stated, to the extent that this naive neoclassical model is accurate, changes in absolute and relative employment among various skill families should correspond to patterns of change in productivity and factor prices for the industry within which the firm produces.[24] Clearly, this model will fail to explain firm-specific changes in skill composition in many instances. This failure may only reflect the dubiety of assuming perfect competition or constant returns to scale. Thus, one would next conduct "deviant case" analyses to determine whether departures from this simplistic neoclassical scenario can be subsumed under more complex and realistic assumptions concurrent with neoclassical orthodoxy. For example, the types of data usually employed in studies of industrial segmentation index the structure of input and output markets, allowing an assessment of whether firm "deviance" is simply attributable to location within an industry which departs from perfect competition. Conditions of industrial instability—tapped by such variables as work stoppages—may also account for patterns of skill utilization not predicted by the base-line model, either because the specification of the production function is inappropriate for such industries, or because of the effect of uncertainty on administrative decision making. If, as radical theorists suggest, owners and managers typically respond to such uncertainty by fragmenting, deskilling, or homogenizing their work force, then firms should institute such changes in their skill mix even when "market forces" imply drastically different "rational" responses.

---

[24] Since the enterprise is assumed to be in perfect competition, published industry-level data (e.g., in the *Census of Manufactures*) documenting costs and productivities of classes of labor and other factor inputs should characterize the economic and technical constraints which guide the firm's decisions regarding productive arrangements.

In sum, we envision a dispersion of firms around predicted changes in skill distributions based on a simple version of the neoclassical model. Indeed, segmentation theorists often grant the decisiveness of market forces within the periphery, and, thus, these naive predictions should depict patterns of change most accurately for firms located there. If critics of neoclassical orthodoxy are correct, the most drastic outliers should consist of center firms so insulated from market mechanisms that even the most generous variants of neoclassical theory cannot account for their behavior.

SUMMARY AND CONCLUSIONS

This essay has examined the recent shift toward more structural explanations in studies of inequality. After providing a brief overview of this body of research and some of its shortcomings, we examined its theoretical underpinnings, comparing structuralist perspectives on work organization derived from institutional economics and neo-Marxism to more orthodox accounts based on neoclassical and industrialism theories. This discussion, coupled with an examination of the levels and units of analysis adopted by various approaches, suggested areas where the different perspectives overlap and diverge. We concluded that social scientists interested in the structure of social inequality would benefit immeasurably by "bringing the firms back in"—that is, by incorporating organizational structure and process into empirical analyses of economic segmentation and work. Work arrangements within firms (and their trend) are the focus of most structural perspectives on positional stratification; thus, empirical studies grounded at the organizational level are more likely to inform current debates about the structure of work than is the growing body of research about structural effects on individual attainment or covariation among occupational and industrial characteristics.

Structuralists typically dismiss status attainment research by arguing that models of the socioeconomic career are misspecified unless they embrace the structures which organize attainment (e.g., Sørenson, 1975; Bowles and Gintis, 1976; Burawoy, 1977; Wright and Perrone, 1977; Beck et al., 1978; Stolzenberg, 1978). However, "structures," too, are not immune from misspecification. Unlike research on the person-level determinants of achievement, the new structuralism is not leading toward a cohesive set of findings, perhaps because structures have been either assumed or inferred from their consequences for individuals, rather than subjected to detailed empirical scrutiny. In an effort to correct that deficiency, we outlined an agenda for future research, focusing on three aspects of work organization: (a) the units which comprise the structure of work and the dimensions underlying economic segmentation; (b) the effects of sectoral differentiation on technical and administrative arrangements within the firm; and (c) temporal changes in how enterprises organize production. While data sources at the job or firm level are admittedly scarce, they do exist; each of the analyses outlined here is part of our own ongoing program of empirical research utilizing data collected by the United States Employment Service (Bielby and Baron, 1979; 1980).

We fully expect that more complete data on jobs, firms, and industries will be assembled by social scientists as they become increasingly fond of structural perspectives on social stratification. However, we think careful consideration of this new orientation—its underpinnings, strengths, weaknesses, and implications—is timely, before the emerging consensus about the importance of "structure" assumes the status of dogma and engenders a conditioned response among researchers to construct categorical variables.

Underlying our discussion is the conviction that the first step among structural stratification researchers must be to specify a theory of the relevant structure(s), and provide empirical referents which allow the veracity of that theory to be tested. To the extent that the various perspectives employed in structural research are scientifically useful, they must possess empirical content; as a consequence, the choice among them requires analyses which subject predictions of competing accounts to the possibility of meaningful empirical falsification. In our view, this aim is best accomplished neither by simply imposing (or justifying) a particular structure by fiat, nor by inferring it post hoc from its effects on the micro elements over which it is assumed to be logically and temporally prior. Rather, one must examine its constituent elements and the ways in which they are organized. Yet much of the recent structuralist achievement research either adopts a specific perspective (e.g., Marxism) to rationalize a model of attainment, or else assigns priority to the attainment model and justifies the importation of one or more substantive frameworks (e.g., dual economy theory, organizational sociology). In our view, issues of individual socioeconomic attainment should not detract attention from more fundamental questions regarding the characteristics of those structures which (presumably) shape achievement. By relating studies of segmentation and stratification more directly to the organization of work within firms, we hope to strengthen the correspondence between theory and method among those studying either the "empty places" in our economy or the people who occupy them.

CRIME AND POVERTY: SOME EXPERIMENTAL EVIDENCE FROM EX-OFFENDERS

RICHARD A. BERK

KENNETH J. LENIHAN
John Jay College
City University of New York

PETER H. ROSSI
University of Massachusetts at Amherst

American Sociological Review 1980, Vol. 45 (October):766–786

Building on perspectives from sociology, criminology, and economics, this article reports findings from a randomized experiment undertaken with over 2,000 ex-offenders in the states of Texas and Georgia in which unemployment benefits were extended to individuals immediately upon release from prison. The analysis focuses on the endogenous relationships (over a one-year follow-up period) between these "transfer payments," unemployment, arrests for property and nonproperty crimes, and the resulting time spent in jail or prison. By and large, the hypotheses derived from a priori theory are supported by the data.

INTRODUCTION

Strong individual and aggregate level correlations between poverty and official measures of crime are perhaps among the most firmly established of social science empirical generalizations. However calculated, official crime rates are almost always higher among the poor, and poor people are more likely to be arrested and convicted for a wide variety of offenses. Yet, the precise mechanisms linking poverty to crime remain elusive. Writers as diverse in their perspectives as William A. Bonger (1916), Robert K. Merton (1957) and Gary S. Becker (1968) have provided plausible theoretical explanations, but, to date, the empirical tests have proved equivocal.

Part of the difficulty no doubt stems from conceptual ambiguities: should economic need, for example, be treated as an attribute of an individual (e.g., Ehrlich, 1973), or as an attribute of some social entity (e.g., Miller, 1958)? Problems in measuring the "real" rate of crime (Erikson and Empey, 1963; Sparks et al., 1977; Penick and Owens, 1976) and in making proper causal inferences from aggregate data (Blumstein et al., 1978; Brier and Fienberg, 1980) further complicate matters. However, perhaps the major obstacle has been the necessity of relying on naturally occurring variation in critical exogenous variables.[1]

First, there is no guarantee that the exogenous variables of particular interest

---

The research reported in this paper required the active cooperation of a large number of people. We are enormously indebted to the research staff put together under the auspices of the prison systems of Texas and Georgia; to research assistants Anthony Shih, Nancy Jurik, Jeffrey Liker, Eleanor Weber-Burdin, and J. Patrick Henry; and, especially, to Dr. Howard Rosen, formerly of the Department of Labor's Employment and Training Administration. The research was supported by DOL Grant No. 21-25-77-05, "Analysis of Transitional Aid Research Project (TARP) Experimental Data," of which Rossi was Principal Investigator. A full exposition of the TARP experiments and the findings is to be found in Rossi et al., 1980. The authors are listed in alphabetical order to denote equal authorship.

[1] Possibly the strongest empirical case for disentangling the relationships between poverty and crime through the observation of naturally occurring variation can be built from time-series analyses in which economic indicators (with appropriate lags) are related to indices of crime over time (Brenner, 1976). Although such studies have shown that various crime indices are indeed sensitive to lagged unemployment rates and other economic indicators, the level of aggregation in such analyses has been countries as a whole or large jurisdictions within countries, a level far removed from individuals. Thus, one risks the ecological fallacy if inferences to individuals are made.

will possess sufficient variance to permit powerful tests of causal hypotheses. At the extreme, some variables may approximate constants. Second, when sufficient variance does exist, collinearity among the exogenous variables can effectively prohibit the estimation of stable multivariate models. At the extreme, the matrix of regressors may be singular. Finally, even with the aid of recent advances in structural equation modeling, the direction of causal effects can be extremely difficult to disentangle. At the extreme, a set of simultaneous equations may be hopelessly underidentified so that unique parameter estimates cannot be calculated.

Consider the following alternative: suppose it were possible to manipulate at least some of the important causal variables in a manner that would generate the desired variation, that would reduce and perhaps eliminate multicollinearity, and that would permit one to determine whether change in a prospective causal variable in fact preceded change in an outcome of interest. This model, of course, comes from experiments undertaken in laboratories and, of late, has been increasingly applied in field settings. Indeed, the randomized experiment, probably the definitive laboratory research design, has been used in well over 300 natural settings within evaluation research traditions alone (Boruch et al., 1978).

The prospect of experimental manipulation suggests a number of possibilities for the study of poverty and crime. In particular, while it would clearly be cruel and capricious to randomly impoverish persons or households in service of social science rigor, it is at least not cruel to randomly provide supplemental income to poor persons or households in order to determine if such changes in resources have important behavioral consequences.

In this article we will present evidence on the relationship between poverty and crime gathered from two randomized experiments, each conducted with samples of close to 2,000 persons who were released over a 6-month period in 1976 from the state prisons of Georgia and Texas. Under the name of the Transitional Aid Research Project (TARP), persons released from the prisons were assigned either to one of four treatment conditions or to one of two control groups. The treatments provided either eligibility for unemployment benefits at several levels or the alternative of job counseling. One of the two control groups was followed in detail while the other was followed only through administrative records.[2]

In the analysis reported here, we will pay particular attention to the impact of the TARP experimental treatments on arrests (proxies for participation in crime) over a 12-month period following release from prison. These treatments, in effect, substantially changed many ex-felons' income prospects, and the primary goal of TARP was to determine whether or not these efforts to reduce economic hardship in the period immediately after release from prison lowered participation in crime and, therefore, the likelihood of arrest.

Are ex-felons an appropriate group for the study of the relationship between poverty and crime? On the negative side, one might argue that they constitute so self-selected a portion of some broader population that any findings would be difficult to generalize. After all, they have presumably engaged to a greater or lesser degree in a "life of crime": that is, officially at least, why they were sent to prison. On the positive side, it can be argued that since these are persons who have already on previous occasions opted for illegal activities, a test of the effect of poverty on crime may be especially strong. If the provision of income to individuals with clear "criminal proclivities" can reduce participation in illegal activities, then the difference made in income would be especially compelling. We believe that ex-felons are a fully appropriate population to study and, in the pages to follow, will provide theory and data to show support of this view.

BACKGROUND OF THE TARP EXPERIMENT

A host of obstacles face ex-felons upon their release from prison (Lenihan, 1977; Irwin, 1970). These obstacles take a number of forms, and among the most formidable is extreme financial hardship. "Gate money" provided by the state is rarely sufficient for more than a few days of subsistence, accumulated earnings from prison work are usually little more than loose change, and eligibility for welfare or other transfer payments is almost nonexistent for the unmarried young man in his twenties who is the typical released prisoner.

---

[2] Greater detail on the treatment and control groups will be provided later in this article.

Employment prospects are equally grim. Few prisoners have attractive work histories, having spent very large proportions of their adult lives in prison. Correspondingly, they have few marketable skills, "human capital" or contacts that would facilitate the job search process. Moreover, the stigma of a criminal record hampers efforts to find legitimate employment. Indeed, given their lengthy day-to-day involvement with other criminals in prison and their record of previous criminal activity, a rational course of action might well lead directly to renewed participation in illegal activities (Becker, 1968; Ehrlich, 1973; Block and Heineke, 1975).

With these realities in mind, the beginnings of the TARP experiments can be found in the Manpower Development and Training Act of 1962 (and subsequent amendments) which gave to the Department of Labor a mandate to devise and provide programs responding to the employment needs of ex-prisoners. The Department initially launched manpower training projects within prisons and after release. Unfortunately, evaluations of these efforts found little evidence of success. The Department then turned to testing short-term, income-support strategies for the period immediately after release from prison. The first experimental program consisted of two kinds of interventions: special job placement and counseling for ex-prisoners, and eligibility for short-term transfer payments similar to unemployment insurance benefits[3] (Lenihan, 1977; Mallar and Thornton, 1978; Rossi et al., 1980). In the first instance, special placement and counseling services were thought to speed an ex-offender's reentry into the labor force and, consequently, reduce participation in criminal activities. In the second instance, modest transfer payments of about $60 a week for periods of up to 13 weeks (for those who could not find jobs) were thought to subsidize the job-search process and, in addition, to reduce the need to resort to crime as an alternative source of income.

After some initial pilot testing, the two interventions were field-tested in a randomized experiment conducted in Baltimore. Known as the LIFE experiment, approximately 400 men about to be released from state prisons were randomly assigned to either one treatment, both treatments, or neither treatment (thus, three experimental groups and one control group in a fully crossed design). Exprisoners were then followed for up to two years in order to gauge immediate and longer-term effects. The placement and counseling intervention apparently had no impact on re-arrests, but the payments-eligibility intervention reduced re-arrests for property crimes about 8% (the difference between the two groups eligible for payments and the two groups that were not eligible). While the reduction was statistically significant and encouraging, it was hardly definitive (Lenihan, 1977; Mallar and Thornton, 1978).

In order to better document the apparent success of the LIFE experiment and explore the mechanisms by which the reduction in re-arrests occurred, the TARP experiment was launched. Approximately 2,000 men and women in each of the states of Texas and Georgia who were about to be released from state prison were randomly assigned to four treatment groups and two control groups based loosely on the treatments delivered in the LIFE experiment.[4]

Table 1 shows that the three payment groups varied along two important dimen-

---

[3] Given the usual eligibility rules based on employment for the preceding five quarters (or so), most ex-prisoners are automatically excluded from unemployment payments even if they had been working immediately prior to their incarceration.

[4] As the second control group was not interviewed during the postrelease year but only followed through administrative records, no information is available on employment for this group. Hence, it is not considered in this analysis.

Table 1. Target and Actual Number of Persons in TARP Groups Achieved at End of Recruitment

TARP Group	Target No. in Each State	Actual No. in Georgia	Actual No. in Texas
Group 1: 26 weeks of payments, 100% tax	175	176	175
Group 2: 13 weeks of payments, 100% tax	200	199	200
Group 3: 13 weeks of payments, 25% tax	200	199	200
Group 4: job placement only	200	201	200
Group 5: interviewed controls	200	201	200
Total	975	976	975
Group 6: noninterviewed controls[a]			

[a] Randomly selected controls, whose postrelease behavior was monitored only through administrative records—e.g., state criminal justice computerized arrest records and unemployment insurance wage files. See fn. 4.

sions: the maximum number of weeks for which unemployment benefits would be provided and the tax on earnings from legitimate employment. Thus, ex-prisoners could obtain up to either 13 or 26 weeks of support, and their payments would be reduced either dollar for dollar (100% tax) or 25¢ on the dollar (25% tax). Georgia participants were eligible for payments of $70 a week and, for the 100% tax groups, forgiveness amounts of $13.75 (i.e., the first $13.75 of earnings had no impact on unemployment payments). Texas participants were eligible for $63 a week and, for the 100% tax groups, forgiveness amounts of $8.00. The job-placement treatment consisted of special counseling efforts and grants of up to $100 for the purchase of tools, special work clothes, and other work-related expenses. Finally, Table 1 indicates that, with a few trivial exceptions, the recruitment process in each state produced the desired number of participants in each of the groups. There was also no evidence that the assignment process was other than random.

To anticipate some important issues that will surface later, the TARP treatments differed in at least three important ways from the earlier Baltimore LIFE treatments. First, planned variation in weeks of eligibility was introduced into the TARP experiments in order to better determine the relative cost-effectiveness of different levels of support. If the experiments were successful in reducing rearrest rates, the question of cost would certainly rise to the top of the political agenda. Thus, some effort was made to see how sensitive the effects would be to variations on the number of weeks for which support was provided. Second, similar arguments were used to justify taxing earnings—and taxing them at two different rates. This is in marked contrast to the LIFE experiment in which there was, in effect, little or no tax on earnings. Finally, the LIFE experiment was administered on a day-to-day basis by a research staff under the direction of Kenneth J. Lenihan, while the TARP experiment was administered on a day-to-day basis by the staff of state employment offices, an alteration in administrative procedures that followed from a desire to "field-test" the treatment under conditions that likely would obtain should a TARP-like program eventually be adopted. Thus, in the LIFE experiment, ex-prisoners were in contact almost day-to-day with a research staff whose energies were devoted solely to the experiment, while ex-prisoners in the TARP experiments were in contact on a less-frequent basis with regular public servants who had a range of duties.

Data on the randomly assigned TARP subjects came from several different sources. Prison records were extracted for biographical material predating participation in the TARP experiment, criminal justice records were used to obtain an "official" reading on postrelease law violations, and unemployment insurance files were used to obtain data on earnings subject to unemployment insurance taxes. In addition, TARP subjects in groups 1 through 5 were interviewed immediately prior to release and, then, 3 months, 6 months, and 12 months after release. These interviews covered a host of postincarceration experiences including employment, marital status, living arrangements, major illnesses and accidents, consumer purchases, and the like. Eventually, all four data sources were merged into a single record for each TARP participant addressing the first 12 months after release from prison.

Despite the fact that each of the states organized its own data-collection activities, recruiting and training an ad hoc interviewing staff, high completion rates were experienced; the lowest completion rate for any wave of interviewing was 84%. While measurement left something to be desired in each state, internal evidence indicated that the main policy variables—employment, arrests, and experimental payments—were fairly well measured (see Rossi et al., 1980).

THEORETICAL ISSUES AND MODEL SPECIFICATION

The empirical world rarely comes organized into neat cubbyholes of sociological phenomena, economic phenomena, psychological phenomena and the like. Moreover, it would be hard to argue that any particular social science discipline has had outstanding success in explaining criminal behavior, particularly with respect to the relationship between poverty and crime. Consequently, the theoretical underpinnings for our model specifications will be eclectic, borrowing most heavily from criminology, sociology, and economics.

It is, however, important to understand from the outset that the backgrounds of TARP participants rule out a priori the application of many popular perspectives on crime. In effect, a number of exogenous factors cited by earlier researchers are for all practical purposees held constant. First, all participants in the TARP experiment had just finished at least one year in state prison and most had rather extensive criminal records. In other words, all had shown a considerable talent for getting into trouble with the law. Thus, it is virtually impossible (with this sample) to consider in some fundamental sense why some individuals are arrested while others are not; we are limited to the question of whether past criminal proclivities can be altered. Second, most TARP participants returned to precisely the same environments that presumably had spawned their earlier problems. By and large, they were again exposed to the same mix of family experiences, friendship patterns, economic opportunities, and police practices that had earlier led to their incarceration in a state prison for terms of a year or more. Finally, TARP participants were drawn from the lowest strata of society, having poor educational backgrounds, scant job experience, and meager earnings histories. Few sons and daughters of the middle class were represented.

In short, TARP participants were rather homogeneous with respect to social class, criminogenic background, and exposure to other felons. Moreover, what the TARP experiment is best designed to consider is whether relatively modest changes in an ex-prisoner's economic circumstances affect postprison behavior. These constraints imply the need to focus on the *short-run* interplay between transfer payments, employment, and arrests. Well-known theories resting on such concepts as subcultures, differential association, and blocked legitimate opportunities (see Glaser, 1979, for a recent review) are essentially irrelevant in the sense that variables measuring these concepts are, for TARP participants, effectively constants.

The social science theoretical traditions to which we must turn in order to construct models of the interplay between TARP payments, employment, and crime are to be found primarily in economics and sociology. From the economists we obtain a utilitarian perspective on how choices are made between such things as the alternative sources of income, particularly those of employment and crime. Sociological theory provides us with an understanding of employment variables without monetary equivalents (Heineke, 1978:11–4), including such features as social status, the interpersonal context of employment, and the like.

Utilitarian perspectives on crime rest primarily on the efforts of economists working within neoclassical traditions (e.g., Becker, 1976; Sjoquist, 1973; Ehrlich, 1973; Block and Heineke, 1975; Heineke, 1978) although some sociologists have made contributions (e.g., Letkemann, 1973; Richards et al., 1979). While utilitarian approaches to criminal behavior are quite diverse, the following (Heineke, 1978:1–2) overview captures much of what such perspectives share.

> Economic models of criminal behavior take as given those influences in the personal and social backgrounds of individuals that determine "respect for law," proclivities to violence, preferences for risk and other behavioral characteristics held to be determinants of criminality. These models are based on characteristics of individuals which are alleged to be common not only to large classes of offenders, but to large classes of economic agents in general. In a sentence, the models of economic choice theory, of which the criminal choice is a special case, hypothesize that all individuals, criminals and non-criminal alike, respond to incentives; and if the costs and benefits associated with an action change, the agent's choices are likely to change. More specifically, these models postulate that the decision to commit an illegal act is reached via an egocentric cost-benefit analysis. As is implicit in this statement, the expected benefits and costs associated with an illegal act may contain both monetary and psychic elements. But by treating the individual's "taste for crime" as a datum, one may build a theory of criminal behavior based on the opportunities confronting the potential offender.

Within this broad framework, Heineke (1978) distinguishes two general classes of models: portfolio models and time allocation models. The former address what portion of a decision maker's *wealth* is risked in criminal activity and, therefore, requires that all returns from illegal activity be expressed in monetary equivalents. The latter notes the importance of psychic consequences and the fact that illegal activities are time consuming and, therefore, views participation in illegal activities as, formally, "a labor supply problem with uncertain consequences" (Heineke, 1978:3). For reasons that will soon become apparent, time-allocation approaches are more appropriate for the concerns of this article.

Within the time-allocation perspective, individuals are assumed to face an ongoing set of choices between illegal and legal activities, and individuals will participate in illegal activities as the anticipated returns from illegal actions exceed the anticipated returns from legal actions. Incentives include such things as money, possessions, and excitement, while disincentives include such things as arrests, imprisonment, and guilt. In the usual formal approaches (e.g., Ehrlich, 1973), it is assumed that the returns from illegal activities are uncertain. The uncertainty results from an inability to know in advance whether illegitimate actions will lead to sanctions from the criminal justice system, implying that the costs associated with crime are, in effect, weighted by the probability of experiencing sanctions. For example, if the likelihood of arrest is small, even the most Draconian punishments will have little impact on the anticipated costs of crime.

A critical point often overlooked in more vulgar translations of formal utilitarian approaches is that individual decision making proceeds on a marginalist basis. This means that the *incremental* returns of the next action are compared to the *incremental* costs and that, therefore, it is essential to know the decision maker's circumstances at the point when a decision needs to be made. For example, it is common to assume that each increment in income is worth less to the decision maker than the last (that is, the assumption of diminishing marginal utility); an *additional* $60 a week will mean a lot more to a person earning $100 a week than to a person earning $500 a week.[5]

Given that legal and illegal activities are not completely mutually exclusive, individuals must continually decide what mix of activities is appropriate. Within formal utilitarian approaches, individuals are assumed to select some mix of activities yielding the maximum anticipated returns conditional on such practical constraints as the amount of time and other resources available (that is, budget constraints). For some decision makers this may mean that crime becomes virtually a full-time job; for others this may mean that criminal activities are at most an occasional source of supplemental income. And all manner of combinations in between are fully possible. What matters, then, is the balance of incentives coupled with practical constraints.

---

[5] This also implies that an individual is "risk averse" (Barnett, 1973:105–9). The expected returns from a "gamble" must exceed (somewhat) the value of resources invested—or the gamble will not be taken. We will have more to say about this later.

Given the constraints, the mix of legal and illegal activities producing maximum returns implies that no other mix can yield greater returns, and, when this mix is achieved, individuals are said to be "at the margin." It cannot be overemphasized that the empirical predictions from the formal utilitarian models apply *only at the margin*. Thus, the implications of a change in the probability of sanction, for instance, can be formally assessed only for the mix of activities from which maximum returns are obtained. The predictions do not apply to individuals who, for one reason or another, are not at the margin.

While the formal utilitarian perspectives typically emphasize the role of monetary incentives or incentives with monetary equivalents, there is, nonetheless, some concern for factors that are perhaps of more interest to sociologists. Block and Heineke (1975), for example, "build in" the effects of the psychic consequences of criminal activities. Human-capital theories provide for the possibility that the skills required for both legal and illegal activities can be enhanced through a variety of formal and informal educational processes. (See Rosen, 1977, for a recent review of the human-capital literature.) Becker (1971) and Arrow (1972; 1973), among others, have provided models that can be used to explain, in a not entirely satisfactory fashion, the kinds of discrimination faced by ex-prisoners in the job market. Finally, the job search literature (for a recent review see Lippman and McCall, 1976a; 1976b; 1979) can be applied not only to efforts to find legitimate employment but also to finding illegitimate "employment."

The fact that utilitarian models allow for variation in tastes only as a residual causal variable is, from a sociological point of view, a major flaw. However, a more serious deficiency for our purposes lies in the treatment of legitimate employment almost exclusively as a source of income. The sociological perspective on employment provides a number of additional dimensions. First, being employed at any job is a valued status, as the occupational-prestige studies have shown (e.g., Nock and Rossi, 1978). Studies of the unemployed (Hyman, 1980) have documented the deleterious effects of unemployment on self-esteem and morale. Indeed, an analysis of the social-psychological impact of unemployment among TARP members (Liker, 1980) shows that ex-felons are not immune to the same processes. Second, employment on the usual legitimate job implies being placed in contact with fellow workers, providing an interpersonal environment that may lead to new social circles, exposure to different values concerning the legitimacy of illegal activities, and so on. Finally, the returns from employment often increase with seniority; continued employment increases the stake involved in loss of employment (which economists also claim).

Thus, these briefly outlined theoretical considerations provide the background for the construction of a testable model representing the competitive interplay among work, payments, and crime—all, the endogenous outcomes of primary interest. At the outset, however, it is necessary to deal with a serious measurement issue. While we have been stressing time allocations as a "labor supply" problem, we have no direct measure of time allocated to crime. We are forced, therefore, to rely on the *number* of arrests recorded by the criminal justice system over a 12-month follow-up. We are fully aware of the loose fit between arrests and participation in illegal activity, but—at least from a policy point of view—arrests are a popular measure of recidivism. Moreover, since we are concerned with *changes* in criminal activity in response to the TARP experiment, we are able to tolerate either random measurement error and/or consistent underestimates (or overestimates) when arrests are endogenous.

Two kinds of arrests will be used: arrests for property crimes and arrests for nonproperty crimes.[6] This distinction follows from the desire to distinguish those crimes that most likely have an earnings motive from those crimes not likely to produce income. As a measure of time invested in legal income-producing activities, we will rely on the number of weeks worked during the postrelease year, as reported in follow-up interviews with TARP participants.

---

[6] "Nonproperty" crimes are a heterogeneous class ranging from murder and serious assault to

An additional endogenous variable, jail and prison time, must be added to the original three as it often follows from arrests and, in turn, affects both payments and employment. Clearly, while sitting in jail (usually awaiting arraignment or trial) or in prison, after sentencing, an individual can neither work, engage in the usual criminal activities, nor receive payments.

Finally, the TARP treatment for which randomization was undertaken was *eligibility* for unemployment compensation. And eligibility, by itself, probably has little meaning unless translated into measures of how much money was actually given to TARP participants; it is, presumably, the money, not the eligibility per se, that is important. Consequently, our fifth, and last, endogenous variable is the number of dollars given to TARP participants over the 12-month follow-up.[7]

It should be apparent that a number of causal links are likely to exist among the five endogenous variables. *By design*, payments were reduced by employment and eliminated if the ex-prisoner was incarcerated. Prisoners behind bars could not seek employment and were not subject to additional arrests. Arrests for both property and nonproperty crimes should increase the number of weeks spent in jail or prison. These relationships are shown in Figure 1 along with causal effects that require somewhat more explanation.

First, if one assumes a diminishing marginal utility from income, TARP payments should reduce the time allocated to both employment and income-producing crime. Thus, other things being equal, TARP participants who receive greater amounts of money through TARP should evidence fewer arrests for property crime and fewer weeks worked.

The assumption of a diminishing marginal utility from income is common within the broader framework of neoclassical traditions (e.g., Nicholson, 1978:60–76) and is equivalent in this instance to saying that individuals are risk-averse (Barnett, 1973:105–9). By assuming that ex-prisoners are risk-averse, we are claiming that there is nothing basically unusual about the way they make decisions under uncertainty. However, we must also acknowledge that some economists who study crime resort to alternative assumptions and, in particular, that at least some individuals with criminal proclivities are risk-prone. (For the implications of different assumptions about risk, see Heineke, 1978.) We find such alternative conceptualizations vulnerable to the charge of ad hoc theory construction and prefer to continue with the more general perspective that ex-prisoners allocate their time through mechanisms common in the general population.

Second, TARP payments increase the opportunity-costs of arrest because recipients have more to lose (that is, the TARP payments). Consequently, individuals who receive support through TARP should experience fewer arrests for both property *and* nonproperty crimes.

In "real life," of course, it was not arrests per se but, rather, incarceration that eliminated TARP payments. Moreover, some ex-prisoners no doubt received TARP payments despite brief periods of incarceration, perhaps prior to trial. However, the critical point is that TARP participants were required to appear at the state unemployment office to certify their eligibility, and it is probably reasonable to assume that they believed that payments would not be made to incarcerated individuals. At the very least, the program was introduced to participants in such a manner that this contingency was highlighted.

---

disorderly conduct. Most of the charges included under this rubric consist of quite trivial charges.

[7] It should already be apparent that some important substantive and statistical decisions have been made. In particular, despite the fact that data were available at least by quarter (that is, three-month intervals), we are aggregating up to a year. In fact, we estimated models by quarter for the full year in part to consider lagged effects. However, these efforts were plagued with serious statistical problems, and we will not consider the results here (see Rossi et al., 1980).

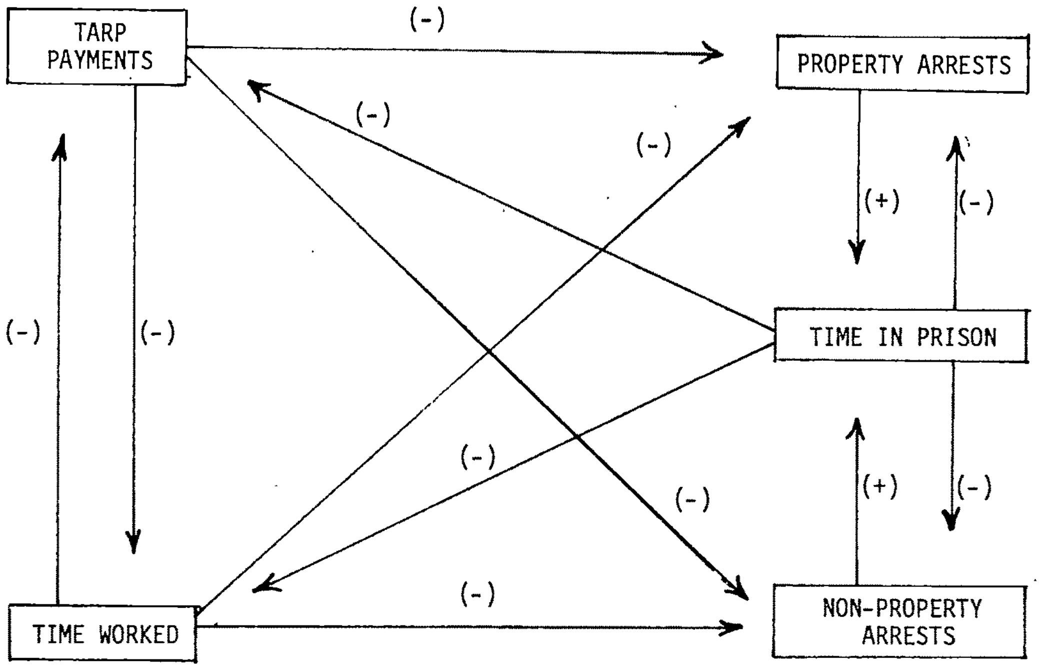

Figure 1. Hypothesized Relationships among Endogenous Variables in TARP Counterbalancing Model.

Third, employment should reduce the number of property and nonproperty arrests because (a) time is withdrawn from illegal activities, (b) the opportunity costs of arrest are increased as a job may now be lost, (c) human capital for legitimate pursuits is enhanced, and (d) preferences for legitimate activities are shaped. In addition, employment should reduce the number of property arrests (only) by providing another source of income (thereby reducing the marginal value of earnings from illegal activities).

The causal relationships just described can be elaborated in a number of interesting ways. For example, it was intended that TARP payments subsidize job search, enabling recipients to obtain positions with better wage rates and/or better working conditions. However, the theoretical background outlined earlier also suggests that TARP payments may subsidize a better search for illegal activities, with TARP recipients engaging in more lucrative and less risky illegal activities. While our data do not allow an analysis of the latter outcome, we can show that ex-felons who received payments did get better jobs (Rossi et al., 1980).

Several important implications follow from the proposed causal relationships among our five endogenous variables. Perhaps most important, TARP payments should have both a positive and a negative impact on property and nonproperty arrests. TARP payments should *directly* reduce the number of property and nonproperty arrests as discussed above. But, in addition, as TARP payments should reduce employment and as reduced employment should lead to a greater number of arrests, TARP payments should *indirectly* increase the number of property and nonproperty arrests. This counterbalancing model implies that a failure to formally consider both the direct and indirect effects may produce misleading results. In particular, the direct positive effects of the TARP payments may be *cancelled out* by the indirect negative effects of the TARP payments.

It should be stressed that many of the arrows drawn in Figure 1 are not speculative in character, but are built into the design of the experiment. Thus, it is the 100% tax on payments that defines the links between employment and TARP payments.[8] Similarly, rules about payment eligibility excluded payments to persons who were in jail or prison or who were too ill to work.

The reader may recall that the earlier Baltimore LIFE experiment operated under different rules and under a different manner of administration. Hence, a modelling of the Baltimore LIFE experiment would remove some of the links shown in Figure 1. In particular, because the experimenters were meticulous in administering a very generous tax rate, the link between employment and payments would have to be modified to indicate the employment did not lead to a loss in payments.

For those who prefer mathematical notation to path diagrams, we now show an abbreviated version of the five-equation nonrecursive model whose parameters we will estimate.

Number Property Arrests = f(TARP payments, employment, incarceration, exogenous variables) (1)
Number Nonproperty Arrests = f(TARP payments, employment, incarceration, exogenous variables) (2)
Number Weeks Employed = f(TARP payments, incarceration, exogenous variables) (3)
Number Weeks Incarcerated = f(property arrests, nonproperty arrests, interaction terms) (4)
TARP Payments = f(interaction terms, exogenous variables) (5)

There remains, of course, the question of what exogenous variables to include. Limited space prevents any extensive discussion of exogenous variables, equation by equation, but there are no surprises. For the first three equations (property arrests, nonproperty arrests, and employment), the exogenous variables fall within four broad groupings: indicators of economic need (for example, gate money and savings), indicators of human capital (for example, education, physical handicaps), indicators of past commitment to the given activity (for example, number of prior convictions), and indicators with unclear theoretical status, but with a history of empirical usefulness (for example, age). It is perhaps worth stressing that the exogenous variables were linked to particular endogenous variables a priori. For example, human capital variables speaking to productivity in legitimate employment were taken to be direct causes of the number of weeks employed. They were *not* taken as direct causes of (reduced) participation in illegitimate activities (that is, the number of property and nonproperty arrests), but could nevertheless affect participation in illegitimate activities indirectly *through* employment. Similarly, measures of past involvement in (and, perhaps, "tastes" for) illegitimate activities were seen as direct causes of arrests for property and nonproperty offenses but were *not* taken to be direct causes of (un)employment. Nevertheless, these measures could affect employment indirectly *through* incarceration resulting from arrests. In any case, specification issues are addressed in somewhat more detail in the next section as findings are considered, and a more thorough discussion can be found in Rossi et al. (1980).

For the last two equations (weeks incarcerated and TARP payments), the exogenous variables reflect either the experimental design (in the case of the last equation) and/or interaction terms. For example, while an ex-prisoner's criminal record may affect the sentence given for a crime, the impact is *conditional* on an arrest. Consequently, the impact of prior record must be represented as a product variable (arrest × prior record). Similarly, the impact of employment on TARP payments is *conditional* on being in one of the experimental groups eligible for support. Again, a product variable is required. We will have more to say about such issues later.

STATISTICAL PROCEDURES

The power of the TARP research design and the richness of the data provide both an unusual analytic opportunity and some difficult analytic problems. Besides the fact that the experimental intervention introduces an important exogenous factor into the system, the other major asset is, perhaps, that the experiment was conducted independently in two states. This means that if one state is taken as the initial site, the other state can be taken as *replication.*

---

[8] There is good evidence that Group 3, which operated under a nominal tax rate of 25%, did not know about the tax rate and, hence, behaved as if they were under the 100% rate.

The replication is critical in part because, even with the aid of theory from economics and sociology, it proved impossible to actually estimate models that were fully consistent with the theory. The major difficulty was that we often had several highly correlated indicators of the same conceptual variable and to have included all of the indicators would have introduced serious multicollinearity. Thus, painful choices had to be made,[9] and these risked capitalizing on type I and type II errors. Consequently, we "fine tuned" the model on the Texas data and then moved it over to the Georgia data virtually intact. With one exception to be discussed later, the only difference between the model specifications in the two states was the availability of comparable variables. For example, IQ scores were readily available for the Texas sample but not for the Georgia sample. The basic point is that if the results in Georgia replicated those in Texas, the impact of the Texas "fine tuning" was probably not serious. (This neglects, of course, the impact of similar specification errors in both states.)

The nonrecursive model required that ordinary least squares be abandoned, and we proceeded with two-stage and three-stage least squares. The former is more robust to specification errors, but is less efficient. The latter is less robust to specification errors, but is more efficient. By and large, the results from the two procedures were much the same, which we take to mean that there are perhaps not serious specification errors. We will, however, report the three-stage least-squares results because its greater efficiency on the average yields (as expected) smaller standard errors.[10]

There remains one problem, however, for which no fully acceptable solution could be devised. All of the endogenous variables are bounded by zero; no negative observations are possible. This implies that the residuals around the regression hyperplane cannot be distributed normally, or even symmetrically. The result is that, in principle, all of the regression coefficients are biased and inconsistent (Tobin, 1958). For single-equation models, relatively simple procedures exist that yield consistent estimates (Amemiya, 1973; Heckman, 1979; Ray et al., 1980). For simultaneous-equation models, however, existing alternatives are only practical for very simple models (e.g., Sickles and Schmidt, 1978). Hence, two fall-back strategies were applied. First, we transformed our most serious truncated endogenous variables into dummy variables (risking heteroskedasticity and, therefore, both inefficiency and biased standard errors) and reestimated the five-equation model. The overall story was much the same, although, as expected, the (biased) standard errors were typically inflated. Second, we undertook a number of transformations of the endogenous variables in an effort to capture the functional form implied by the truncation.[11] Again,

---

[9] The option of confirmatory factor analysis (Jöreskog and Sörbom, 1979) was ruled out as impractical given the large number of equations and variables.

[10] Product variables for which one of the components is an endogenous variable are also vulnerable to simultaneous equation bias. With the aid of reduced form equations with the exogenous component of the product variable removed, instruments for the product variables were constructed and inserted where required. More generally, all of the equations met the order and rank conditions necessary to obtain unique parameter estimates. Finally, it is important to emphasize once again that *any* structural equation model is only as good as its underlying theory and the parameter restrictions implied. In other words, all of our parameter restrictions (that is, to zero) were theoretically based and, should one disagree with our theoretical model, there is no guarantee that our results would hold up under alternative formulations. However, it may be some comfort to know that we did do extensive work testing the sensitivity of our key findings to modest alterations in our specifications (particularly with respect to the exogenous variables) and the major findings were much the same.

[11] Our efforts in dealing with the truncation problems were enormously aided by conversations with Thomas Cooley, Ann Witte, James Heckman, Peter Schmidt and Charles Mallar.

Table 2. Analysis of the TARP Benefits Received (in Dollars)

	Texas		Georgia	
Variable	Coefficient	t-value	Coefficient	t-value
Intercept	0.08	0.66	2.32	0.15
Group 1 (26 weeks/100%)	1,681.12	10.82	1,691.11	7.60
Group 2 (13 weeks/100%)	990.90	4.37	1,021.99	5.27
Group 3 (13 weeks/25%)[a]	738.88	4.67	621.80	3.80
Group 1 × Employment	−17.08	−2.86	−11.59	−1.03
Group 2 × Employment	−7.93	−1.08	−10.65	−1.21
Group 3 × Employment	−0.35	−0.07	3.90	0.58
Group 1 × Jail	−15.23	−1.64	−26.93	−2.02
Group 2 × Jail	−18.29	−1.81	−14.59	−1.07
Group 3 × Jail	−0.00	−0.00	28.21	1.60

[a] Deleted groups are groups 4 and 5.

the story held firm. Thus, we are inclined to believe that the biases created by the truncation are probably not serious although we want to stress that fully appropriate adjustments were *not* undertaken.

FINDINGS AND DISCUSSION

In the interest of space, we have not included tables showing the reduced-form results for Texas and Georgia. With two important exceptions, the substantive findings from the reduced forms are uninteresting, especially in the context of the structural-form results to be reported shortly. The first major finding is that membership in any of the three experimental groups eligible for payments had *no* statistically significant impact on either property arrests or nonproperty arrests. Because in the reduced forms the properties of the randomized design still hold, the null findings cannot be dismissed as a function of specification error or multicollinearity. In short, when the data are analyzed as a randomized experiment with the *orthogonal* treatments defined as membership in one of the experimental groups or the control group (that is, *eligibility* for payments), the number of property and nonproperty arrests is *not* reduced.

Second, the reduced forms reveal a statistically significant (at the .05 level) and nontrivial impact of TARP eligibility on employment. As predicted, there is evidence for a substantial work disincentive—averaging about 5 weeks' less work over the course of 12 months. Had we stopped here, the findings would have been disappointing indeed; the TARP treatment produced no reduction in arrests but did reduce the effort invested in legal employment.

Results from the Payment Equation

Table 2 shows the structural equation results for the equations for Texas and Georgia in which is examined the amount of TARP payments received. It is immediately apparent that in both states the experiments were implemented largely as designed. In both states the intercept is virtually zero with group 1 members receiving about $1,700, group 2 members receiving about $1,000, and group 3 members receiving about $700. With two exceptions, all of the interaction effects (reflecting the TARP design) are in the predicted direction, but only four are statistically significant at the .05 level for a one-tail test. Fortunately, the lack of statistical significance should be no grounds for serious concern because the product variables are, not surprisingly, highly correlated with one another.[12] In summary, the results from our first pair of equations are sensible and consistent with the TARP research design. Were this not the case, it would be almost pointless to proceed.

---

[12] It should also be noted that a fully proper specification would have used interaction terms with *earnings*, not weeks employed. However, the wage data were somewhat suspect and in any case were plagued with large numbers of missing observations.

Table 3. Analysis of the Number of Weeks of Employed

Results for the Number of Weeks Employed

Table 3 shows the two structural equations in which the number of weeks employed is examined. Given the large number of coefficients estimated and the fine tuning applied to the Texas equation, we will proceed conservatively. We will focus on variables that attain statistical significance at the .05 level for one-tail tests (as the hypotheses were one-tailed) in *both* equations. While the probability of observing two coefficients at the .05 level is not .0025 (.05 × .05), in part because of the many tests applied, the chances of type I errors are, nevertheless, dramatically reduced.

To begin with, for each week in jail or prison, the number of weeks worked decreases by about 1.5 weeks. While this is not surprising, the fact that the absolute values of the regression coefficients are greater than 1.0 implies that, often, loss of a job is involved. As suggested earlier, apprehension for illegal activities may well lead to substantial opportunity costs. It is instructive to compare the impact of incarceration with that of the number of weeks sick or in the hospital. Each week of illness and/or hospitalization reduces the number of weeks worked by about three-quarters of a week; the absolute values of the regression coefficients are less than 1.0. Perhaps illness is less likely to mean loss of a job or perhaps ex-prisoners are able to work some of the time when they are "under the weather."[13]

There seems to be little doubt that TARP participants respond to work disincentives. Every $100 of TARP payments reduces the number of weeks worked by about two-thirds of a week. This implies that TARP participants who received maximum benefits of over $1,500 worked an average of 10 less weeks over the 12-

---

[13] It is important to keep in mind that such point estimates have confidence intervals. Thus, the fact that the coefficient is not exactly 1.0 should be no cause for concern.

month interval. In addition, for each $100 dollars that ex-prisoners had on hand at release (for example, gate money, prison earnings, etc.), work effort was reduced by about one-quarter of a week. However, TARP participants rarely had more than a few hundred dollars at the time of release so that the overall impact was typically quite small. Finally, neither the size of savings accounts nor the amount of debt seemed to make any difference in work effort.[14] In summary, at least in the context of employment, there is some support for the assumption of a diminishing marginal utility from income and, as predicted, a nontrivial work disincentive produced by TARP payments.[15]

Three other variables are statistically significant in both equations. Men work an average of about 10 weeks more over the course of a year, and individuals who are more likely to have a job arranged at time of release work several weeks more. Finally, ex-prisoners released on parole work over 3 weeks more during the 12-month interval. Given current skepticism about the efficacy of parole, even the rather modest impact revealed here should give some critics pause. We reasoned a priori that since parole officers often make a concerted effort to have their parolees actively seeking work, an impact on employment would be found. Moreover, our specifications assume that, if being on parole reduces the number of arrests, the impact is mediated by employment. That is, there is no *direct* relationship between parole status and arrests.[16]

Turning briefly to some null findings, it appears that our human-capital variables have little impact. While this would be stunning for a cross-section of the American work force, ex-prisoners are hardly such a cross-section. There is not a great deal of variance in human capital and, for the kinds of jobs ex-prisoners typically seek, the usual human-capital variables may be of limited relevance.[17] Education, reading ability, and prior experience are probably of little importance to employers screening people to wash cars, pick lettuce, sweep floors, and carry heavy boxes. And, as all have criminal records, the one important variable on which employers *might* screen prospective employees is actually constant.

There is also no evidence that members of minority groups fare any worse in the job market. Again, for a cross-section of the American work force, this would be surprising. But one must keep in mind that the kinds of jobs sought by ex-prisoners are at the very bottom of the status heap where employers are unable to routinely pick and choose. In short, for the least desirable jobs society provides, there is apparently equal opportunity.

In this context, however, the fact that men work more than women requires further consideration. The number of women in the sample (126) is far too small to permit a compelling analysis of male-female differences in employment patterns, but there is some suggestion that while being married increases the labor force participation of men, it decreases the labor force participation of women (Jurik, 1979). In other words, although some form of discrimination may well be involved, one cannot rule out a host of other factors resting on such things as the traditional divisions of household labor (Berk and Berk, 1979).

Perhaps the major disappointment in Table 3 is the failure of the overall unemployment rate for the county to which the TARP participant was released to consistently affect employment. The predicted impact surfaces in Texas but not in Georgia. Of course, the overall unemployment rate is at best a very indirect measure of the demand for the labor of ex-prisoners, but we hoped for better.

---

[14] These variables were drawn from the interviews and besides showing little variance were subject to serious measurement error. While ex-prisoners are apparently able to report pretty accurately the amount of money in their possession as they left the prison, their ability to remember the size of their savings accounts (for the few that had them) or their debts was suspect.

[15] If one focused *only* on the employment equation and conceptualized the TARP payments as a lump-sum transfer (that is, an increase in wealth) the decreased work effort might well reflect an increased demand for leisure. However, this appears to be inconsistent with the results of the estimated equation for nonproperty crimes (presumably a "leisure" activity).

[16] Tests of this assumption proved our a priori conception of parole to be correct.

[17] It is probably worth noting in passing that TARP participants had average IQ's.

Results for the Number of Weeks in Jail or Prison

Building causal models for the number of weeks in jail or prison was fraught with problems. To begin with, once we included the obvious predictors of the number of property and nonproperty arrests, all other regressors had to be added as interaction effects with the initial pair. As mentioned before, such variables as prior record should affect incarceration, conditional upon arrest. However, the requisite product variables were necessarily highly correlated with the number of property and nonproperty arrests which in practice meant that only two interaction terms could be inserted. We settled on interactions between arrests and whether the individual was a first offender, after trying several related possibilities in Texas (we did not experiment with the Georgia equation).[18]

At first blush, this might imply that important causal variables were excluded. However, the reduced forms suggested otherwise. The R^2 for Texas was .12 and the R^2 for Georgia was .07, and the reduced forms contained a number of predictors that on theoretical grounds should have been important: number of prior convictions, being on parole, race, and the like. In short, for both Texas and Georgia, but especially for Georgia, we had very little with which to work.

Table 4 shows the structural form results and not a single causal variable is statistically significant in both equations (at the .05 level for a one-tail test).[19] Nevertheless, there is some evidence that a greater number of property arrests leads to a greater number of weeks behind bars. In Texas, the regression coefficient implies that for every property arrest about 17 weeks of incarceration follow (t = 7.89) and, in Georgia, the regression coefficient implies that for every property arrest about 10 weeks of incarceration follow (t = 1.36). In addition, all of the other regression coefficients—with one exception—have the predicted sign. In short, while the effects are small, there are at least no serious anomalies.[20]

To summarize, our data effectively stacked the deck against finding a large number of statistically significant effects. We suspect that greater success would have been attained if the follow-up had lasted 24 months and, in addition, if we had had access to variables more relevant to preconviction jail terms (for example, whether or not bail was raised).

Results for the Number of Property Arrests

With the first three structural equations discussed, we are now ready to deliver the punch line: what is the relationship between economic need and recidivism? And, in particular, did the TARP payments reduce arrests as predicted?

Table 5 shows the results for the number of property arrests. Five regression coefficients attained statistical significance at the .05 level (one-tail test) in both equations and continuing with our conservative strategy we will focus primarily on these.

---

[18] We also tried some interaction terms with endogenous regressors, but the multicollinearity problems were even worse.

[19] We tried specifying and estimating separate equations for the time in prison versus the time in jail, but that proved impractical for a number of reasons. For example, the R^2 from the reduced-form equation for time in jail was so low that the resulting instrument had virtually no variance.

[20] We are somewhat at a loss to explain the disappointing results in Table 4, although we have several speculations. First, the vast majority of incarcerations were for relatively minor offenses and the time in jail often reflected time awaiting an initial hearing before the magistrate, the time before bail was raised, or the time before trial. That is, the endogenous variables are heavily laden with preconviction and, therefore, presentencing experiences. It is probably fair to say that few of our exogenous variables are likely to be especially relevant to these sorts of jail terms. Second, much of the variance in time behind bars for those individuals who were arrested can be attributed to relatively few individuals who committed more serious crimes and, in addition, who committed them early enough in the 12-month interval to be fully processed by the criminal justice system. In other words, exogenous variables that *may* have had important effects at the sentencing stage were relevant for only a rather small number of offenders.

Table 4. Analysis for Number of Weeks in Jail or Prison

	Texas		Georgia	
Variable	Coefficient	t-value	Coefficient	t-value
Intercept	0.67	0.92	0.24	0.32
Number of property arrests	17.09	7.89	10.30	1.36
Number of nonproperty arrests	0.91	0.53	0.48	0.09
First offender × property arrests	−5.63	−1.64	7.04	0.69
First offender × nonproperty arrests	−2.05	−0.49	−3.04	−0.44

To begin, it seems apparent that, within the structural equation framework we have proposed, TARP payments *do* reduce the number of arrests. For Texas, each $100 reduces the number of property arrests by .02 (t = 3.19). This implies that for TARP participants receiving payments near the upper bound permitted by the program, the number of arrests was decreased by .30. For Georgia, every $100 reduces the number of property arrests by .01 (t = 2.21). Again, near the upper program bound of $1,500, the reduction in the number of arrests is about .15. In short, whatever the causal mechanisms (for example, increased opportunity costs, the diminishing marginal utility of income), TARP payments appear to work as predicted.

The number of weeks employed also has the predicted effects. In Texas, each week of employment reduces the number of arrests by .03 (t = 5.15). Thus, individuals who are employed over most of the 12-month interval can be expected to show about 1.5 fewer arrests for property crimes. In Georgia, each week of employment apparently reduces the number of property arrests by about .02 (t = 6.17). Over the course of a 12-month interval, individuals who are employed virtually full time can be expected to experience about 1 less arrest for property crime. Thus, once again, our predictions are supported, although—at this point—almost any set of several competing causal explanations may be involved: increased opportunity costs, diminishing marginal utility of income, increased human capital from legitimate activities, alteration in preferences, and the like. We will have more to say about these issues shortly when nonproperty crimes are considered.

The remaining three findings are at least superficially straightforward and need little elaboration. Men experience on the average about .30 more arrests for property crimes. This mirrors much of the criminology literature although the causal mechanisms are far from clear. The same point holds for the effect of age. Here, each year decreases the number of prop-

a: Dropped because of multicollinearity.

erty arrests by about .01; for many, crime is a bit like a bad case of acne. Finally, each week of illness or time in the hospital decreases the number of property arrests by .03 in Texas and .02 in Georgia.

It may also be worth noting that two other variables perhaps have "real" effect but, nevertheless, fail to meet our conservative criterion for interpretation. There is a hint that a greater number of previous convictions for property crimes increases the number of property arrests and that those TARP participants with a greater number of dependents experience fewer property arrests.

Finally, a brief word about the exclusion of weeks incarcerated from the Georgia equation. As a consequence of the very low R^2 in its reduced-form equation—and the fact that the very few variables that had any predictive value were also strong predictors in the reduced forms for the other endogenous regressors in the equation (payments and employment)—the instrument for weeks in jail or prison produced multicollinearity problems in the property-arrest equation. When included, time in jail or prison yielded a statistically significant, *positive* regression coefficient of nearly .06. This implied that every week in jail or prison *increased* substantially the number of arrests and individuals who were arrested early enough in the 12-month follow-up to spend 40 weeks in jail, for example, experienced 2.5 *more* arrests. Moreover, the cross-equation correlations between the residuals increased enormously, another indicator of implausible and unstable results.[21]

To summarize, two important indicators of financial need appear to reduce the number of property arrests experienced by TARP participants: TARP payments and employment. This pair of results has implications for our proposed counterbalancing model to which we will soon return.[22]

Results for the Number of Nonproperty Arrests

Table 6 shows the findings for the number of nonproperty arrests, and perhaps a few words are needed about specification issues. First, we have approached nonproperty arrests as crimes for which there are very unlikely to be any monetary returns. Consequently, measures of financial need are not included.

Second, given the average nonseriousness of nonproperty arrests, we have assumed that they are more likely to reflect the discretionary practice of local law enforcement agencies. We had no direct measures of these practices but have included dummy variables for major jurisdictions in an effort to capture these effects.[23]

Third, consistent with the view that nonproperty arrests may have little to do with the severity of offenses actually

---

[21] Had we continued to include weeks in jail or prison in the equation, the impact of weeks employed would still have been statistically significant but the effects of TARP payments would *not* have been (in both the two-stage and three-stage least-squares results).

We also experimented with an entirely different specification to take the impact of incarceration into account. In brief, we divided all of the time-dependent variables (for example, weeks employed, property arrests) by the number of weeks "at large" (that is, 52 minus the number of weeks in prison or jail). Hence, all time-dependent variables were standardized for incarceration, and there then was no need for a separate equation predicting weeks in jail or prison. The results for the number of property arrests in Texas were virtually the same as for the five-question model we have been considering. However, the standardization process created some of the same problems for the Georgia property equation that we had been trying to circumvent. The correlation between the residuals for the Georgia property and nonproperty equations soared to .85, making the three-stage results especially suspect. Nevertheless, while t-value for the impact of TARP payments dropped to −.41, the negative impact of employment remained (for both two-stage and three-stage results). Note also that the standardization through the use of ratio variables by itself creates no artifacts, although the impact of measurement error is apparently exacerbated (Long, 1980).

[22] Late in the analysis we tried various kinds of interaction effects. We explored the possibility that the payments, for example, worked "better" for "good risks" (for example, older ex-felons, ex-felons with better work histories, etc.). However, nothing of interest surfaced and very high multicollinearity often resulted. Recall that instruments must be constructed for product variables in which one (or both) of the components is endogenous.

[23] The excluded dummy variable in both states is all rural counties.

b: Not available or does not apply.

committed, we have included several variables tapping characteristics of perpetrators that might predict either a "taste" for nonproperty offenses and/or attributes that might affect police practices: race, prior record, unstable living arrangements, and the like. Finally, we again had to drop weeks in jail or prison from the Georgia equation because of instabilities produced by multicollinearity.[24]

Table 6 indicates that, by and large, the findings for nonproperty arrests are much like those for property arrests. Again employing our conservative strategy of interpreting only regression coefficients that are statistically significant in both states, it seems that each $100 of TARP payments reduces the number of nonproperty arrests in Texas by .02 and in Georgia by .01. While the effects are a bit smaller than for property arrests, the overall impact is nontrivial. For example, $1,500 worth of payments in Texas should reduce the number of nonproperty arrests by .30.

The effects of employment also surface once again. In Texas, each week of employment reduces the number of nonproperty arrests by .03 and in Georgia each week of employment reduces the number of nonproperty arrests by .03. Thus, an individual who found a job shortly after release and worked steadily during the year of follow-up can be expected to experience about 1.5 fewer nonproperty arrests.

Of the remaining variables, men experience about .30 more nonproperty arrests while each week of illness or in the hospital reduces the number of nonproperty arrests by about .02. There is also some evidence that where an ex-prisoner lives makes a difference. Residents of Bexar County experience .39 more nonproperty arrests while residents of Harris County, Tarrant County and Savannah experience about .15 fewer nonproperty arrests. On the other hand, there is no indication that minorities are more subject to arrest, other things being equal.

In short, while there are some interesting differences found for the two kinds of arrests, the TARP payments and employment have almost identical effects for both. However, since nonproperty arrests are very unlikely to involve crimes for which monetary returns are involved, the impact of having more disposable income, per se, is probably not relevant. Rather, the TARP payments may operate through the greater opportunity costs of apprehension. The employment effects may operate by (a) withdrawing time from competing activities, (b) raising the opportunity cost of apprehension, and (c) shaping the preferences of TARP participants toward more law-abiding behavior.

---

[24] As in the case of property arrests, we tried to reduce the problems caused by our incarceration variable through standardization; we standardized each time-dependent variable for the number of weeks "at large." And, again, there was evidence of serious statistical problems. Nevertheless, employment continued to have its effect, and, while TARP payments were no longer statistically significant, t-values hovered around −1.50.

CONCLUSIONS

The analysis of the TARP experiment suggests both methodological and substantive conclusions. From the methodological perspective, the importance of *creating* variance in critical exogenous variables is highlighted. A host of technical difficulties inherent in data resting on naturally occurring variation may be surmounted. In addition, the potential merits of structural equation modeling to supplement the usual analyses of randomized experiments (that is, analysis of variance) is apparent. Had we not attempted to model the system of relationships affected by the TARP payments, a very different and incomplete story would have emerged. Finally, given all of the complexities and uncertainties of structural equation modeling, replications are clearly desirable. Without the Georgia replication, many of our most important findings could be rather easily dismissed.

From a substantive perspective, our counterbalancing model has several important implications for the relationship between poverty and crime among ex-offenders. First, it appears that experimentally induced unemployment does increase arrests for both property and nonproperty crimes. Moreover, the effect is direct and nontrivial; ex-prisoners who are unemployed have more difficulties with the criminal justice system. Second, modest transfer payments appear to reduce arrests for property and nonproperty crimes. Poverty is apparently causally related to crime at the individual level. Third, modest income transfer payments, especially when made conditional upon unemployment, produce substantial work disincentives.[25] In this context, it is important to bear in mind that the rules of the experiment as administered meant that often a 100% tax was placed on earnings (that is, TARP payments were reduced, dollar-for-dollar, for earnings received). Furthermore, work disincentive effects could have been expected to be large because the employment opportunities available to TARP participants were poor competition for the payments. Wages of between $100 and $150 per week before taxes earned at hard and/or unpleasant tasks can hardly appear to be extraordinarily appealing, compared to $60 or $73 per week obtained without working.

More broadly viewed, perhaps the most important substantive conclusion from the TARP experiment concerns the ability of a blend of theory from economics and sociology to explain at least some of the sources of variation in criminal behavior. For ex-offenders at least, unemployment and poverty do cause crime on the microlevel. Modest amounts of financial aid can reduce recidivism among ex-felons. Experimentally induced unemployment can increase recidivism. The mechanisms producing these two effects can be anticipated on the basis of a priori theoretical ideas from microeconomics and sociology.

Finally, there are also policy implications that can be drawn from the findings. A policy that would extend unemployment insurance benefits to released prisoners on a modest level will not increase recidivism overall. Hence, on purely humanitarian grounds, it is possible to argue for such a policy. When we also consider that the burdens of postprison support fall largely on families subsisting at very marginal levels, a good case can be made for implementing the policy as tested in Georgia and Texas. Modest extensions of the unemployment benefit system to released prisoners would transfer some portion of those burdens to the public sector.

---

[25] While it is difficult—and perhaps hazardous—to compare the work-disincentive effects of the negative income tax payments offered in the income maintenance experiments with those experienced in the TARP experiments, it does appear that the TARP payment disincentive effects were several magnitudes larger. Of course, tax rates were different (and more generous in the income maintenance experiments), the populations were markedly different (intact families as opposed, mainly, to single males in the TARP experiments), etc.

Although it may appear difficult to devise a payment plan that would be stripped of work disincentive effects, the experiences of the earlier LIFE experiment at least suggest that it may be possible to do so. A generous tax rate that is faithfully administered may provide positive incentives for working, as the LIFE experience seems to indicate. It is also possible to build into payments stronger incentives than a generous tax rate, for example, actually increasing payments for a time if the ex-felon becomes employed.[26] Indeed, this direction appears so promising that an additional program of experimental research appears indicated. Such a program would investigate alternative ways of reducing work disincentives of payments through testing of generous tax rates and positive incentives for employment.

[26] Richard A. Berk and David Rauma are currently evaluating a program in California providing unemployment benefits to ex-offenders based on eligibility earned from *prison* jobs. While the analysis is still in very preliminary stages, there is evidence that some kinds of transfer payments do not induce unemployment. In particular, parole officers often give grants and loans to parolees (often involving several hundred dollars) *conditional* upon the parolee making a serious effort to obtain work. For example, parole officers will often provide money to have a parolee's car repaired if the parole officer is convinced that the parolee needs a car to get to work and that a serious job search is underway. These transfer payments do not appear to induce unemployment.

SOCIAL NETWORKS AND SOCIAL MOVEMENTS: A MICROSTRUCTURAL APPROACH TO DIFFERENTIAL RECRUITMENT*

DAVID A. SNOW

American Sociological Review 1980, Vol. 45 (October):787–801

Past examinations of differential recruitment to and the differential growth of social movements have typically sought explanation at a social psychological/motivational level of analysis. That focus has recently been called into question by scholars concerned with the process through which movement organizations expand their ranks and mobilize support for their causes. Yet, as Useem (1975) and Zald and McCarthy (1979) have noted, there has been little systematic research conducted on the details of the influence process. Drawing on data derived from a synthesis of existing research and two primary sources, this paper attempts to shed greater empirical and theoretical light on the movement recruitment process. The findings indicate that differential recruitment is not merely a function of dispositional susceptibility, but is strongly influenced by structural proximity, availability, and affective interaction with movement members. The findings also indicate that a movement organization's network attributes function as an important determinant of its recruitment strategies and growth.

Among the various issues and questions relating to the study of social movements, few have generated as much discussion and research as those pertaining to differential recruitment. Why are some people rather than others recruited into a particular social movement organization?[1] Given the number of competing and functionally equivalent movement organizations frequently on the market at the same time, how is it that people come to participate in one rather than another? Why do some movement organizations attract a larger following and grow at a more rapid rate than others? Whether one scans the literature on religious cults and movements, political protest, the ghetto revolts of the 1960s, or student activism, the problem of differential recruitment surfaces as a dominant focal concern, both theoretically and empirically. Indeed, the study of movement recruitment has been "one of the most prominent characteristics of collective behavior research in recent years" (Marx and Wood, 1975:388).

Nonetheless, understanding of the process of differential recruitment, its underlying determinants, and implications for the spread and growth of social movements is still quite limited (Marx and Wood, 1975:393). As Zald and McCarthy (1979:240) concluded in their recent review of the resource mobilization approach, very little is known about the movement recruitment process and the conditions under which various recruitment techniques are more or less successful.

The purpose of this article is to advance understanding of the movement recruit-

We wish to thank the anonymous reviewers and the editors of *ASR* for their insightful and instructive suggestions. Preparation of the article was partially funded by a grant from the University Research Institute, University of Texas.

[1] Here we are following McCarthy and Zald's (1977:1217–9) distinction between a social movement and a movement organization. They define a social movement as "a set of opinions and beliefs in a population which represents preferences" in support of or opposition to social change. A social movement organization is defined as "a complex, or formal, organization which identifies its goals with the preferences of a social movement or a countermovement and attempts to implement those goals." We think this is a conceptually useful distinction since individuals are recruited into and devote time and energy to movement organizations.

ment process by assembling quantitative and qualitative data which bear on the relationship between movement recruitment and such microstructural factors as social networks, and by developing a set of corresponding propositions. Four focal questions structure the inquiry: (1) What are the microstructural avenues of movement recruitment? (2) What accounts for the differential availability of people for movement participation? (3) What are the structural characteristics of social movements which predict different recruitment strategies and patterns? (4) What implications do different recruitment strategies and patterns have for the spread and growth of a movement?

DATA AND PROCEDURES

The article draws on three sets of data. The first is derived from an examination of social movement case studies through which we synthesize quantitative data pertaining to the recruitment process. References to the salience of such microstructural factors as social networks are not uncommon, but our review of the literature revealed that most of the references tend to be impressionistic. There is a dearth of hard data specifying the function of social networks in relation to differential recruitment to and the differential spread and growth of movements. However, we did find ten studies with quantitative data bearing directly on the recruitment process. The sample size of the ten studies varies from 31 to 310 participants, with the combined N totalling more than 1,200.

The second data set comes from an examination of recruitment to the Nichiren Shoshu Buddhist movement in America.[2] These data were derived from the senior author's observations and experiences as a participant-observer for a year and a half, his informal interviews with recruits and members, and his examination of a random sample of members' testimonies appearing in the movement's newspaper, *The World Tribune.*[3] Since most editions of the newspaper contain several members' testimonies, 504 were randomly selected from 1966 to 1974 (six per month), excluding a two-year period in which the newspaper was not readily available. Three hundred and thirty of the 504 testimonies provided information specifying mode of recruitment into the movement. These 330 cases, coupled with 15 other members from whom recruitment information was informally elicited, yielded a sample of 345. Informal interviews with 25 Hare Krishna devotees supplement the data pertaining to Nichiren Shoshu. Twenty of the interviews were with members of the Krishna commune in Los Angeles, and five were with members of the Dallas commune. The interviews were conducted during the course of six visits to the Los Angeles commune and two visits to the Dallas commune.[4]

The third data set is derived from a nonrandom sample of University of Texas students. A questionnaire designed to gather information pertaining to movement recruitment and participation was administered to 550 students enrolled in ten different university courses in the Spring semester of 1979. The first part of the questionnaire contained a list of twenty-five social movement organizations within the Austin, Texas, area. The respondents were initially asked to indicate for each movement whether they were (a) unfamiliar with it; (b) familiar but not sympathetic or supportive; (c) sympathetic but not a participant; or (d) associated with it as a participant at one time or another. Three hundred of the 550 respondents indicated that they either were movement participants or were sympathetic with the objectives of one or more of the movements.[5] Since we are concerned with differential recruitment, only the responses of the 135 participants and the 165 sympathizers are considered. The sympathetic nonparticipants constitute a kind of control group in that their responses shed light on the question of why it is that people who are in sympathy with and supportive of a movement's value orientation do not always participate in movement activities. A consideration of the responses of both participants and sympathizers should yield a better understanding of differential recruitment.

---

[2] Nichiren Shoshu of America (NSA) is a Japanese-based, culturally transplanted, proselytizing Buddhist movement that seeks to change the world by changing individuals. It was formally introduced into America in 1960 and claims to have since attracted more than 200,000 members, the vast majority of whom are Occidental. For a detailed examination of the movement's ideology, goals, and operation in America, see Snow (1976; 1979).

[3] *The World Tribune* is published five times weekly in Santa Monica, California. It was first issued in August 1964 and now has over 55,000 monthly subscriptions. It constitutes a useful record of the growth and history of the Nichiren Shoshu movement in America.

[4] For a discussion of the origins, goals and ideology, and operation of Hare Krishna, see Daner (1976) and Judah (1974).

FINDINGS AND DISCUSSION

The Microstructural Avenues of Recruitment

Movement recruitment has generally been approached from a social-psychological/motivational level of analysis, with various states-of-mind or psychological attributes posited as the major causal variables (see Cantril, 1941; Feuer, 1969; Glock, 1964; Hoffer, 1951; Klapp, 1969; Toch, 1965). However reasonable the underlying assumption that some people are more susceptible than others to movement participation, that view deflects attention from the fact that recruitment cannot occur without prior contact with a recruitment agent. The potential participant has to be informed about and introduced into a particular movement. Thus, even if one accepts the popular contention that some individuals are predisposed social-psychologically to movement participation, the following question still remains: What determines which potential participants are most likely to come into contact with and be recruited into one movement rather than another, if into any movement at all?

It is a basic sociological tenet that social phenomena are not distributed randomly, but are structured according to aggregate or group membership, role incumbency, and the like. It thus seems reasonable to assume that movement recruitment, rather than being random or merely the function of social-psychological predispositions, will also be structured by certain sociospatial factors. Accordingly, we can begin to answer the above question by considering, first, the various sociospatial settings in which movements and potential participants can come into contact, and, second, the variety of generally available modes of communication through which information can be imparted.

Regarding the first concern, most spatial settings or domains of social life can be conceptualized in terms of a continuum ranging from public to private places.[6] Examples of the former include shopping malls, community sidewalks, airports, bus stations, and city parks. Country clubs, an office, a sorority or fraternity house, and an apartment or home are illustrative of the latter.

The means of information dissemination

[5] Classification of Respondents by Relationship to and Type of Movement

Movement Type	Participants[a]	Sympathizers[b]	Totals
Religious or Psychiatric[c]	54	50	104
Political[d]	81	115	196
Totals	135	165	300

[a] "Participants" refers to those individuals who devote time, energy, and other resources to the movement organization with which they are affiliated. They are what McCarthy and Zald (1977:1221) refer to as the "constituents" of a social movement organization.

[b] "Synpathizers" refers to those individuals who believe in or agree with the goals of a movement or movement organization, but do not devote any personal resources to it. They are what McCarthy and Zald (1977:1221) refer to as "adherents."

[c] Movements classified as "Religious or Psychiatric" include Transcendental Meditation, Church of Scientology, Baha'i, Jehovah's Witnesses, Campus Crusade for Christ, etc.

[d] Movements classified as "Political" include: National Organization for Reform of Marijuana Laws, NOW, Right to Life, Young Socialist Alliance, Lesbian-Gay Alliance, John Birch Society, Common Cause, University Mobilization for Survival (Anti-Nuke), etc.

[6] Following Goffman (1963) and Lyman and Scott (1967), "public places" refer to those regions or areas in a community or society that are freely and officially accessible to most members of that community or society. "Private places," on the other hand, refer to those spatial domains that are off-limits to all but acknowledged members and guests, and in which outsiders are considered as actual or potential intruders.

	PUBLIC CHANNELS	PRIVATE CHANNELS
FACE-TO-FACE	Face-to-face leafleting, petitioning, and proselytizing on sidewalks; participation in public events, such as parades; staging events for public consumption, such as sit-ins, protests, movement-sponsored conventions and festivals.	Door-to-door leafleting, petitioning, and proselytizing; information dissemination and recruitment among familiar others along the lines of promoter's extra-movement interpersonal networks.
MEDIATED	Promotion and recruitment via radio, television, and newspapers.	Promotion and recruitment via mail and telephone.

Figure 1. Classification of General Outreach and Engagement Possibilities for Movement Information Dissemination, Promotion, and Recruitment

can be conceptualized generally in terms of whether they are face-to-face or mediated. By face-to-face communication, we refer to all information, whether it be verbal or nonverbal, that is imparted when two or more individuals or groups are physically present. In contrast, mediated communication refers to information dissemination through institutionalized mass communication mechanisms, such as radio and television, or through institutionalized, but individualized and privatized, communication mechanisms such as the mail and telephone.

The cross-classification of these two dimensions suggests four general and fairly distinct microstructural avenues for movement information dissemination and recruitment. Figure 1 schematically summarizes these alternative avenues, each of which is distinguished by the spatial domain of social life in which contact can be established and the means through which information can be imparted.

Given the alternative microstructural avenues, the question arises as to the relative yield of each in terms of actual recruits. In other words, is recruitment among strangers in public places more productive than recruitment along the other avenues, or are movement recruits typically drawn from existing members' extramovement friends, acquaintances, and kin?

Examination of the movement literature strongly suggests that the network channel is the richest source of movement recruits. Numerous studies allude to the importance of social networks as a conduit for the spread of social movements. While some of these works are theoretical or critical in orientation (Oberschall, 1973; Tilly, 1978; Useem, 1975; Wilson, 1973; Wilson and Orum, 1976), most are empirical studies of religious movements (Bibby and Brinkerhoff, 1974; Dator, 1969; Gerlach and Hine, 1970; Harrison, 1974; Heirich, 1977; Judah, 1974; Lee, 1967; Lofland, 1966; Murata, 1969; White, 1970) or political protest or reform-oriented movements (Freeman, 1973; Jackson et al., 1960; Leahy, 1975; Marx, 1969; Orum, 1972; Petras and Zeitlin, 1967; Pinard, 1971; Tygart and Holt, 1972; Von Eschen et al., 1971; Woelfel et al., 1974; Zurcher and Kirkpatrick, 1976). Although suggestive, few of the investigations provide hard data specifying the relation between social networks and differential recruitment. However, ten studies were found with quantitative data bearing on the recruitment process. Table 1 summarizes the findings of all but one of the studies,[7]

---

[7] Heirich's (1977) findings regarding conversion to Catholic Pentecostalism do not neatly fit into Table 1. However, the findings are consistent with those reported in Table 1. Among the 118 respondents "introduced to the movement by trusted associates," 75% were converts. In contrast, among the 187 respondents who were not introduced to the movement by trusted associates, only 31% were converts. Based on similar findings for other social influence variables, Heirich (1977:667) concluded that "it is clear that members of the movement, when recruiting, turn to previous friends and to persons they meet daily."

Table 1. Studies with Data Specifying Mode of Recruitment to Various Movements (Percentage)

			Mode of Recruitment			
			Recruited through Social Networks			% Recruited Outside Networks[b]
Investigator	Movement	N	% By Relatives	% By Friends, Acquaintances[a]	Tot. % Rec. thr. Ntwks.	
Sills (1957)	March of Dimes	234	[c]	90	90	10
Murata (1969)	Sokagakkai	100	16	76	92	9
Dator (1969)	Sokagakkai	120	65	35	100	[d]
White (1970)	Sokagakkai	[e]	24	86	96	4

Bibby & Brinkerhoff (1974)	Evangelistic Protestantism	132	45	29	74	26
Leahy (1975)	Anti-Abortion	31	26	65	91	9
Judah (1974)	Hare Krishna	63	0	3	3	97

[a] Includes all individuals recruited through networks other than familial or kinship (e.g., occupational, neighborhood).

[b] Includes all individuals recruited by strangers in the street or at mass meetings, or who sought out the movement after learning about it through the public media, or who joined on their own initiative.

[c] Percent recruited by relatives, if any, not reported. Of the 90% recruited through networks, 52% were recruited by friends, 20% through community network, and 18% through organizational and occupational networks.

[d] Data derived from 200 testimonials of American members in a Sokagakkai newspaper. Of the 60% (120) indicating mode of recruitment, none was recruited by strangers or through the media. The reason for the large percentage recruited by relatives is that the majority of the individuals in the sample were American GI's stationed in Japan who were married to Japanese members.

[e] Sample size not given. Percent figures based on the average of three to five different surveys. Percent figure for friends and acquaintances based on the average of three surveys; percent figure for relatives and the last two columns based on the average of five surveys.

[f] Figures based on the compilation of Gerlach and Hine's (1970:79–80) reported findings regarding two separate Pentecostal churches.

[g] Percent recruited by relatives or strangers, if any, not reported. Therefore the actual percentage recruited through networks may have been greater than the 59% reported.

clearly demonstrating the salience of social networks as a recruitment avenue. For each of the movements studied, with the exception of Hare Krishna, extramovement social networks constitute the primary source of recruits.

Our findings regarding recruitment to Nichiren Shoshu are consistent with those just presented. As indicated in Table 2, Nichiren Shoshu members are typically recruited into the movement by one or more members with whom they have a preexisting, extramovement, interpersonal tie. Although Nichiren Shoshu members devote a considerable amount of time and energy to proselytizing in public places, these information dissemination and recruiting forays are not very productive. The senior author accompanied members on over forty such expeditions, and only twice were recruits attracted. In contrast, all but one of the twenty-five Krishna devotees we interviewed were recruited "off the street" by other members who were strangers at the time of contact. (Factors which account for the different recruitment patterns of Hare Krishna and the other movements will be discussed later.)

Table 2. Recruitment Patterns for Nichiren Shoshu and Hare Krishna (Percentage)

Recruitment Avenues	Nichiren Shoshu (N:345) Percent	Hare Krishna (N:25) Percent
Public Places	17	96
Social Networks	82	4
Mass Media	1	0
Mail/Telephone	0	0

The important bridging function of social networks in relation to movement recruitment is further demonstrated by our findings regarding the sample of university students participating in various social movements. Additionally, these findings suggest that network linkages are not only important in accounting for differential recruitment into religious movements, but also for political movements. As indicated in Table 3, 63% of the students participating in political movements were drawn into their respective movement's orbit of influence by being linked to one or more members through a preexisting, extramovement interpersonal tie.

The findings associated with the three data sets not only corroborate each other, but they also clearly demonstrate the importance of preexisting social networks in structuring movement recruitment. It is thus reasonable to suggest the following summary proposition:

> *Proposition 1:* Those outsiders who are linked to one or more movement members through preexisting extramovement networks will have a greater probability of being contacted and recruited into that particular movement than will those individuals who are outside of members' extramovement networks.

The Importance of Social Networks in Accounting for Differential Availability

Proposition 1 and the data in which it is grounded suggest that recruitment among social networks is likely to be more productive than recruitment via the other microstructural avenues. However, the fact remains that not all relatives, friends or acquaintances of movement members participate in movement activities when invited. The findings reported in the preceding section indicate that, for all the movements studied, at least some members were recruited "off the street" or through the public media. The findings pertaining to Hare Krishna in particular suggest that some movements recruit most of their members through channels other than social networks. The question thus arises as to who out of the pool of individuals contacted either through existing ties or through other recruitment avenues is most likely to become a movement participant?

Table 3. Recruitment Avenues of a Sample of University Students Participating in Various Movements (Percentage)

Recruitment Avenues	Movements: Political (N:81) Percent	Movements: Religious (N:54) Percent	Totals (N:135) Percent
Public Places	7	0	4
Social Networks	63	80	70
Mass Media	30	20	26
Mail/Telephone	0	0	0

One plausible answer is suggested by the many works that posit a psychofunctional linkage between social-psychological attributes (conceptualized as susceptibilities) and the goals and ideologies of movements (construed as appeals). According to this view, participation in movement activities is largely a function of certain fertile dispositions, such as alienation (Bolton, 1972; Oppenheimer, 1968; Ransford, 1968), relative deprivation (Aberle, 1966; Dayies, 1971; Glock, 1964; Gurr, 1970); and authoritarianism (Hoffer, 1951; Lipset, 1960; Lipset and Raab, 1973). Although of longstanding popularity, the social-psychological dispositional approach has in recent years been called into question on both theoretical and empirical grounds.[8] Moreover, our research suggests that the reason why some rather than other individuals join a movement once they have been introduced to it can be explained in large part by their structural availability. Specifically, the findings pertaining to Nichiren Shoshu and the sample of movement sympathizers suggest that the reason for participating or not participating in movement activities once invited is largely contingent on the extent to which extramovement networks function as countervailing influences. Since sets of social relationships can be more or less demanding in regard to time, energy, and emotional attachment (Etzioni, 1975; Kanter, 1972), it follows that they can also vary in the extent to which they constitute countervailing influences or extraneous commitments (Becker, 1960) with respect to alternative networks and lines of action. Hence, some individuals will be more available for movement exploration and participation because of the possession of unscheduled or discretionary time and because of minimal countervailing risks or sanctions.

---

[8] Much of the literature touching on the hypothetical association between preexisting social psychological strains and participation in movements suggests a relatively indeterminate relationship (see Aberle, 1965; Bolton, 1972; Marx and Wood, 1975; Petras and Zeitlin, 1967; Portes, 1971; Useem, 1975). Also the magnitude of statistical association between measures of social psychological variables and participation in movements and protest activities has generally been quite small and unconvincing (see Lewis and Kraut, 1972; McPhail, 1971; Moinat et al., 1972; Portes, 1971; Snyder and Tilly, 1972). For varied criticisms of the social psychological-dispositional approach to movement joining, see McCarthy and Zald (1977:1214–5), Snow and Phillips (1980), Turner and Killian (1972:365), Useem (1975:11–18), and Zygmunt (1972).

In the case of Nichiren Shoshu, these observations seem to hold for both those members recruited from the street and those recruited through social networks. Most were under 30, single, in a transitional role (such as that of student), employed in a line rather than in a managerial position, or in a state of occupational marginality. As a consequence, they tended to possess a greater amount of unscheduled time and generally lacked the kinds of extraneous commitments that are likely to inhibit movement participation. Aside from the absence of a social tie to one or more members prior to initial contact, those recruited from the street differed from those recruited through networks only in that they were structurally more available for participation. This observation is illustrated by the following account of how and why one street-recruit, a twenty-five-year-old male, came to join Nichiren Shoshu:

> I found myself here in L.A. with nothing but the clothes I was wearing. I didn't know anybody. I didn't have a lot of money. It was a really strange situation.
>
> I had just flown into L.A. airport, and all my baggage came up missing. This was on a Saturday night. Since I didn't know anybody and didn't have any place to go, I went to the airport police station and was told to go to Travelers' Aid. But I learned that they wouldn't be open until Tuesday, since this was a Labor Day weekend. So I waited around the airport until Tuesday and then went down to Travelers' Aid. They sent me to the Welfare Department. After spending four days waiting and filling out forms, I was told that I couldn't qualify for welfare because I wasn't a California resident.
>
> At this point I didn't know what to do. So I spent a few nights at the Midnight Mission, and then decided to go to the Santa Monica Beach. That evening while I was walking around downtown Santa Monica, this guy came up to me and started talking about Nam-Myoho-Renge-Kyo (the Nichiren Shoshu chant), and asked if I would like to go to a meeting. Since I didn't have anything else to do, I went along.
>
> All of a sudden I find myself at this meeting where everybody was chanting. I didn't have the faintest idea about what was going on. I had never heard of the chant before, and didn't even know there was such a group as NSA. But since everybody was telling me to give chanting a try, I figured why not. I literally didn't have anything to lose. So I joined, and I've been chanting ever since—which is about four months.

Although this account differs somewhat from the stories of other street-recruits in its particulars, it underscores what was common to the life-situation of the 85 street-recruits about whom we were able to gather information.[9] They were either recent arrivals to or passing through the area in which they were recruited, or they were minimally involved in proximal and demanding social relationships.[10] Although one might argue that these street-recruits were "susceptible" to the "appeals" of the movements they joined because they were "social isolates," "loners," or "outcasts," we do not subscribe to such an interpretation. Rather, we think it is sociologically more compelling to argue that individuals who join social movements share the kinds of demographic and social characteristics that allow them to follow their interests and/or engage in exploratory behavior to a greater extent than individuals who are bound to existing lines of action by such extraneous commitments as spouse, children, debts, job, and occupational reputation.[11]

---

[9] The information pertaining to street-recruits is based on the testimonies of 61 Nichiren Shoshu members recruited off the street and on in-depth interviews with two street recruits to NSA and with 24 Hare Krishna devotees.

[10] It thus follows that relatively few people are recruited directly off the streets for two basic reasons: First, most people walking the street are engaged in the business of completing a particular line of action—such as shopping, going to a movie, and the like—and, therefore, have little if any unscheduled or free time when confronted by movement recruiters. Second, most individuals walking the street in most urban areas have a number of fairly strong, proximal social relationships that function as countervailing influences, at least when confronted by a proselytizing stranger.

This microstructural interpretation is also suggested by our findings regarding the movement sympathizers in our sample of university students. By movement sympathizers, we refer to those individuals who indicate verbal support of or agreement with the goals of a movement, but who do not devote any time, energy, or other resources to advancing the movement's objectives. The major reasons given by the sympathizers for remaining on the sidelines and not getting involved are indicated in Table 4. Most relevant to the present discussion is the finding that nearly two-thirds indicated that they did not have enough time to participate. Had their lines of action not been constrained by competing, extra-movement commitments and demands, and had they been asked to participate by a member with whom they were acquainted, then presumably they would have become a participant or "constituent" rather than just a sympathizer or "adherent."

Table 4. Reasons for Not Participating Given by Movement Sympathizers (Percentage)

	Movements		
Reasons	Political (N:115) Percent	Religious (N:50) Percent	Totals (N:165) Percent
1. Didn't know anyone actively involved	73	66	71
2. Not enough time	64	61	63
3. Wasn't asked	57	47	54
4. Just didn't want to get involved	18	16	18
5. Fear of negative reaction by nonmovement significant others	7	12	9
6. Don't know/other	4	4	4

In light of these corroborating findings and observations, it seems reasonable to suggest that, given the existence of a social tie to one or more movement members, differential recruitment is largely a function of differential availability, which is best conceptualized as a microstructural phenomenon. That is, it is a function of how tightly individuals are tied to alternative networks and thus have commitments that hinder the recruitment efforts of social movement organizations. The following propositions summarize the argument. The first pertains to the relation between social networks and availability for movement participation. The second concerns the connection between structural availability and the probability of actual participation.

> *Proposition 2A:* The fewer and the weaker the social ties to alternative networks, the greater the structural availability for movement participation.
>
> *Proposition 2B:* The greater the structural availability for participation, the greater the probability of accepting the recruitment "invitation."

Here it might be argued that even though a social bond with one or more movement members and structural availability increase the probability of movement participation, they are not sufficient conditions. We would agree, especially since social action on behalf of noncoercive organizations is unlikely in the absence of instrumental, affective, or ideological alignment (Etzioni, 1975; Kanter, 1972; Parsons and Shils, 1962). However, it is important to emphasize that people seldom initially join movements per se. Rather they typically are asked to participate in movement activities.[12] Furthermore, it is during the course of initial participation that they are provided with the "reasons" or "justifications" for what they have already done and for continuing participation. As C. Wright Mills emphasized some time ago (1940), vocabularies of motives are frequently supplied "after the act" to explain the "underlying causes of the act," even though they have little to say about how the act came about. We would thus argue that the "motives" for joining or continued participation are generally emergent and interactional rather than prestructured. That is, they arise out of a process of ongoing interaction with a movement organization and its recruitment agents. Although this alignment process has not received much empirical attention, its salience in relation to movement recruitment has been illustrated by Lofland's (1977a; 1977b) reexamination of the process by which one becomes a "Moonie" and by Snow's (1976) description of how Nichiren Shoshu strategically goes about the business of "luring" and "securing" recruits. In both cases the recruitment process is organized so as gradually to "sell" prospects on the "benefits" of participation and to provide them with "reasons" for remaining a member. This is not to suggest that prestructured cognitive states and tensions are irrelevant for understanding movement joining. Rather, it is to emphasize that they must be aligned with the movement's value orientation, given specific forms and means for expression and amelioration, and put into the service of the movement (Zygmunt, 1972).[13] In light of these observations, we argue that initial and sustained participation is largely contingent on the countervailing influence of alternative networks and intensive interaction with movement members. Whereas the first factor determines whether one is structurally available for participation, the second factor gives rise to the rationale for participation.

---

[11] This interpretation is suggested by McCarthy and Zald (1973) in their initial discussion of resource mobilization, and by McPhail and Miller's (1973) treatment of the assembling process. Although one must be cautious about assuming that the dynamics underlying participation in civil disorders and social movements are the same, it is worth noting that this interpretation is consistent with McPhail's (1971) reinterpretation of the riot participation literature, Lachman and Singer's (1968) findings regarding participation in the 1967 Detroit riot, and Snyder and Kelly's (1979) discussion of the development of urban disorders. (Also see National Advisory Commission on Civil Disorders, 1968:123.) Darley and Batson's (1973) work on helping behavior also suggests that unscheduled or discretionary time is perhaps the most important determinant of Good Samaritanism.

Structural Influences on Movement Recruitment Strategies and Patterns

In analyzing the recruitment process from the point of view of the movement itself, the relationship between movement structure (as determined by its network attributes) and recruitment opportunities and patterns requires attention. As indicated earlier, there are four general outreach and engagement channels that movements can exploit for information dissemination and recruitment: (1) They can channel their promotion and recruitment efforts among strangers in public places by face-to-face means; (2) They can promote via the institutionalized, mass communication mechanisms; (3) They can recruit among strangers in private places by such means as door-to-door canvassing; (4) They can promote and recruit through members' extramovement social networks. The question thus arises as to what determines the patterning and channelling of a movement's recruitment efforts.

Depending on their resource base and strategy, all nonsecretive movement organizations interested in expanding their ranks can exploit the first three recruitment possibilities. However, not all such movements are structurally able to use the network channel to the same extent since they do not all constitute open networks. Some movements are more restrictive and exclusive than others in that membership eligibility is contingent on the possession of certain ascribed or achieved attributes. In other movements, such as Hare Krishna, core membership may even be contingent upon the severance of extramovement interpersonal ties. Since movement organizations can vary in the extent to which they are linked to or isolated from other networks of social relations, it follows that their recruitment opportunities can vary considerably. Accordingly, it seems reasonable to suggest the following propositions regarding the relation between a movement's network attributes and the channelling and patterning of its recruitment efforts:

---

[12] This has been amply illustrated by a number of studies. In his examination of recruitment and conversion to the Unification Church, Lofland (1977a:306) found that initial contact "commonly involved an invitation to dinner, a lecture, or both" (see also Bromley and Shupe, 1979:171–4). Snow's (1976) findings regarding the recruitment practices of the Nichiren Shoshu movement reveal similar patterns. When recruiting in public places, Nichiren Shoshu members coaxed prospects to attend discussion meetings, chanting sessions, and other movement activities. Our observations of the recruitment efforts of Krishna devotees also indicate that the first step was to get prospects to the local temple. They were invited to attend a devotional session, to listen to discussion of the philosophy, or to attend a Sunday "love feast" (see also Judah, 1974).

[13] In arguing that the "motives" for movement participation are largely emergent and interactional in character, we are at least implicitly questioning the rational calculus assumptions accepted by resource mobilization theorists. That perspective is most clearly represented in the work of McCarthy and Zald (1973; 1977) and Oberschall (1973). For an extensive critique of this "utilitarian" strand of resource mobilization theory, see Fireman and Gamson (1979) and Zurcher and Snow (forthcoming).

> *Proposition 3A:* Movements requiring exclusive participation by their members in movement activities will attract members primarily from public places rather than from among extramovement interpersonal associations and networks.
>
> *Proposition 3B:* Movements which do not require exclusive participation by their members in movement activities will attract members primarily from among extramovement interpersonal associations and networks, rather than from public places.

These two propositions are suggested when we compare our findings regarding recruitment into Nichiren Shoshu with those pertaining to Hare Krishna. As mentioned earlier, more than three-quarters of our sample of NSA members reported that they were recruited into the movement by relatives, friends, or acquaintances. In contrast, only one of the twenty-five Krishna devotees we interviewed was recruited by a former acquaintance. Judah (1974:162) similarly found that only 3.32% of the Krishna devotees he interviewed "learned about it through a friend who was a devotee." The majority (66%) came into contact with the movement by encountering a public chanting session or a devotee in the street. Judah (1974:162–3) concludes that

> . . . the results seem to indicate rather clearly the importance of the Movement's method of proselytizing. It has attracted the attention of many by its practice of chanting the Hare Krishna mantra in public. During these public ceremonies, other devotees sell the literature and engage the curious in conversation about Krishna.

Anyone with firsthand knowledge of the Krishna movement will find little reason to quibble with Judah's (1974) observations. However, he fails to note that the movement in general and devotees in particular have little choice other than to turn to the streets in search of recruits. Since core membership in Hare Krishna requires an austere communal lifestyle and the severance of extramovement interpersonal ties, the movement is structurally compelled to concentrate its recruitment efforts in public places. Consequently, most of its members are recruited "off the streets."

In contrast, the Nichiren Shoshu movement does not involve communal life or require its members to sever their extramovement interpersonal ties. It is, therefore, structurally able to recruit both in public places and through members' extramovement networks. Consequently, it draws the bulk of its membership from those networks.

Implications of Recruitment Strategies for Movement Spread and Growth

The differential spread and growth of social movements has generally been analyzed in terms of the appeal of movement goals and value orientations to various target populations in the ambient society. That a movement's organizational structure, and particularly its network attributes, might function as an important determinant of its spread and growth has received only brief attention in the literature (Curtis and Zurcher, 1973; 1974; Messinger, 1955; Zald and Ash, 1966; Zurcher and Kirkpatrick, 1976). We now address this issue. Specifically, do differences in network attributes and recruitment opportunities have a significant impact on the success of a movement's recruitment efforts, as measured by the number of outsiders actually recruited? The answer hypothetically depends not only on a movement's value orientation, but also on whether recruitment among social networks typically yields a greater return than does recruitment "off the street" or through the media. If the latter is generally more productive, then a movement's network attributes would be of little relevance to its overall growth. However, if recruitment among strangers is not as effective as recruitment among movement members' acquaintances, friends, and relatives, then a movement's network attributes would constitute a significant and important variable in relation to its growth and spread.

Our findings indicate that for those movements which recruit both in public places and through networks, recruitment among acquaintances, friends, and kin is generally more successful than recruitment among strangers. We thus conclude that a movement's network attributes and corresponding recruitment patterns do indeed make a significant difference in a movement's recruitment efforts and growth. Hence, the following propositions:

> *Proposition 4A:* The success of movement recruitment efforts, measured by the numbers of outsiders actually recruited, will vary with the extent to which movements are linked to other groups and networks via members' extramovement interpersonal ties, such that:
>
> *Proposition 4B:* Movements which are linked to other groups and networks will normally grow at a more rapid rate and normally attain a larger membership than will movements which are structurally more isolated and closed.

Aside from a few exceptions (Craven and Wellman, 1974; Curtis and Zurcher, 1973; Turk, 1970), most social network analyses have focused on the individual and his or her interpersonal ties, with a paucity of social ties taken as evidence of objective or structural social isolation. That focus may be useful for understanding the structural determinants of individual behavioral patterns and propensities. However, it obscures the fact that social isolation can also occur at the group or movement level, as when a movement has few, if any, direct links with other groups and therefore constitutes a closed network or insulated system of social relations. When this occurs, Propositions 4A and 4B suggest that such movements will differ markedly from structurally less isolated movements in recruitment opportunities and patterns, and overall growth.

Empirical support is provided for the propositions by a comparison of the membership claims of the Nichiren Shoshu and Hare Krishna movement organizations in the United States. Since 1970 Nichiren Shoshu's membership claims have consistently hovered between 200,000 and 250,000. In contrast, members of the Los Angeles and Dallas Krishna communes have reported that the number of communal Krishna devotees throughout the country totals no more than 4,000. While efforts to reach an objective estimate of Nichiren Shoshu's membership suggest that it is about half of what the movement claims (see Snow, 1976:137–44), the point still remains that Nichiren Shoshu's membership far exceeds that of Hare Krishna. Given the fact that both are active, proselytizing movements, the question arises as to why the spread and growth of Nichiren Shoshu have far outdistanced those of Hare Krishna. Differences in the value orientation, promises, and membership demands of the two movements certainly constitute important variables in accounting for the difference in their spread and growth.[14] However,

---

[14] Regarding the differences in the value orientations and promises of the two movements, Nichiren Shoshu is more practical and this-worldly in orientation. Rather than calling for a renunciation of worldly attachments and promising a transcendence of the material world, as is the case with Hare Krishna, Nichiren Shoshu promises the realization of personal enlightenment and happiness in the immediate here-and-now. It is thus reasonable to assume that Nichiren Shoshu would appeal to a greater number of people than would Hare Krishna. Relatedly, membership in Nichiren Shoshu is much less demanding. Not only are Krishna devotees required to surrender to the movement their personal possessions and desiderata, but they are also required to sever their preexisting, extramovement interpersonal associations and ties. In contrast, Nichiren Shoshu members are merely required to surrender some time and energy, and perhaps be willing to risk a negative

Propositions 4A and 4B point to a perhaps more significant determinant of the differential spread and growth not only of these two movement organizations, but also of social movement organizations in general: the extent to which a movement organization is linked to or structurally isolated from other groups and networks within its environment of operation.

SUMMARY AND CONCLUSIONS

In recent years the study of differential recruitment to and the differential spread and growth of social movements has been characterized by concern with the process through which movement organizations strategically expand their ranks and mobilize support for their cause. Yet, as both Useem (1975:43) and Zald and McCarthy (1979:240) have noted, there has been relatively little systematic research conducted on the details of the influence process. In order to shed greater empirical and theoretical light on the recruitment process, we have presented data derived from three sources. Our findings indicate that the probability of being recruited into a particular movement is largely a function of two conditions: (1) links to one or more movement members through a preexisting or emergent interpersonal tie; and (2) the absence of countervailing networks. The first condition suggests who is most likely to be brought directly into a movement organization's orbit of influence and thereby subjected to its recruitment and reality-construction efforts. The second indicates who is structurally most available for participation and therefore most likely to accept the recruitment invitation. Our findings also indicate that a movement's recruitment strategies and its resultant growth will vary considerably in the degree to which it constitutes a closed or open network of social relations. Taken together, these findings indicate that both the network attributes of movement organizations and members function as important structural determinants of differential recruitment to and the differential growth of movement organizations.[15]

Several theoretical and empirical implications are suggested by our findings and correspondent propositions. First, in contrast to the traditional assumption that movement recruitment efforts are largely a function of goals and ideology, our findings indicate that the mobilization process in general and the recruitment process in particular are likely to vary significantly with changes in organizational structure. Indeed, our findings indicate that movement goals and organizational structure may occasionally contradict each other. When this occurs, as in the case of Hare Krishna, the organizational structure will function as the more important determinant of recruitment patterns.

Second, since social networks constitute microstructures, the findings suggest that microstructural variables are of equal, and perhaps greater, importance than dispositional susceptibilities in the determination of differential recruitment. We do not urge that dispositions be wholly ignored in attempts to understand the recruitment process. The notion "disposition" perhaps usefully could be integrated with the network perspective by conceptualizing it in terms of the normative, instrumental and affective ties among current and potential participants. People can become encapsulated (Lofland, 1977a; 1977b) by a movement when they are "dispositionally" linked to the proselytizing network, and when that connection becomes expanded by exposure to increasingly broadened socialization messages.

---

reaction by nonmovement significant others. In short, not only is it easier to be a Nichiren Shoshu member than a Krishna devotee, but Nichiren Shoshu adherents also live in and are "into" the here-and-now material world to a much greater extent than are the saffron-robed chanters and promoters of the Krishna mantra.

[15] Our concentration upon microstructural factors in movement recruitment is not intended to detract scholars from equally necessary macrostructural probings of movement emergence, growth and decline. Blumer's (1951) identification of general social movements as seedbeds for specific movements remains heuristically important. The shifts in societal trends, especially in values and their interpretations, can influence the relevance of networks (and rhetoric in networks) for potential movement recruits.

Third, our analysis suggests that the question of "why" people join social movements cannot be adequately understood apart from an examination of the process of "how" individuals come to align themselves with a particular movement. Indeed, it is our contention that the "whys" or "reasons" for joining arise out of the recruitment process itself. We would thus argue that further examination of movement joining and participation should give more attention to how movements solicit, coax, and secure participants, and more attention to the factors that account for variations in recruitment strategies and their efficacy. An examination of such factors should move us beyond our current knowledge about the recruitment process, which has, according to Marx and Wood (1975:393), reached "a point of diminishing returns."

THE DIFFERENTIAL SENTENCING OF WHITE-COLLAR OFFENDERS IN TEN FEDERAL DISTRICT COURTS*

JOHN HAGAN

Indiana University

CELESTA ALBONETTI
Indiana University

American Sociological Review 1980, Vol. 45 (October):802–820

While sociologists have long debated the relationship between the status characteristics of criminal offenders and the sentences they receive, they have done so with data sets drawn from state courts whose prosecutorial resources are focused almost entirely on low status defendants. Qualitative and quantitative data analyzed in this paper are drawn from ten federal district courts whose statutes and resources provide greater potential for the prosecution of the white-collar crimes of higher status offenders. Three questions are addressed: (1) Are there substantial jurisdictional differences in the prosecution of white-collar cases? if so, (2) Are there corresponding jurisdictional differences in the sentencing of white-collar cases? and (3) Within jurisdictions, are there further differences in the factors that influence sentencing decisions in white-collar as compared to other kinds of cases? The data are analyzed from a perspective that emphasizes organizational considerations: we conceptualize the criminal justice process as a loosely coupled system and the use of prosecutorial resources as proactive and reactive. We argue that the expanded prosecution of white-collar persons for their white-collar crimes requires a proactive prosecutorial policy and a tightening of the coupling between plea negotiations and sentencing decisions in the prosecutorial and judicial subsystems. Our quantitative analysis reveals that one district follows a uniquely proactive pattern. As expected, this proactive district also exhibits a unique leniency in the sentencing of college educated white-collar criminals that is related to earlier plea and charging decisions. A rather different and unanticipated pattern of leniency is found in this district for less educated white-collar offenders. A conclusion of this study is that there may be an inverse relationship between the volume of white-collar prosecutions and the severity with which they are sentenced.

The existence of systematic links between the status characteristics of criminal offenders and the sentences they receive has been debated for some time (see Hagan, 1974). This debate is grounded in issues of theory and policy. For example, Chiricos and Waldo (1975) regard a relationship between class position and sentencing as crucial to one prominent version (Chambliss and Seidman, 1971) of a conflict theory of crime, while the absence of such a relationship is usually deemed essential to notions of "equality before the law." It therefore is not surprising that this type of debate has generated a large volume of research (see Nettler, 1979:40–6). What *is* surprising is the inconclusiveness of the findings that flow from this work.

The problem is not simply that these findings are inconsistent, although they are that. For all the studies that find little (e.g., Bernstein et al., 1977) or no (e.g., Chiricos and Waldo, 1975) relationship between status characteristics and sentencing, there are still those that find this relationship to be substantial (e.g., Swigert and Farrell, 1977; Lizotte, 1978). However, the larger issue is that the data sets on which these studies are based are widely thought to be inadequate. Specifically, critics (e.g., Greenberg, 1977; Hopkins, 1977; Reasons, 1977) note that the samples considered in these studies consist almost entirely of low status defendants, making this research mainly a matter of within- rather than between-class comparisons. Thus, while (to date) research of this type has focused on the sentencing of "traditional" or "common"

Research reported in this paper was funded by the Crime and Delinquency section of the National Institute of Mental Health. The authors wish to thank the anonymous reviewers of this manuscript for their helpful comments.

crimes (e.g., murder, robbery, larceny, etc.), Hopkins (1977:177) points out that "The illegal activities of the middle and upper classes are typically such things as income tax evasion and, in the case of businessmen, price fixing, violation of pollution laws and misrepresentation in advertising."

Three problems account for the failure of recent research to consider the latter kinds of crimes, which usually are designated vaguely as "white-collar crimes." First, there is an uncertainty about what, and who, to study. The difficulty is that not all white-collar crimes (e.g., income tax violations) are committed by white-collar persons, and not all white-collar persons commit white-collar crimes (e.g., the crimes of Patty Hearst). We respond to this problem in this paper by cross-classifying indicators of the status of the offender *and* the offense. This allows us to compare the prosecution and sentencing of the white-collar crimes of white-collar persons with the prosecution and sentencing of other offender-offense combinations (see later pages, herein, for further elaboration of this point). Second, the former kinds of white-collar crimes are prosecuted with their greatest frequency in the American federal courts. To date, most sociological research on sentencing has been done in the state courts. Third, much of the white-collar crime of white-collar persons is "beyond incrimination" (Kennedy, 1970). That is, much of this white-collar "indiscretion" is handled in the civil courts, or not dealt with at all. However, this situation shows signs of change.

Some U.S. Attorney offices recently have begun to take increased initiative in the prosecution of white-collar persons and their white-collar crimes. The quantitative data analyzed in this paper consist of cases prosecuted and sentenced over a several-year period in ten federal district courts, including one of the first U.S. Attorney offices in this country reputed to have made the prosecution of white-collar cases a high priority; qualitative data, as well, were gathered through observations and interviews in these courts. The latter data are used first to ground the following discussion of "white-collar justice."

THE SOCIAL ORGANIZATION OF WHITE-COLLAR JUSTICE

To understand the sanctioning of white-collar persons and their white-collar crimes we must consider the system in which this occurs. In this section, we develop a perspective for viewing the operations of this system. The perspective we offer is derived from the work of others and from the interviews and observations gathered in site visits to the ten district courts. The districts and their principal cities are Eastern and Southern New York (Brooklyn and Manhattan), Northern Illinois (Chicago), Eastern Pennsylvania (Philadelphia), Maryland (Baltimore), Northern Texas (Dallas), Western Missouri (Kansas City), Northern Georgia (Atlanta), Central California (Los Angeles), and Eastern Michigan (Detroit). During the site visits we observed approximately 200 hours of court proceedings and conducted approximately 600 hours of interviews with the following court personnel: 9 Chief Judges and 42 Presiding Judges, 8 United States Attorneys and 48 Assistant United States Attorneys, 14 Probation Officers, 15 Administrators of Pre-Trial Services Agencies, 31 Magistrates, and 10 Chiefs of Public Defender Offices.[1]

Reiss (1971; 1974) conceptualizes the criminal justice system as a loosely articulated operating network of input-output relationships among a series of subsystems; a set of relationships that we will refer to as a "loosely coupled system" (Hagan et al., 1979; see also Meyer and Rowan, 1977). Discretion is dispersed throughout this system, and mechanisms for systematizing this discretion appear to be the exception as much as the rule. Thus, Gibbs (1978:105) observes that "... the system actually appears to be an ungoverned mishmash," and Eisenstein and Jacob (1977:37) note that even "the judge does not rule or govern; at most, he manages, and often he is managed by others." Reiss (1971:120) goes on to suggest that "the major means of control among the subsystems is *internal* to each" with the significant consequence that "each subsystem creates its own system of justice." This situation becomes problematic when the attempt is made in such a system to establish or shift policies and priorities. Indeed, one of the fascinating features of loosely coupled systems is their ability to circumvent such changes (see Meyer and Rowan, 1977).

---

[1] These interviews were conducted over a ten-week period, with one week spent in each of the ten districts. The ten jurisdictions comprise a purposive sample selected by the Supreme Court (under provisions of the Speedy Trial Act; see fn. 4) and intended to maximize the representation of major metropolitan and geographic areas across the United States. The first two authors of this paper conducted the interviews together, using a set of structured, open-ended interview schedules that are available on request. Our purpose was to interview a cross-section of court personnel across the ten districts. Unedited excerpts from these interviews are quoted in this article. One Chief Judge refused to be interviewed and two U.S. Attorneys were not available for interviews. However, the First Assistant to each of the latter U.S. Attorneys was interviewed and our coverage otherwise was quite comprehensive. These qualitative data were generated to correspond to the quantitative data discussed later in this paper.

Yet important changes in policies and priorities sometimes do occur, with systemwide repercussions. Within the criminal justice system, such changes are often implemented through the prosecutorial subsystem. Reiss (1974:690) indicates why and how:

> By legal authority and by practice, prosecutors have the greatest discretion in the formally organized criminal justice network. . . . The way that prosecutors exercise discretion over input and output varies considerably among jurisdictions. This variation is due partly to the organized forms of discretion available to a prosecutor in a given jurisdiction and partly to historical practice within that office. The discretionary decisions of prosecutors whether or not to file information can exercise substantial control over input into the system, while the quantity and quality of output are determined mainly by their decisions to nol pros or to plea bargain.

Drawing from Reiss (1971), Black (1973) and our own interviews, we suggest that this prosecutorial power can be exercised in two principal ways.

On the one hand, prosecutors can follow a *reactive* policy of law enforcement. Following this strategy, prosecutors can respond to police initiatives in the same way in which the police do to citizen complaints. That is, prosecutors can simply respond to what the police bring to their attention. Indeed, the influx of cases, the absence of ready avenues of diversion, and the scarcity of resources is such that most *state* courts can do little but react, and slowly at that. These are "courts of last resort." Many federal prosecutors also are reactive. Their assumption is often that court resources are most efficiently organized to satisfy the demands of enforcement agencies. This assumption is reflected in the explanation given us by a U.S. Attorney for his reluctance to pursue one type of white-collar crime.

> It would be nice to investigate, let's say, public corruption. "Okay, FBI, I want you to go out and develop snitches in all the HEW places where they might be taking bribes" . . . but God knows how much time [that would take] and we don't have the resources to do that. If I had some prosecutors or some agents to whom I could say, "Okay, I don't mind you wasting a year investigating this because we want it looked into," then I could see doing that. But if you don't have the resources to do it, I just don't feel you are using your resources right.

This reactive view is summarized in a quote from another U.S. Attorney interview: "In my opinion, any time you deny an agency the right to enforce its federal laws, you are not doing the job you are put here for."

Other federal prosecutors find, in their roles, sources of flexibility that allow the development of *proactive* policies. First, federal prosecutors have jurisdiction over a broad range of white-collar offenses. Second, federal prosecutors can decline cases or defer them to state courts, reserving resources for cases they assign higher priority. Third, the ratio of personnel to cases is usually more favorable in federal than in state courts. Fourth, federal prosecutors often have investigatory resources—particularly, federal agencies like the Federal Bureau of Investigation, the Postal Service and the Internal Revenue Service—that the state courts do not. Consequently, U.S. Attorney offices in several large jurisdictions allocate their resources to proactively initiate and encourage the investigation and prosecution of high priority cases. Thus, one U.S.

Attorney interviewed noted that "In terms of the decision-making process of how and what cases will be handled and what will be done, a lot [of decisions] are being made here and not in the agency." One way this is done is as follows.

> The U.S. Attorney's office can investigate cases in the grand jury, where it generates information. In other words, we can initiate an investigation. What we do often is we initiate investigations and then bring in the agency that will have jurisdiction in that area and be working with that agency in terms of developing the grand jury investigation; but we are not limited to only acting on cases that come into the office after an agency has done an investigation. We ourselves can initiate the investigation, through the grand jury.

This proactive attitude is summarized in the observation of another U.S. Attorney that: "We don't sit back and wait for cases to walk in the door. We go out and make them."

However, use of grand juries is not sufficient to build important white-collar cases in a proactive fashion. Information and evidence are needed to begin building these cases. While in other prosecutions such information frequently comes from victims and witnesses, the white-collar crimes of white-collar persons usually are different: the complexity and diffuseness of the victimizations reduce the visibility of these crimes and, therefore, the likelihood of obtaining evidence from nonimplicated persons.[2] A U.S. Attorney explains the problem this way:

> . . . in these sort of activities, the only people with the information that you are going to have to convict are the participants. It is not like a bank robbery where innocent people watch and see and identify. The only way you can get these kinds of criminals is through information supplied by participants. You have to peel off the layers . . . and that is difficult. That is a burden that is tougher than the burden prosecutors in the past had to deal with.

The questions that follow are What is the exact nature of this burden? and Why is this burden so difficult to bear? Our interviews suggest that the nature of the burden is negotiation: the development of cooperative witnesses through plea negotiation. The process and problems involved are suggested in another segment of the above interview.

> The negotiation proceeds within the confines of reality. That is the advantage I think good defense counsel has. . . . He knows and can tell his client what is likely to happen, and how likely it is to happen. If we've got a weak case, we've got a weak hand. If you've got a really strong case, you hold four aces on the top and he doesn't have any choice. Well, he does have a choice. Some people just go down. They take their lumps and they don't want to talk. . . . One of the last chips we have is that we can say not only are we going to convict you and send you to prison and you aren't going to get anything. After that is all done, then we will put you in the grand jury and we will get the information anyway and you won't get any credit for it. Indeed at sentencing we will stand up and make a point of the fact that you refused to cooperate and that will be held against you and you will get even more time.

The proactive prosecution of white-collar persons and their white-collar crimes, therefore, comes down to the problem of how to get the leverage required to "turn witnesses," and the key to obtaining this leverage is to forge a connection between plea negotiations and concessions and coercion in sentencing. In other words, prosecutors must overcome the tendency toward loose coupling between most parts of the criminal justice system, establishing instead a direct connection between plea negotiations and sentencing decisions in white-collar cases. This can be accomplished in at least two ways: by carefully managing the severity of the charges in these cases, so that judges can use statutory guidelines in arriving at lenient sentences, and by getting judges to reward negotiated pleas directly. That such sentencing decisions *are generated* is suggested by the following observation of an Assistant U.S. Attorney in charge of a subsection responsible for the prosecution of official corruption in the district best known in our sample for its early emphasis on white-collar crime: "I would say most judges understand that in order to expose official corruption you do have to give some concessions to people who are involved. Again, because only those people who are involved know and can testify about it."[3] Depending on how extensive these understandings are, one implication of the connection we have drawn between negotiation and sentencing will be an overall tendency toward the lenient sentencing of white-collar persons convicted of white-collar crimes. In the remainder of this paper we use our quantitative data to examine evidence of this and related possibilities outlined in the perspective we have developed.

---

[2] Beyond this, even when such evidence might be obtained through record searches, accounting procedures, and the analysis of documents, the amounts of material and the methods of investigation are so costly in man-hours and resources, both to develop and to present in court, that such efforts rarely are undertaken.

THE PROSECUTION AND SENTENCING OF WHITE-COLLAR CRIME IN TEN FEDERAL DISTRICT COURTS

The quantitative data we will consider consist of 9,068 cases prosecuted, and 6,562 cases sentenced, in our ten district courts over a period beginning in 1974 and ending in 1977. These data were collected by the administrative office of United States Courts, and our use of the data is premised on an agreement not to identify individual districts in our analysis.[4] Before beginning this analysis, we must specify our operationalization of the concept of white-collar crime.

Although the term "white-collar crime" has gained currency in several languages and in popular thought, there is disagreement about its definition (see Geis and Meier, 1977). As indicated earlier, much of the problem involves the kinds of *crimes* and kinds of *people* involved. Our analysis is based on an operational definition that allows consideration of both the offender *and* the offense. We began with a listing of all offenses in the United States

---

[3] The federal law itself can be an effective means toward this end. For example, the Mail Fraud Statute and the Travel Act have been used with considerable "legal craftsmanship" to successfully prosecute important white-collar cases (see Henderson, 1977). An indication of the flexible way in which these statutes have been used to generate cooperation and achieve convictions is suggested by the following rather sardonic excerpt from a dissenting appeal court opinion. This appeal resulted from the successful prosecution (during the period of our study in what we later identify as a very proactive district) of a major bribery case.

> I conclude by depicting a scenario which I have little doubt approximates the facts of this prosecution. Federal officials, getting wind of a deal between . . . state legislators and the . . . industry, assign agents to investigate. In due course, immunity is promised to some of the involved legislators and company officials in return for their cooperation and testimony. Recording devices are placed on some of the immunized persons to obtain inculpating admissions from those who are the targets of the prosecution. Once the investigation is completed, consideration is then given to what federal offense, if any, has been committed. The Mail Fraud Statute? The Federal Travel Act? The investigation files are searched to find some mailings or evidence of interstate travel. The United States Attorney's office sifts through the mailings in the file and then constructs a legal theory in order that they may be used to form the basis for a charge of mail fraud. One fortuitous trip, totally incidental and unforeseen, by an unindicted coschemer forms the basis of the two travel-act counts. A conspiracy count is, of course, added. In this fashion, the Mail Fraud Statute and the Travel Act are subverted to purposes for which they were never intended. No longer are the mailings and travel considered essential or an integral part of the scheme; they are seen and used to obtain federal jurisdiction.

In the above case, the central "unindicted coschemer" was separately charged with one count of making a false statement on his Income Tax return (that is, the bribe), to which he pleaded guilty. The statutory maximum sentence for the latter offense was three years imprisonment, and this offender received one year on probation. The other legislators in this case were charged with mail fraud, conspiracy, and travel-act violations, exposing them to potential concurrent sentencing and a statutory maximum sentence of five years imprisonment on one count of mail fraud alone. All pleaded not guilty; one was acquitted, while the others received three-year prison sentences and fines. A remaining group of corporate executives was charged with the same offenses, pleaded guilty, and received one to two years' probation and fines. This case usefully illustrates the important role which plea and charge negotiation can play in a proactive district in the prosecution and sentencing of important white-collar cases.

[4] These data were collected with special provisions for quality control and comprehensiveness made possible through a mandate of the Speedy Trial Act of 1974 to evaluate the experimental bail reform program established under this Act. All but 88 cases (which came into the data set in 1974) are from the years 1975 through 1977. The provisions of the evaluation were that a population of cases was to be collected during this period. Our interviews in all ten districts indicated full cooperation in the fulfillment of this mandate.

Code that could plausibly be thought of as white-collar crimes.[5] We then refined this classification by asking U.S. Attorneys in the ten districts to approve or disapprove of the inclusion of offenses, asking each to identify offense codes that were almost always white-collar, sometimes white-collar, and almost never white-collar. Thirty-one offenses that elicited considerable consensus as white-collar crimes were retained,[6] and, for the purposes of this research, the other offenses were designated as common crimes. We proceeded by cross-classifying the dichotomy with two dichotomized measures of the offender's social standing: education (high school or less, and college or more) and income (less than $13,777, and $13,777 or more, per year, in 1974–1977 dollars). These are the most direct measures of social standing available in our data, and we have dichotomized them on the basis of Featherman and Hauser's (1978) recent replication of the work of Blau and Duncan (1967). Thus, our cut points correspond to the highest grouping of occupations considered in these studies. Analyses reported in this paper have been done separately for the education and income measures, with, as we will see partially in Table 1, substantially similar results. However, in deference to space limitations, we present only the results involving education beyond Table 1. Education was selected over income for two reasons: it allows us to consider women without reported incomes in a more meaningful manner, and it avoids the problem of correcting for a deflating dollar over the several-year period. The resulting cross-classification that forms a central part of our analysis includes the following four kinds of cases: the common crimes of the less educated; the common crimes of the college educated; the white-collar crimes of the less educated; and the white-collar crimes of the college educated. As indicated earlier, the latter type of case is of greatest interest to us because it is the "purest" form of white-collar crime we can identify and because we expect prosecution of this type of case to exhibit the most interesting variation across districts.

The first step in our analysis was to examine the distribution of prosecutions and dispositions for the four offender-offense combinations in all ten districts. What we found was a striking similarity in these distributions for nine of the ten districts. The tenth, which we call District C,

---

[5] The original listing was made available to the authors by Stanton Wheeler and John Cardascia and consists of 53 offenses abstracted from the Code.

[6] A short description follows of 27 of these offenses, with the Title number, Section number, and number of cases involving a college educated offender indicated in parentheses: trust, etc., in restraint of trade (15:1:51); bankruptcy—concealment of assets, false oaths and claims, bribery (18:152:1); bribery, graft, and conflicts of interest—bribery of public officials and witnesses (18:201:5); bribery, graft, and conflict of interest—salary of government officials and employees payable only by U.S. (18:209:1); bribery, graft, and conflict of interest—offer to procure appointed public office (18:210:1); claims and services in matters that affect government—conspiracy to defraud the government in respect to claims (18:286:1); claims and services in matters that affect the government—false or fraudulent claims (18:287:12); embezzlement and theft—accounting for public money (18:643:1); embezzlement and theft—custodians generally misusing public funds (18:648:1); embezzlement and theft—theft, embezzlement or misapplication by bank officers or employees (18:656:57); embezzlement and theft—lending, credit, and insurance institutions (18:657:6); embezzlement and theft—property mortgaged or pledged to farm credit agencies (18:658:1); embezzlement and theft—theft or embezzlement from employee benefit plan (18:664:1); fraud and false statements—statements or entries generally (18:1001:23); fraud and false statements—bank entries, reports, or false transactions (18:1005:2); fraud and false statements—federal crime institutions entries, reports, and transactions (18:1006:1); fraud and false statements—Department of Housing and Urban Development and Federal Housing Administration transactions (18:1010:2); fraud and false statements—Department of Housing and Urban Development transactions (18:1012:1); fraud and false statements—loan and credit applications generally, also renewals and discounts, crop insurance (18:1014:14); mail fraud—frauds and swindles (18:1341:56); mail fraud—fictitious name or address (18:1342:2); mail fraud—fraud by wire, radio, or telephone (18:1343:6); attempt to evade or defeat tax (26:7201:11); failing to file tax return (26:7203:28); fraud and false statements (26:7206:23); fiduciary responsibility of officers of labor organizations (29:501:1); fraudulent acceptance of payments—veteran's benefit (38:3502:6). Four additional offenses (18:2073; 26:7207; 26:7262; 49:322) were designated as white-collar by U.S. Attorneys in our interviews. However, these offenses did not result in convictions for college educated offenders in our data.

* Each cell of each cross-classification is percentaged first by row, second by column, and third in relation to the full cross-classification.

was distinguished by its disproportionate prosecution of white-collar persons involved in white-collar crimes. Table 1 presents the distribution of prosecutions and dispositions, by offender and offense, in District C as compared to the other nine districts.

Table 1 reveals that while 9.8% of the prosecutions and 11.7% of the convictions in District C include college educated persons involved in white-collar crimes, the respective figures for the remaining districts are 3.6% (ranging from 2.7% to 4.5%) and 4% (ranging from 2.4% to 5.4%). When income is used as the measure of social standing in Table 1, the disparity in convictions between District C and the other districts increases slightly to 12.1% as compared with 2.4%. At a minimum, then, District C prosecutes and convicts more than twice the proportionate number of white-collar persons for white-collar crimes as do the other districts. Thus, although the caseloads of none of the districts are overcrowded with the latter types of cases, both in prosecutions and convictions, District C is clearly the deviant case. Yet another way of making this point is to indicate that, while District C prosecutes only 9.9% of the cases handled in all ten districts, it prosecutes 22.9% of the white-collar cases involving college educated persons. The respective conviction figures are 10.6% and 25.8%, and 10.6% and 37.1% when income replaces education as the measure of social standing. These data suggest that whether education or income is used as the measure of social standing, District C has followed a uniquely proactive pattern in its prosecution of white-collar crime.[7]

Returning to Table 1, we should also note that in none of the districts does the prosecution of white-collar crime predominately involve what might conventionally be regarded as white-collar persons. Approximately half of the white-collar crimes prosecuted (48.1%) and convicted (49.1%) in District C involve college educated persons, compared to about one-third in the other districts (34.6%; 34.4%). A similar pattern prevails in the part of Table 1 that replaces education with income. Thus, although District C again demonstrates a more proactive emphasis on the white-collar crimes of white-collar persons, this emphasis is by no means exclusive. This finding is consistent with the observation of Katz (1979:433) that "There are relatively few crimes that can be committed only by those in white-collar occupations" and the observation of Geis (1974:284) that "white collar crimes can be committed by persons in all social classes." Federal prosecutors not only believe, but also act on, this assumption—pursuing, for example, large numbers of bank clerks for small-scale embezzlements and less educated citizens for relatively small-scale income tax violations (see Long, 1979). The other side of this situation is that college educated persons, also, of course, are prosecuted and convicted for common crimes. In fact, there is rather striking consistency in the finding that approximately 16% of the prosecutions as well as of convictions for common crimes, in District C as well as in other districts, involve college educated persons. Although the figures for income are smaller (10.2% and 7.1%), there is consistency here as well. This consistency is in contrast to the variation we find in the prosecution and conviction of white-collar persons involved in white-collar crimes.

We have also included in Table 1 mean sentence scores (see Table 2 for the scale used) for the various offender-offense groupings. Several things are apparent in these figures.

First, although there is a general tendency across districts for white-collar crimes to result in lighter sentences than common crimes, the disparities involved are greater in District C than in the other districts.

Second, in District C, whether education or income is the measure of social standing, white-collar persons prosecuted for white-collar crimes receive the most lenient sentences. (By contrast, in the other districts, the lightest mean sentences are received by less educated and lower income persons prosecuted for white-collar crimes.)

Third, with the exception of instances when income is considered in District C, the common crimes of common criminals result in the most severe sentences.

Fourth, the largest disparity in mean sentences reported in Table 1 is within District C, and it involves the common crimes of the less educated ($\overline{X} = 8.04$) and the white-collar crimes of the college educated ($\overline{X} = 3.49$).

Fifth, when comparisons are made between the same offender-offense groupings in District C and the remaining districts, the most consistent disparity observed across the districts is in the mean sentences received by college educated white-collar criminals ($\bar{X}$ = 3.49 and 4.64) and high income white-collar criminals ($\bar{X}$ = 3.55 and 4.98). A possible implication of these findings, consistent with the perspective outlined earlier in this paper, is that the proactive prosecution of white-collar crime in District C results in more lenient sentencing, particularly for white-collar persons. However, before inferences are drawn from these findings, it is necessary to consider a number of other relevant variables. We do this in the multivariate analyses presented in following sections of this article.

---

[7] District C is uniquely proactive in the sense that, by the measures applied, it is the *most* proactive district in our data. This said, we should also note that while the *volume* of white-collar cases prosecuted and convicted in District C is not dramatic, the reallocation of resources required to pursue even this number of cases is probably substantial. Our point is simply that white-collar cases require a disproportionate investment of resources and that, therefore, the doubling of the proportionate number of prosecutions and convictions (albeit still not large) in District C is probably a more dramatic difference than it might otherwise seem. This point is addressed again, in a somewhat different way, in the conclusion to this article.

Finally, although we might have expected more variation across districts in our data, we should note that the unique position of District C is not surprising. This is the District in our data set that is best known for its early emphasis on the prosecution of white-collar crime. This tradition was established most visibly by a U.S. Attorney who made the proactive pursuit of white-collar crime and political corruption a focal point of his work. The impression formed in our interviews, in the public statements of officials in the Department of Justice, and in recent highly publicized cases being pursued in the federal courts is that this is a style of administration that is going to become more prominent in the federal system. Thus, the following comparative analysis of sentencing patterns in District C and the other nine districts may be important to not only the debate on status characteristics and sentencing but to our understanding of the shape of things to come, as well.

METHODS AND MEASUREMENT

Table 2 presents the variables and their codings to be considered in this analysis. Variables are included on the basis of the perspective outlined above, prior research (e.g., Hagan, 1974; Chiricos and Waldo, 1975; Burke and Turk, 1975; Bernstein et al., 1977; Nagel, 1980; Swigert and Farrell, 1977), concerns for multicollinearity, and suggestions arising from our interviews. Thus, we began with a traditional list of variables that includes prior adult felony convictions, statutory seriousness of the offense, number of charges for which the defendant was convicted, ethnicity, sex, age, and employment status; then, we added to these consideration of whether or not the defendant was undergoing treatment for physical and/or mental illness. Our interviews suggested that the latter two variables might be particularly relevant for white-collar defendants. In addition, our sensitivity to the impact of prior processing decisions on sentencing suggested the inclusion of bail status (ordinally ranked on the basis of our interviews and on an evaluation of the fiscal and personal constraints involved), whether the defendant pleaded guilty, and a consideration of charge reductions. Since multiple defendants are common in white-collar cases, we also included a measure of their presence in our analysis. Several of the variables introduced thus far have particular significance for this study and are discussed further, here.

For example, statutory seriousness is an important variable to the perspective developed in this paper. This variable is measured in terms of the maximum prison sentence provided in the United States Code for the charge initially placed against the offender (charge reductions are considered below). Since white-collar crimes generally are assumed to carry lower statutory maximums then common crimes,[8] and because prosecutors can also use their discretion in selecting the statutory seriousness of the charge, the statutory seriousness variable may be expected to form a particularly important link in the prosecution and sentencing of white-collar persons for white-collar crimes.

From the perspective on white-collar crime outlined earlier, the offender's plea is also expected to be a very significant link between prosecution and sentencing. At minimum, a guilty plea in such a case saves the resources otherwise required to establish guilt in court. Since important white-collar cases are characteristically complex, this is often a considerable savings. Beyond this, many guilty pleas in-

---

[8] Consistent with this assumption, there is a correlation of −.14 in our data between statutory seriousness and those white-collar crimes involving college educated persons.

volve the cooperation of the offender in building a case against others. Thus, in these types of white-collar cases, we expect the plea entered to have a notable effect on the sentence imposed—particularly in a district where the prosecution of a large number of these cases is made a priority. This coupling between prosecutorial and judicial subsystems may be an important source of the differential sentencing of white-collar offenders. In this data set, guilty pleas are coded 1, pleas of innocence −1.

Charge reductions may also influence sentence severity, as a way of rewarding cooperation in white-collar cases. Charge reductions are coded from −3 to 3 in terms of all six possible movements up and down in severity among petty offense, misdemeanor, and felony. No change is coded 0. However, it should be noted that the possibilities for charge reductions in the federal courts are not as great as in the state courts:

> The reason for this difference is that state criminal codes include lesser offenses to which charges frequently can be reduced, whereas the federal criminal code typically does not. . . . A result is more explicit recourse to discussions of sentencing and related sanctions. (Hagan and Bernstein, 1979:470)

The implication is that in the federal system the plea itself may be a more potent variable than the charge reduction.

The next three variables in Table 2 involve the offender and offense components of white-collar crime. The three variables considered derive from a dummy coding (see Kerlinger and Pedhazur, 1973) of our earlier cross-classification of the offender's education and offense. Each of these variables, when included in the regression analyses that follow, yield a coefficient that represents the difference in sentence for cases classified as the specified offender-offense grouping compared to those that are classified as a designated "reference category." For the purposes of our analyses, we have designated the common crimes of less educated persons as our reference category. This will allow us to estimate an effect parameter for each of our offender-offense groupings, compared to the reference category, with all other variables in the regression equation taken into account. As an example, we will be able to examine whether the disparity—observed earlier in the sentences received by college educated white-collar criminals, as compared to less educated common criminals—persists when the other independent variables just discussed are taken into account.

The last variable in Table 2, sentence severity, is our dependent variable. The coding of this variable derives from the efforts of Tiffany et al. (1975) to devise an approximate interval scale of the severity of different sentencing options. Minimal revisions in this scale derive from our interviews and are intended to reflect further gradations in the severity of sentences imposed.

Our analysis of the variables described above is based on conventional regression procedures. The strategy followed is to focus first on District C, in comparison to all other districts. Our purpose is to examine comparatively the consequences of the proactive prosecution of white-collar crime in District C. The perspective developed earlier suggests that the proactive prosecution of white-collar persons for their white-collar crimes requires concessions in sentencing, and it is this possibility that we first consider. We then go on to examine more specifically the factors leading to severe or lenient sentencing for each of the four offender-offense combinations in District C, as compared to the other nine districts. This second phase of the analysis explores which of the other independent variables may contribute to the expected differential sentencing of white-collar offenders in District C, as compared to the other districts. The perspective developed earlier suggests that concessions in the sentencing of these cases may follow from lenient initial charges, the rewarding of guilty pleas, and, possibly, charge reductions. These are the factors judged important in tightening the connection between the prosecutorial and judicial subsystems, thereby circumventing the obstacles posed to proactive prosecution in a loosely coupled system. Furthermore, if this tightening of connections between the prosecutorial and judicial subsystems does occur, we should also expect an increase in our ability to explain sentencing decisions in these types of cases—a consequence of a recognized common goal in a system otherwise characterized by divergent subsystem concerns. We also examine these expectations in the second phase of our analysis.

We should note that all comparisons undertaken in the remainder of this article effectively involve populations or subpopulations. That is, we are not dealing with samples, but, rather, with the full volume of cases involved in any given comparison (see footnote 4). Nonetheless, we report tests of significance in the tables that follow. These tests can be interpreted as checks on other kinds of random errors (for example, random measurement error). Our approach is to consider effects statistically significant at the .05 level and better, with betas larger than .10. Although there has been some debate as to whether standardized or unstandardized regression coefficients are more appropriate for the types of comparisons made in this paper, the more recent judgment is that both have their place (Hargens, 1976). Therefore, both coefficients are reported in our tables. However, there are some instances where unstandardized coefficients will be more suitable for our purposes. For example, the standardization of dummy variable coefficients can be misleading, particularly when the distributions of these variables are skewed (Cohen and Cohen, 1975:184). Therefore, where dummy variables are involved, unstandardized coefficients will be emphasized in the analysis that follows.

THE ANALYSIS

The results of the first part of our analysis are presented in Table 3. This table reports the results of regressing sentence severity on our independent variables separately in District C, the proactive district, and in the remaining districts. Our primary interest in these regressions is to see if—other variables held constant—the sentencing of white-collar persons for their white-collar crimes varies among these districts. The results presented in Table III indicate that this group is indeed sentenced differently in District C than in the remaining districts. A comparison of unstandardized regression coefficients reveals that while in the remaining districts college educated white-collar criminals do *not* receive significantly more lenient sentences than the reference category (less educated common criminals), in District C the former group *does* receive sentences that in comparison to the latter group are nearly three points lower (r = −.21; b = −2.72; B = −.16) on the sentence severity scale. However, what we did not anticipate is that less educated white-collar criminals experience a nearly identical leniency (r = −.18; b = −2.70; B = −.16) in District C that, again, is not paralleled in the remaining districts. College and less educated common criminals are not dramatically differentiated in the sentences they receive in either District C or the remaining districts. Overall, then, Table 3 provides provisional support for the perspective we have proposed: with a variety of other important variables held constant, our proactive distirct does grant lenient sentences to college educated

white-collar criminals, while the remaining districts do not. However, this same pattern is apparent for less educated white-collar criminals. Thus, the issue that remains is whether these two offender-offense groupings actually differ in ways consistent with the perspective we have proposed. This issue is pursued in the next phase of our analysis.

Tables 4 and 5 present the results of regressing sentence severity on our independent variables within each of the four offender-offense groupings, first in District C, then in the remaining districts. We note first in these tables that, consistent with the perspective outlined earlier, the highest explained variance involves the sentencing of college educated white-collar offenders in District C ($R^2 = .39$). We take this as one indication of a tightening of connections in an otherwise loosely coupled system. Beyond this, however, we are anxious to determine *where* such a tightening in subsystem op-

erations may occur. Thus, our next interest is in comparing the effects of our independent variables on sentence severity, particularly in cases of college and less educated white-collar offenders. Comparison of the latter offender-offense groupings will help to determine whether the lenient sentencing observed above for both of these groupings in District C follows from similar or different types of considerations.

Within District C, and in relation to the remaining districts, such comparisons reveal very different patterns of effects. For example, we find in Table 4 that, consistent with our perspective, in District C statutory seriousness (the seriousness of the initial charge) has the biggest effect on the severity of the sentences received by college educated white-collar defendants (B= .42, p= .003). In contrast, the effects of this variable for the comparable cases in Table 5, and for the cases of less educated white-collar criminals in Table 4, are negligible (B = .02 and .09).

To extend our understanding of this rather striking difference, we generated the frequency distributions of statutory seriousness in both District C and the remaining districts. These distributions are presented in Table 6. What we find is that, although this variable has approximately the same standard deviation in District C (s = 5.90) and in the other districts (s = 5.79), the difference between these distributions is nonetheless dramatic. In District C, the modal initial charge carries a maximum sentence of one year in prison; in the remaining districts, the modal initial charge carries a maximum sentence of five years. Beyond this, both distributions tend to be bimodal: each has a concentration of charges in the one- and five-year categories. The difference is that District C has a bigger concentration of cases toward the nonserious end of the continuum, while the remaining districts have their heaviest concentration of cases more toward the serious end. The bimodal character of these distributions is consistent with our suggestion that, to successfully build the evidence necessary to get convictions in major white-collar cases, it is necessary to offer concessions in other potentially serious cases. What is most interesting from our perspective, however, is that this pattern is particularly pronounced in District C, where white-collar crime has been pursued in a very proactive fashion.

Table 6. Frequency Distributions of Statutory Seriousness in District C and the Remaining Districts

Maximum No. of Years	District C No.	District C %	Remaining Districts No.	Remaining Districts %
1	49	60.5	31	13.3
2	2	2.5	15	6.4
3	5	6.2	25	10.7
5	24	29.2	156	67.0
10	1	1.2	2	1.0
15	0	0.0	4	1.7
	$\bar{X}=6.74$		$\bar{X}=7.87$	
	s=5.90		s=5.79	

Also consistent with our perspective is the effect of the next most influential variable, the plea, in the sentencing of college educated white-collar criminals in District C. Those who plead guilty in District C (b = −1.27, p = .028) are more likely to get lenient sentences, while no similar significant effect (b= .12) exists in the remaining districts, or for less educated white-collar criminals in District C (b = −.26). From our perspective, the implication is that prosecutors in the proactive district are successful in getting judges to reward and punish the cooperativeness of college educated white-collar offenders. As expected, then, the two most important variables explaining the tendency in District C to sanction more leniently college educated white-collar criminals are their pleas and the initial charges placed against them. We will also discuss a quite different pattern that is apparent in cases of less educated white-collar offenders.

One other variable, charge reduction, is noteworthy for its *absence* of effect on the sentencing of white-collar cases in all districts. As indicated earlier in our discussion, this may be a result of the limited opportunities for charge reduction in the federal system. The effect of this situation may be to relegate much prosecutorial negotiation to less visible stages that precede initial charging decisions. We have already noted that, in District C, the statutory seriousness of the initial charge has its most pronounced effect for college educated white-collar criminals. In contrast, in the more reactive remaining districts statutory seriousness has a prominent effect in the cases of less educated common criminals. The volume of these cases and the influence of this variable may reflect the tendency of these more reactive districts to balance the needs and wishes of the enforcement agencies that focus on more traditional crimes.

We turn now to a consideration of a very different pattern of effects apparent in the sentencing of less educated white-collar criminals in both District C and the remaining districts. At this point it may be useful to recall that these cases consist in large part of income tax violations and bank clerk embezzlements. Since we did not anticipate the lenient treatment that these offenders receive in District C, our interpretation of these effects is, clearly, ad hoc. Nonetheless, we will begin by offering one suggestion as to why college and less educated white-collar crininals receive a similar type of leniency in District C. This suggestion is no more complicated than the observation that similar types of charges are placed against these offenders and that, once concessions are granted to the higher status white-collar offenders, it may be difficult not to grant them more generally, at least where similar statutory provisions are involved. In more familiar terms, a privilege once granted is difficult to deny later. Beyond this, it seems plausible to interpret the pattern of effects for this group in District C in terms of a compliance, as much as a punishment, model. Thus, the two most prominent findings for this group in District C are that being employed results in more lenient sentences (B = –.24), while being under psychiatric treatment results in more severe sentences (B = .27). The former finding applies only in District C, while the latter finding applies in the remaining districts as well. This second counter-intuitive finding apparently results from a provision in the federal code which allows offenders thought mentally ill to be institutionalized for a 90-day "psychiatric study," and, then, to be resentenced at the end of this period. Alternatively, the finding in District C of greater leniency for those offenders who remain employed probably reflects a willingness to let these offenders work out arrangements to make restitution in lieu of more severe punishments. The concern, at least in District C, would seem to be as much with remedying the behavior as with punishing it. In any case, we clearly have demonstrated that the differential leniency experienced by college and less educated white-collar offenders involves some very different considerations. We take this as support for our argument that the lenient sentencing of white-collar persons for their white-collar crimes derives from a set of circumstances that distinguish the proactive prosecution of this type of case.

A final finding, consistent across all districts, merits our attention. This finding is that bail status has a substantial impact on sentencing that is particularly consistent for common criminals (the B's range from .24 to .39). The implication of this finding is that negative bail decisions have particularly disadvantaging consequences for all kinds of common criminals. This finding is not new, but it is nonetheless interesting to find that it holds in the federal courts, bound by the Federal Bail Reform Act, as well as in the state courts (see Bernstein et al., 1977).

CONCLUSIONS

Gilbert Geis (1974) has made two important points about the study of white-collar crime. The first point is that relatively few original pieces of research have been published on white-collar crime during the past two decades (see also Wheeler, 1976). The second point is that further study of white-collar crime is important because it can tell us a great deal about the way power is exercised in our society. To these important points, we would add another: examination of the prosecution and sentencing of white-collar crime can tell us much about how the social organization of a particular type of crime can influence the way it is controlled. In turn, this type of understanding may do much to enlighten a long tradition of research on status characteristics and sentencing.

We noted in the beginning of our discussion that the above type of sentencing research has suffered from inadequate data. The inadequacy of these data is less the failing of social researchers than it is a failure of the system to prosecute and sentence any large volume of important white-collar cases. The infrequency of these prosecutions derives not only from the power of the persons involved but also from the manner in which these criminal activities are organized. Most *common crime* involves *victims or witnesses* and is pursued *reactively* in response to their complaints. In contrast, most *white-collar crime* involving *white-collar persons* is characterized by a diffuseness of victimization and an absence of unimplicated witnesses. As a result, a *proactive* organization of legal resources usually is required to seek out and build these white-collar cases. Since, frequently, only the participants in these criminal events can provide the information necessary to build successful cases, prosecutorial negotiation becomes a key part of the proactive prosecution of these cases. Furthermore, to make this negotiation work, a connection must be forged between the prosecutorial and judicial subsystems, such that the promises and concessions offered white-collar offenders are actually confirmed at sentencing. We have argued that this type of connection is the exception more than the rule in a criminal justice process we have called a loosely coupled system.

The overall implication of the organizational relationships we have described is, of course, that white-collar persons will receive lenient sentences for their white-collar crimes. However, it is important to note that this disparity might be expected only where the prosecution of white-collar cases is proactive enough to generate a large volume of cases. This is, of course, exactly what we found in our data: college educated white-collar criminals received more-lenient sentences only in District C, our most proactive district.

What we did not anticipate on the basis of the perspective developed in this paper is that less educated white-collar criminals would also receive lenient sentences in District C. A question that follows from this finding is whether the white-collar crimes of more-highly educated persons are actually handled in the unique way our perspective suggests. However, our subsequent analysis of cases falling within the separate offender-offense groupings confirmed that quite different factors were involved in the sentencing of each, and that college educated white-collar persons indeed *were* sentenced on the basis of several of the considerations emphasized by our perspective. In an ad hoc fashion, we speculated that one reason less educated white-collar criminals may also receive lenient sentences in District C is because they are charged under similar statutes: once these statutes are used in a lenient fashion, it may be difficult to deny their wider application. This interpretation is consistent with our earlier findings that at a bivariate level it is college educated white-collar criminals who actually receive the *most*-lenient sentences in District C, *and* that it is a higher concentration of this latter type of case in District C that makes it most unique. Nonetheless, we take these findings collectively as indicating the importance of further research on the ways in which types of persons, crimes, and control strategies interact.

More generally, our findings have theoretical—as well as policy—implications. They suggest, on the one hand, why previous research has rarely found relationships between status characteristics and sentencing to be large: as critics have suggested, there simply may not have been enough variation in the types of offenders and offenses studied to generate such relationships. This does not make the prior research wrong; it simply makes it representative of the types of courts studied. On the other hand, the modest relationship reported in this study, for District C ($r = .21$; $b = -2.72$; $B = -.16$), may be all the more striking given that—even in this proactive district—college educated white-collar criminals make up only 11.7% of the population sentenced (cf. Cohen and Cohen, 1975:178). The interesting possibility this point raises is that the observed relationship may grow as the volume of cases (or, in other words, the level of proactive prosecution) increases. Put differently, there may be an inverse relationship between the volume of white-collar convictions and the severity of white-collar sentences. At this point, concerns about deterrence and equal treatment may come into conflict: convictions may be enough to deter some white-collar crime, but they are not enough to establish a sense of parity in the treatment of white-collar and common crime.

These concerns are aggravated by the further findings that the lenient sentencing of college educated white-collar criminals in our proactive district apparently is associated with the less-serious charges placed against these offenders and with a rewarding of their guilty pleas. The sense is of a style of prosecution that gives preferential treatment to highly educated white-collar offenders. That this may be what is required to successfully prosecute important white-collar cases is an uncomfortable paradox that policy makers as well as theorists will do well to consider.

We should also note other less central, but no less significant, findings of this research. Among the less educated white-collar criminals in District C, we found that employment and mental illness were prominent factors in determining sentences: employment led to leniency, while treatment for mental illness resulted in severity. The latter finding was explained in terms of a federal provision that allows offenders thought mentally ill to be placed in penal institutions for psychiatric study; the former finding probably reflects a willingness to allow offenders in this grouping who are still employed to work out arrangements for making restitution. We suggested that in cases of less educated white-collar criminals the concern may be as much with obtaining compliance as with imposing punishment. Finally, quite apart from the preceding group of offenders, we also found that bail decisions have pronounced effects on the sentencing of common criminals. A theoretical implication of this finding is that bail outcomes may constitute one of the most salient kinds of legal labelling that common criminals experience.

The findings of this research do not encourage a reliance on law reform as an effective means of reducing sentence disparities. Notwithstanding important reforms in the federal bail system, we have found that bail decisions still exert a persistent impact on the severity of the sentences received by common criminals. Even more significantly, however, we suggest that the independence and variability of prosecutors demonstrated in this study is a neglected consideration which should reduce widespread expectations that recodification of the criminal law, sentencing guidelines, and reform or elimination of parole will eliminate sentencing disparities. Such reforms can readily be counteracted by shifts in prosecutorial policies on charging and plea bargaining and this seems particularly likely in an area as socially and legally sensitive as white-collar crime. The differential sentencing of white-collar offenders is a social as well as a legal problem.

TESTING A STRUCTURAL THEORY OF CORPORATE COOPTATION: INTERORGANIZATIONAL DIRECTORATE TIES AS A STRATEGY FOR AVOIDING MARKET CONSTRAINTS ON PROFITS*

RONALD S. BURT

American Sociological Review 1980, Vol. 45 (October):821–841

Moving away from description of directorate ties as a cooptive device, we test a theory explicitly predicting cooptive uses of corporate directorates from the structure of the market in which firms operate. The theory is based on a network model of structural autonomy. It takes as exogenous information the sales and purchase transactions between establishments in sectors of the economy, locates those sectors most constraining pricing discretion within each sector, then predicts where establishments should be connected by interorganizational relations if such relations are intended to coopt market constraints. Using data on interorganizational relations as directorate ties (establishments connected through corporate boards by ownership, direct interlocking, and/or indirect financial interlocking) in the 1967 American economy, we find the theory's predictions to be accurate. Each of the three types of directorate ties tends to occur where there is market constraint and tends not to occur in the absence of constraint. Further, the three types of ties are coordinated as multiplex directorate ties. Where establishments in one sector constrain those in another, there is a strong tendency for all three types of directorate ties to exist between the two sectors. Where there is no such constraint, all three tend to be absent. Support is weaker for intrasector in comparison to intersector cooptation via directorate ties. Whatever the cooptive intent of the directorate ties described, they are patterned as if they were intended to coopt market constraints on corporate pricing discretion.

If two firms have interlocked directorates (one or more persons sitting on the board of directors for both firms) and such a connection allows either firm to coopt the ostensibly competitive market transactions the firms have with one another, then the presence of directorate ties on a large scale within an economy is evidence of an integrated economic elite. Wary of such connections in the United States, social scientists have devoted years of research to describing the cooptive potential of the corporate board. A summary empirical generalization from this research is the following: There is extensive corporate interlocking in the United States, particularly in urban corporate centers such as New York, Chicago or Los Angeles, and those firms most likely to be involved in it are large firms operating in capital intensive industries where the firm is controlled by diffuse interest groups (for comprehensive literature review, see Aldrich and Pfeffer, 1976; Aldrich, 1979). Measuring firm size as dollars of assets or annual sales, a ubiquitous finding is that a firm's size is positively correlated with the number of different corporations represented on the firm's board of directors (Warner and Unwalla, 1967; Dooley, 1969; Pfeffer, 1972; Allen, 1974). Also, there is a positive correlation between a firm's capital

Writing and analysis for this discussion were accomplished while the senior author was on a leave of absence spent in the Department of Sociology, SUNY at Albany. The excellent research facilities made available there by R. Farrell, R. Hall, and N. Lin were greatly appreciated. As part of the ongoing work under the Project in Structural Analysis at the Survey Research Center, UC at Berkeley, this research was supported by a grant from the National Science Foundation (SOC77-22938). N. Anderson and M. Lundgren provided able research assistance in coding data on directors of firms and corporate establishments. An anonymous reviewer for this journal greatly improved the discussion by pointing out ambiguities in the initial manuscript.

requirements and its tendency to represent other firms on its board of directors.[1] Among the many firms represented on a typical board of directors, moreover, there is usually a representative from a major bank in the same geographical region as the firm itself (Warner and Unwalla, 1967; Dooley, 1969; Levine, 1972; Pfeffer, 1972; Allen, 1974; 1978; Bearden et al., 1975; Mariolis, 1975; Sonquist and Koenig, 1975; and for replication in Great Britain and the Netherlands respectively, see Stanworth and Giddens, 1975; Mokken and Stokman, 1979). Thirdly, few other firms are represented on a board dominated by a single interest group. Two kinds of groups in particular have been researched, management and kinship. The thesis advanced by Berle and Means (1932), and supported by subsequent research (Larner, 1970; Allen, 1976), is that corporate "management" in the guise of the board of directors and senior corporate officers has come to power as a result of the diffusion of shares among so many owners that individual owners no longer exercise control over the corporate use of their capital. Contradicting this management control thesis is research demonstrating the continued existence of powerful families as kinship groups whose extensive stock holdings in large corporations perpetuate their ultimate corporate control (Burch, 1972; Zeitlin, 1974; 1976). Whatever the assumed basis for directors reaching decisions and maintaining their positions as directors, empirical research on the question of corporate control has documented a negative correlation between the tendency for other firms to be represented on a corporate directorate and the percentage of directors who are officers in the corporation (Dooley, 1969; Pfeffer, 1972) as well as the extent to which a single family owns a controlling share of the corporation's stock (Allen, 1976).

These findings can be interpreted as support for an argument that directorates are used to coopt market constraints. The larger a firm is, then the more impact its actions have on other organizations and, accordingly, the more the firm needs representatives who can integrate and legitimate the firm in its external environment (cf. Dooley, 1969:316; Pfeffer, 1972:223; Allen, 1974:395). Arguing for a cooptive interpretation of capital intensive firms representing financial firms on their directorates, Allen (1974:395) suggests that capital is a ". . . very generalized resource with a very dispersed demand from such economic organizations as corporations" (cf. Pfeffer, 1972:224). Thirdly, the negative correlation between concentration of corporate control and interlocking can be interpreted in terms of cooptation. The more that control of a firm is concentrated in the hands of a single group (management or family), then the greater is the loss of control incurred with the addition of a single outside group on the firm's board. Selznick's analysis of the TVA demonstrates that cooptation can backfire. When the TVA brought representatives of local organizations into its own decision-making structure, the TVA was forced into some actions more beneficial to the local organizations than to the TVA (see Selznick, 1949:113–4, 145–53, 205–13, 217, 259–61), although the long-term benefit to the TVA of avoiding local conflicts is not to be belittled. Where control of a corporation is already dispersed such that each interest group has little control over decisions, on the other hand, the addition of yet another voice on the board entails little loss of control for each group currently on the board. In order to maintain a decision-making capacity unimpaired by the competitive interests of their corporate environment, therefore, a dominant kinship or management group in a directorate would be expected to oppose extensive interlocking with other firms (cf. Dooley, 1969:322; Pfeffer, 1972:224). In Zald's (1969) terms, concentration of corporate control in a kinship or management group results in the firm's board serving an internal control function rather than an external representation function.

---

[1] This correlation is observed in a comparison of financial versus nonfinancial firms and Pfeffer (1972:224) reports a positive correlation between interlocking and a firm's capital needs as the ratio of dollars of debt over dollars of equity. Among nonfinancial firms, however, the correlation is negative. Allen (1974:400) reports a negative correlation between interlocking and a firm's capital needs measured as the ratio of dollars of assets over number of employees. Using the traditional capital output ratio to measure capital intensiveness (dollars of assets over dollars of sales, e.g., Lustgarten, 1975), Burt (1980b) also reports low negative correlations between interlocking and capital requirements. In addition, however, the analysis of multiplexity reveals a significant tendency for capital intensive (manufacturing) firms to have a complete multiplex directorate tie to finance; such firms own a finance firm as a subsidiary (Burt, 1980b:Table 8). This could explain why capital intensive firms need not interlock more than noncapital intensive firms; the former own their own establishment in the finance sector.

These cooptively interpreted findings have yet to directly address the connection between market structure and cooptive interorganizational structure. Discussing the cooptive uses of directorates makes intuitive sense. Indeed, interlocking directorates would not be considered a threat to competition between establishments unless such linkages were potentially cooptive. By itself, however, interpreting interlocking directorates as cooptive devices does not advance theoretical understanding of interlocking so much as it provides a sociological label for interlocking. Like instinct theories of action in which a person's behaviors are explained by attributing to the person an instinct for those behaviors, cooptation is a rationalization for action without a specification of parameters for action. In other words, there is no theory predicting when an interlocking directorate between two organizations is not cooptive. Accordingly, there is no method of rejecting an argument interpreting such connections as a cooptive device. What is known is that some types of firms use their directorates in what can be interpreted as a cooptive manner. What is not known is whether these ostensibly cooptive uses of directorates are patterned by market constraints so as to reduce competition between firms or whether there are merely some types of firms that engage in representing the corporate environment on their boards of directors.

Our purpose here is to use a network model of constraint to predict where directorate ties should, and should not, occur, if they are intended to coopt market constraints on profits. We demonstrate that three types of such ties are patterned by market constraint. They occur together in the presence of market constraint and tend not to occur in its absence. We conclude that, whatever substantive meaning is given to interlock ties, they are patterned as if they were being used cooptively.

THEORY

We employ a network model of "structural autonomy" discussed in detail elsewhere (Burt, 1980a; 1981:chap. 6). The model takes the patterns of relations among occupants of each status in a system as input and predicts the relative freedom the status offers within the system as well as the extent to which that freedom is constrained by role relations with each other status. In a sentence, the occupants of a status enjoy high structural autonomy within their system (i.e., have an ability to pursue their interests without constraint within the system) to the extent that their relational patterns ensure low competition with one another while simultaneously ensuring high competition among the nonoccupant actors with whom they interact. Their structural autonomy is severely constrained by their relations with occupants of a particular other status to the extent that they have relations with occupants of that status only and those occupants are perfectly centralized so as to collectively pursue their own interests. When this constraint occurs, occupants of the first status are expected to establish informal relations with occupants of the second status so as to coopt the sources of constraint on their autonomy.

A slight indulgence in algebra greatly clarifies these ideas. The basis for interstatus constraint is given by the following term expressing the constraint relations between occupants of statuses S_i and S_j pose for the occupants of status S_j:[2]

---

[2] The structural autonomy of occupying S_j, a_j, is then given as a function of these coefficients; $a_j = \beta_0 y_j + \beta_g X_j + \beta_x (y_j - \bar{y}) (\bar{X} - X_j)$, where $X_j = \Sigma_i x_{ji}$ for $j \neq i$, the positive effect of oligopoly on autonomy is given by β_0 and the constraining effect of relations with other status groups is given by β_x which is negative (cf. Burt, 1980a:Eq. 1; 1981a:Eq. 6.2b). This equation can be disaggregated to estimate the contribution relations between occupants of S_i and S_j make to the structural autonomy of S_j's occupants;

$$x_{ji} = [(z_{ji}/\Sigma_q z_{jq})^2 + (z_{ij}/\Sigma_q z_{qj})^2]y_i, \qquad (1)$$

where z_{ji} is the strength of the relation from S_j to S_i and y_i measures the extent to which occupants of S_i constitute an oligopoly in the sense that their decision making is centralized, enabling them to act as a single body to further their collective interests—at the potential expense of actors occupying S_j. If occupants of status S_j have relations only with occupants of S_i, then the bracketed term of the above equation equals 2. If they have no relations with the occupants of S_i, then the term equals 0 (specifically, $x_{ji} = z_{ji} = z_{ij} = 0$). In other words, x_{ji} is high to the extent that two things occur simultaneously: (1) occupants of S_j have relations only with occupants of S_i, and (2) the occupants of S_i are perfectly centralized (whereupon y_i equals its maximum value arbitrarily set at 1.0). Status S_j offers its occupants structural autonomy within their system to the extent that y_j is high and all x_{ji} are close to 0. A high value of x_{ji} indicates that status S_i poses a constraint for the autonomy of S_j's occupants. If some potentially cooptive type of relationship is being used within the system to eliminate these constraints, then a strong cooptive relation from status S_j to status S_i, call it w_{ji}, should be observed when x_{ji} is high, and should not be observed when x_{ji} is 0.

These simple ideas have been used to describe market constraints on corporate profits. An economy can be discussed as a network of interorganizational market transactions, sales to consumers and purchases from suppliers. The division of labor ensures considerable redundancy in such a network. Establishments producing similar types of commodities have similar relations from other establishments (i.e., will require similar proportions of commodities as inputs from suppliers) and to other establishments (i.e., will offer similar types of commodities as outputs to consumers). As commonly discussed in economics, these establishments producing similar goods fall into a single "sector" of the economy. The sales and purchase transactions can be aggregated into intersector relations since establishments within a sector have similar tendencies to purchase inputs from each sector as a supplier and have similar tendencies to sell outputs to each sector as a consumer. The resulting aggregate representation of interorganizational relations as intersector relations is discussed as an input-output table containing dollar flow coefficients, z_{ji} being the millions of dollars of sales by establishments in sector J to those in sector I (e.g., Leontief, 1966). In terms of the developments in network analysis upon which Burt (1980a) builds a theory of constraint, the fact that establishments producing similar goods have similar patterns of market relations with economic sectors means that the establishments are structurally equivalent within the economic market. The "sector" of an input-output table corresponds to the "status" as a jointly occupied network position in a density table (e.g., Burt, 1976; 1977; 1980c). Given data on the dollar flow coefficients among sectors of an economy and the extent to which establishments within a sector can act collectively as an oligopoly, therefore, the structural theory of constraint can predict the relative freedom enjoyed in each sector and the extent to which establishments in any one sector are constrained by those in each other sector.

Assuming that establishments would charge high prices (and accordingly make high profits) to the extent that they are free to do so, then the highest average profits should be observed in those sectors with the highest predicted freedom from other sectors. For American manufacturing industries, this is precisely what is observed and reported elsewhere (Burt, 1979a; 1980a). Values of Equation 1 were computed for each of 20 two-digit and each of 335 four-digit Standard Industrial Classification (SIC) manufacturing industries from z_{ji} as the millions of dollars of sales from establishments in industry J to those in sector I according to

---

$a_{ji} = [\beta_s x_{ji} + \beta_x(y_j - \bar{y})(\bar{x}_{j\cdot} - x_{ji})]|a_j|$, where $\bar{x}_{j\cdot}$ is the mean constraint imposed on status S_j (cf. Burt, 1980a:Eq. 2). It is these a_{ji} that capture market constraints on profits in manufacturing industries so as to distinguish significant and negligible market constraints (Burt, 1980a:Eq. 5). However, we have focused on x_{ji} in the text since it clearly shows the connection between constraint and market structure without requiring an extensive aside on the autonomy concept or industry profits.

the 1967 Input-Output Study of the American economy where y_i was measured as the concentration of 1967 sales in the largest four establishments in each sector corresponding to SIC industries. Following the lead of economic research on industry profits, adjusted price-cost margins were computed as the relative average profits establishments obtained in 1967 within each manufacturing industry (Collins and Preston, 1969). As one indicator of the portion of a dollar of sales that was profit in an industry, this margin was close to 1 to the extent that total sales by the industry minus direct material and labor costs equalled total sales itself. As expected, those industries with high price-cost margins tended to be concentrated (high values of y_J) and be subject to low constraint from other economic sectors (low values of x_{JI} summed across all manufacturing and nonmanufacturing sectors I).

Assuming that establishments would establish cooptive relations with sectors constraining their pricing discretion within the market, then the structural autonomy model provides a structural theory of corporate cooptation: Interestablishment cooptive relations should be observed where they can eliminate constraint and should not be observed where there is no constraint to eliminate. This theory was supported in an analysis of merger rates among establishments in the two-digit SIC manufacturing industries. Based on the analysis of market constraints confronting the 20 two-digit SIC industries from establishments in 51 manufacturing and nonmanufacturing sectors in 1967, three types of market constraints among establishments can be distinguished: intra-industry, industry constraint, and industry nonconstraint.[3] These types of market relations offer three hypotheses on corporate cooptation.

(H_1) Of the 20 industries, establishments in 16 could increase their freedom from other sectors if they could establish cooptive ties with one another so as to raise y_J for the industry. In these 16 industries, establishments should be connected by cooptive relations ($w_{JJ} \neq 0$).[4] Antitrust legislation poses a bias against support for this hypothesis depending on the type of cooptive relation being considered. Cooptive ties between competitive firms within an industry are less likely than would be predicted by market constraint since such ties are rather flagrant violations of antitrust. This issue is raised again in our conclusions section.

(H_2) There were 86 intersector relations in the 1967 economy where establishments in industry J had extensive transactions with those in sector I and sector I was highly concentrated so that x_{JI} in Equation 1 was high. These 86 industry constraint relations should be associated with cooptive relations intended to eliminate constraints, establishments in industry J creating cooptive relations with those in sector I ($w_{JI} >> 0$ given $x_{JI} >> 0$).

(H_3) The remaining market relations referred to a lack of constraint on establishments in each industry. Either the establishments in sector I were not highly concentrated (meaning that there were many independent competitors within the sector) or industry J had no market transactions with the sector. For either reason, x_{JI} in Equation 1 was close to zero so that 794 industry nonconstraint relations should be associated with a lack of cooptive relations intended to eliminate constraints, establishments in industry J not creating cooptive relations with those in sector I ($w_{JI} \simeq 0$ given $x_{JI} \simeq 0$).[5]

---

[3] In order to distinguish industry constraints from nonconstraints, a 95% confidence interval is placed around 0 constraint using the standard error of the mean constraint on profits in an industry (the mean a_{JI} for industry J from all 51 economic sectors I, see fn. 2). The sector I exercised high market constraint on industry J if x_{JI} was sufficiently different from 0 to make them one of the highest constraints the industry faced in the sense that their constraint was beyond the .95 confidence interval around 0 (see Burt, 1980a:Eq. 5).

[4] Deleted are the textile, apparel, rubber and fabricated metals industries. Establishments in these industries confront such a high level of market constraint that a small decrease in competition within each industry need not decrease the overall market constraint they face. Nevertheless, there are intra-industry connections here. There are mergers in all four industries and at least two establishments in all but the apparel industry are connected by interlocking, direct as well as indirect through financial institutions.

[5] There are 794 rather than 914 (20 × 51 − 20 − 86)

These hypotheses do not describe the manner in which corporate cooptation operates. They merely locate those places in the economy where cooptive relations should and should not occur if they are intended to eliminate market constraint. In order to know what types of connections among establishments are cooptive, connections falling under hypothesis H_3 can be compared with those falling under hypotheses H_1 and H_2. A discretionary connection, tending not to occur in the absence of market constraint (H_3) but tending to occur in the presence of market constraint (H_1, H_2), is probably being used as a cooptive relation eliminating market constraint. The data on mergers as of 1967 suggest mergers to be cooptive relations in this sense. Establishments within industries had a statistically significant tendency to merge with one another and establishments in industry J tended not to merge with those in sector I if that sector exercised no market constraint on the industry. Given the commonly held assumption that interlocking directorates are cooptive relations, we expect interestablishment connections through corporate boards of directors to show the same patterning.

MEASURING INTERESTABLISHMENT CONNECTIONS THROUGH BOARDS OF DIRECTORS

Measuring the w_{JI} as interestablishment connections through boards of directors requires decisions on three issues. The issues deserve brief discussion as explanation for the decisions made here in order to operationalize the w_{JI}.

(1) Different organizational units are connected by market constraints and interlocking directorates. Market constraints are defined at the establishment level of analysis but boards of directors are defined at the corporation level of analysis. A firm is a socially defined entity created by corporate law in order to determine legal liabilities. An establishment is an economically defined entity created by the Bureau of the Census in order to describe market structure. For the purposes here, a single firm's holdings in an economic sector is one establishment. Following the Department of Commerce an industry in the economy consists of all establishments engaged in the manufacture of a single type of good. The tobacco industry consists of all establishments engaged in the manufacture of tobacco products, the food industry consists of all engaged in manufacturing food products, and so on. If a corporation owns two factories, one manufacturing bread and the other cigars, then it owns two establishments, one in the food industry and another in the tobacco industry. If a corporation owns three factories at separate locations, two engaged in the production of bread and one manufacturing cigars, then it owns two establishments, one in the food industry and another in the tobacco industry.[6] Some firms own an establishment in only one economic sector. In this circumstance market constraints among establishments and interlocking directorates among firms can be compared directly. The typical firm owns establishments in many sectors, however, so constraints and interlocking cannot be compared directly. Further, there is no obvious method of comparing constraint and interlocking by assigning firms to their most important sector or aggregating market constraints to the corporation level of analysis.[7] For this analysis, a cor-

---

nonconstraint relations because six nonmanufacturing sectors have been deleted as artificially supporting this hypothesis. The six sectors are: federal government, state/local government, gross imports, expense accounts, office supplies, and scrap. There are no SIC categories given in the 1967 Input-Output Study for these sectors, so there would have been no directorate ties to establishments in these sectors as such ties are operationalized here. Since the six sectors exercise no market constraint on any two-digit industry, considering them would have artificially raised the number of nonconstraint relations associated with a lack of interlock connections.

[6] This treatment differs slightly from that employed by the Department of Commerce. The census separates each factory within a sector as a separate establishment whether or not the factories are owned by a single corporation. Since establishment level data are not available for a national sample of firms and since the concern here is with coordination of establishments in separate sectors, two or more census establishments owned by a single firm in a single sector are treated here as a single establishment.

[7] Unfortunately, there are no reliable data available to the general public on the proportion of sales

finance establishments
primary metals establishments
transportation equipment establishments
transportation/warehousing establishments

Note: Arrows represent market constraint, solid lines represent ownership and dashed lines represent interlocking.

Figure 1. Illustrating Three Types of Directorate Ties Involving Two Firestone Tire and Rubber Establishments in 1967

porate board of directors is assumed to represent each establishment it owns no matter how small the establishment. The corporation is viewed less as the unit of cooptation than the means to cooptation. To be sure, when a representative from another firm sits on a corporate board, he represents the other firm. More important to an analysis of coopting market constraints, however, he represents the establishments owned by the other firm. It is access to those represented establishments that might allow the corporation's own establishments to coopt the market constraints they confront.

(2) Establishments are connected in multiple manners by corporate boards of directors. Three manners in which establishments can be connected through boards are illustrated in Figure 1 with selected connections involving Firestone Tire and Rubber in 1967.[8] Sectors of establishments are represented by squares and solid lines represent ownership (e.g., Firestone owned an establishment in the primary metals industry and another in the transportation equipment industry as well as several not presented in the diagram). A dashed line between two firms represents an interlocking directorate (e.g., one

---

and profits a firm obtains from its operations in each of multiple sectors. Even if such data were available, there is no obvious criterion after which a firm should be assigned to a single sector. Is a firm in industry J when one-third, one-half, or three-fourths of its income results from its operations in the industry? The task of assigning firms to specific sectors seems implausible at this time. Similarly, aggregating market constraints to the corporate level seems implausible. The typical firm operates in multiple economic sectors. Each establishment it owns is subject to the market constraints characterizing its industry. The firm itself is subject to some mixture of these market constraints collectively confronting its multiple establishments. Further complicating this mixture is the lack of data on the extent to which the firm's sales and profits result from each of its establishments. For the purposes here, it seemed preferable to oversimplify the situation by treating each of a firm's establishments as equally represented by the firm's board. This is probably not true empirically, but it has the advantage of a clear interpretation pending the development of some sophisticated method for quantitatively disaggregating firms into their component establishments.

[8] A detailed discussion of these three types of connections as cooptive relations is given elsewhere (Burt, 1980b). Also given there is a more complete picture of the establishments represented on Firestone's board of directors in 1967 by the three types of connections.

or more of Firestone's directors also sit on the board of Cleveland Trust). Finally, arrows represent market constraint relations (e.g., establishments in the primary metals industry are constrained by their market relations with those in the transportation equipment industry and those in the transportation/warehousing sector as well as some not presented in the diagram) and the absence of an arrow represents a lack of constraint (e.g., establishments in the financial sector exercise market constraint on no sector presented).

Put yourself in the position of the head executive for Firestone's establishment in the primary metals industry. Among other market constraints his establishment confronts are constraints from the transportation equipment industry and the transportation/warehousing sector. To the extent that Firestone's board of directors is a cooptive device, it should be used to give this executive access to decision making in those sectors constraining his establishment in the market. One form of access could be provided by direct ownership. The fact that Firestone owns an establishment in the transportation equipment industry means that the executive has access through Firestone's board to at least one establishment in that industry constraining him in the market. Two establishments in separate sectors can be connected by having a single firm's board own them both. A second form of access could be provided by direct interlocking. Two establishments, owned by separate firms, can be connected by a direct interlock between the two firms. In Figure 1, for example, Firestone is interlocked with Western Airlines. Since the latter owns an establishment in the transportation/warehousing sector, the executive in Firestone's primary metals establishment has a connection through Firestone's board and Western's board to at least one establishment in that sector constraining him in the market. Moreover, he has a connection indirectly via Cleveland Trust to two more establishments in that sector, one owned by American Airlines and another owned by Pan American Airlines. This illustrates a third type of interestablishment connection through the corporate board. Two establishments, owned by separate firms, can be connected by an indirect financial interlock, their respective firms both being interlocked with a bank or insurance company as a third party.[9]

In short, there is not a single type of connection between establishments through corporate boards. Multiple types of connections can occur separately. They can also occur concomitantly as multiplex connections. Ownership, direct interlocking, and indirect financial interlocking are distinguished here as very basic types of connections. However, others are possible such as indirect interlocking through a holding company or indirect ownership through a third firm owning a controlling proportion of stock in two other firms.

(3) A third problem consists of aggregating these interestablishment connections into a potentially cooptive intersector relation, w_{ji}. This problem has two parts: translating interestablishment connections into a level of potential intersector cooptation and estimating interestablishment connections involving American manufacturing industries.

There is no obvious answer to the first problem. When have the establishments in an industry coopted those in some sector as a function of the number of connections between establishments in the industry and sector? How many connections would be required for the industry to have coopted this sector? Does each establishment in the industry need to have a connection to each establishment in the sector (i.e., an industry to sector relational density of one) or is it sufficient for each to have a connection to any one establishment in the sector? Lacking guidance from theory or available research on corporate directorates, we have chosen to avoid this measurement issue by turning it around to make it more tractable. We focus on the absence of connections. We can very clearly measure the lack of a connection from each observed establishment in industry J and each observed establishment in sector I. In the absence of any connection, we know that establishments in the industry are ignoring that sector. According to the theory, this should not occur among establishments in an industry; it should not occur when the sector is a market constraint on the industry; but it should occur when the sector is not a market constraint on the industry. If there is a connection between any one establishment in the industry and any one establishment in the sector, then we shall assume the presence of some industry to sector connection without attempting to measure the level of potential cooptation it represents. This operationalization is clearly less than perfect. Potentially cooptive connections between sectors of the economy through corporate boards are reduced to binary code; w_{jl} equals present or absent. However, it corresponds to the measurement of market constraint and has the advantage of a reasonable interpretation, the absence of directorate ties clearly indicating the absence of cooptive intent if such connections are cooptive.[10]

---

[9] There have been arguments for viewing financial firms as intermediaries coordinating a group of firms (e.g., Patman, 1968; Zeitlin, 1974). This possibility is of special interest here since the finance sector exercises no market constraint on the manufacturing industries (as illustrated in Fig. 1), yet manufacturing establishments (as well as other types of establishments) are extensively interlocked with banks and insurance companies. One explanation for this contradiction to the view that interlocks are cooptive relations is the idea that finance firms are intermediaries coordinating the accounting and capital investment activities of multiple interdependent firms. Like the firms themselves, financial instituitions can be seen as the means to cooptation rather than the object of cooptation.

This still leaves the problem of estimating interestablishment connections involving American manufacturing. Beginning with the *Fortune* listing of 500 American manufacturing firms with the highest sales in 1967, the four largest firms in each of the 20 two-digit SIC manufacturing industries have been located using the SIC listings in *Poor's Directory of Corporations, Directors and Executives*. The resulting 42 firms represent large firms engaged in American manufacturing. Since a single firm can be the largest firm in multiple industries, there are 42 firms rather than 80 (four different firms in each two-digit industry). These 42 firms were not the largest manufacturing firms in the nation, although they are quite large. Liggett and Myers Tobacco is the smallest firm in the sample with its sales rank of 220 in the nation, yet it sold an impressive $384,801,000 worth of product in 1967. The sample represents American manufacturing rather than large firms, per se.[11] Members of corporate boards in all

---

[10] A more technical discussion predicts the number of connections from industry J to sector I using the level of market constraint the sector poses for the industry (Burt, 1980d). For all three types of connections through corporate boards, intraindustry connections increase exponentially with increasing levels of industry concentration and increase linearly with increases in the sector to industry constraint.

[11] Typically, firms are sampled in terms of firm size when interlocking directorates are analyzed. The pace-setting study by the National Resources Committee (Means, 1939) analyzes the 200 largest nonfinancial firms and the 50 largest financial corporations. Dooley (1969) and Allen (1974) analyze identical samples observed later (1964 and 1970 respectively). In a similar vein, Representative Patman's Subcommittee on Domestic Finance, Committee on Banking and Currency (Patman, 1968) analyzes the 500 largest industrial corporations and 200 largest nonindustrial firms in the 1966 *Fortune* listing together with 49 banks in urban centers, Mariolis (1975) analyzes the 500 largest manufacturing firms and the 247 largest nonmanufacturing firms in the 1969 *Fortune* listing, and Bearden et al. (1975) analyze the 1,131 largest firms drawn principally from the *Fortune* listings between 1963 and 1974. This sampling on a size criterion is justified using Berle and Means's (1932) finding that the top 200 nonbanking firms in 1929 controlled between 45% and 53% of the assets of all nonbanking firms. There is little need, therefore, to analyze firms beyond the largest firms if the analysis is concerned with the control of assets. Nevertheless, an innovative twist on this size criterion is given by Warner and Unwalla (1967). Defining a population of 20,989 firms listed in the 1961 *Fortune* compilation of the 750 largest American firms and the 1961 *Million Dollar Directory* from Dun and Bradstreet, a stratified random sample of 500 firms was drawn with the aid of *Moody's Industrial Manual*. The sample was stratified into eleven SIC categories and the number of sampled firms in each category approximated the proportion of total net worth of firms in the category (Warner and Unwalla, 1967:24, 124). Our concern here is less with describing interlocking among American firms than it is with testing predictions of interindustry interlocking. The sampling plan used here is similar to Warner and Unwalla's stratified random plan except that 20 two-digit SIC categories have been distinguished rather than 11 and the four largest firms in each category have been sampled rather than randomly selecting firms in each category. Since large firms are not equally distributed across manufacturing industries (large firms tending to occur in durable industries such as primary metals or fabricated metals, and in energy related industries

250 nonmanufacturing firms in the *Fortune* listing for 1967 were coded from *Poor's* and compared to the boards of the 42 manufacturing firms. Of the top 250, 110 interlocked with one or more of the 42 and have been included in the analysis. The sample of 42 firms representing manufacturing industries has been snowballed into a sample of 152 firms representative of large firms involved in American manufacturing in 1967.[12] Although small, this sample is representative of its population. An analysis of the directorates of these firms replicates past research findings discussed in our introductory remarks (see Burt, 1980b). There is extensive interlocking among the firms. Those firms most likely to be involved in interlocking are large firms controlled by diffuse interest groups. This same conclusion holds when firms or establishments are taken as the object of potentially cooptive interlocking.

Bringing the above discussion together, three binary estimates have been generated for w_{JI} as a tie from establishments in industry J to those in sector I through boards of directors:[13]

(O) There is a direct ownership tie from industry J to sector I if one or more of the 42 manufacturing firms owns an establishment in J and I (e.g., there is a tie between the primary metals and transportation equipment industries in Figure 1).[14]

(D) There is a direct interlock tie from industry J to sector I if one or more of the 42 manufacturing firms owns an establishment in industry J and interlocks with any one of the other 151 firms which in turn owns an establishment in sector I (e.g., there is a tie between the primary metals industry and finance sector in Figure 1).[15]

---

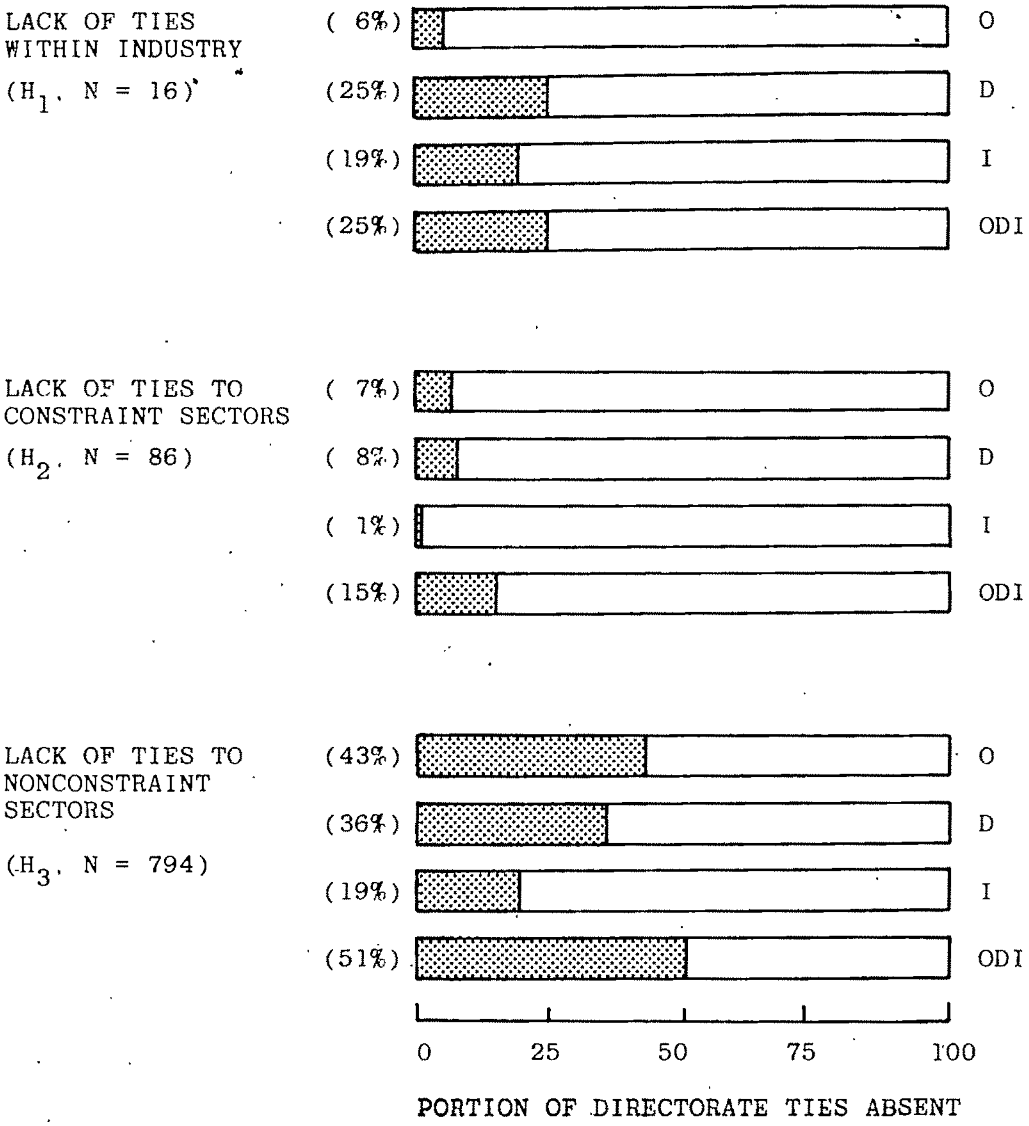
such as petroleum) an analysis of interlocking by large firms is weighted toward firms in specific industries. Given research demonstrating the different market constraints to which different industries are subject, and given interlocking as a potentially cooptive response to market constraints, firms have been sampled so as to represent all industries rather than just those with the largest firms. This sampling allows inferences to be made concerning large firms in manufacturing from an analysis of a relatively modest number of strategically selected firms.

[12] Of the 110 nonmanufacturing firms, 32 are banks, 22 are insurance firms, 21 are transportation firms, 20 are utilities (including 2 communication firms and 4 holding companies), and 15 are merchandising firms.

[13] More specifically, these directorate ties have been derived from two types of information coded for each firm from the 1968 *Poor's Directory of Corporations, Directors and Executives:* names of persons sitting on the boards of directors for each firm and the SIC categories in which each firm (including the firm's divisions and subsidiaries) owns an establishment. Numerical illustration of the manner in which these relations have been obtained is given in Burt (1979b). It may seem curious to code extensive data on all 152 firms and then only analyze the directorates of the 42 manufacturing firms. This has been done for reasons of inference. The 42 manufacturing firms represent manufacturing industries. The 110 nonmanufacturing firms have not been sampled to similarly represent nonmanufacturing sectors of the economy. Rather, they have been sampled so as to represent the extent to which the 42 manufacturing firms interlock with large corporations in nonmanufacturing sectors. Succinctly stated, the sample of 152 firms is not designed to allow a description of corporate directorates in the American economy. It is designed to make inferences about vertical integration in American manufacturing.

[14] Using the 1967 Input-Output Study's list of SIC categories corresponding to input-output sectors (*Survey of Current Business*, 54, February, pp. 34–7), a (152,45) binary matrix, D, was constructed where element (i,j) is 0 unless firm J is listed in *Poor's* as selling goods in sector I, whereupon the element was set equal to 1. There were only 45 of the 51 possible sectors considered since no SIC categories corresponded to 6 input-output sectors, so none of the firms could be listed as owning establishments in the sectors (federal government, state/local government, gross imports, expense accounts, office supplies, and scrap). D_m is then a (42,45) binary matrix consisting of the rows of D corresponding to the 42 manufacturing firms sampled. The number of manufacturing firms that own establishments in sectors I and J is then element (i,j) of the matrix: $D_m'D_m$. By definition this means that all establishments within an industry are connected since they are each owned by a corporation. In order to avoid this circularity, the intraindustry ownership relations are based on the Federal Trade Commission's *Report on Large Mergers in Manufacturing Industries and Mining*, 1948–1969. There is a direct ownership tie within industry J if there have been large mergers of establishments in the industry. These data are analyzed as corporate mergers by Burt (1980a).

[15] Using the list of directors in *Poor's*, a (152,152) binary, symmetric interlock matrix, B, was constructed in which elements b_{IJ} and b_{JI} equal 0 unless a director in firm J is also a director in firm I. The number of establishments in sector I that are accessible to manufacturing firms in industry J via direct interlocking with other firms is then given as element



Note: O refers to ownership, D refers to direct interlocking, I refers to indirect interlocking via financial firms, ODI refers to the absence of O and/or D and/or I; e.g., the 25% for ODI under hypothesis one means that establishments in four industries are not connected by ownership and/or direct interlock and/or indirect financial interlock.

Figure 2. Directorate Ties Tend Not to Occur in the Absence of Market Constraint

(I) There is an indirect financial interlock tie from industry J to sector I if one or more of the 42 manufacturing firms owns an establishment in industry J and interlocks with a bank or insurance company which in turn interlocks with any one of the other 151 firms which, in turn, owns an establishment in sector I (i.e., there is a tie between the primary metals industry and transportation/warehousing sector in Figure 1).[16]

(j,i) of the matrix: $D_m'(B_m - I_m)D$, where B_m is the (42,152) matrix consisting of the 42 rows of B corresponding to the 42 manufacturing firms sampled. I_m is a (42,152) matrix of 0's except that element (i,i) equals 1.

[16] The number of manufacturing firms in industry J that interlock via financial firms with any separate firms owning an establishment in sector I is element

RESULTS

Figure 2 presents bar graphs of the distribution of these three types of purportedly cooptive directorate ties (w_{JI}) across the known market constraints (the three hypotheses). Taking market constraint relations as an example (H_2, $x_{JI} >> 0$), there are four graphs of the proportion of the 86 constraint relations that are not countered by any interestablishment connections through corporate boards. In six cases (7%) there is an absence of ownership ties. In seven cases (8%) there is an absence of direct interlock ties. In one case (1%) there is an absence of indirect interlock ties through financial institutions. In thirteen cases (15%) one or more of the three types of directorate ties are absent simultaneously.

Overall, the data conform to the hypotheses. The absence of directorate ties is highest between establishments in an industry and those in a sector when the sector poses no market constraint on the industry (H_3). In comparison, there is a lower tendency for any one of the three types of directorate ties to be absent among establishments within an industry (H_1) and a very low tendency for any one of them to be absent between establishments in an industry and those in a sector constraining the industry (H_2).

There are some perturbations in the data, however, that make it premature to assume that the purportedly cooptive directorate ties are in fact cooptive as predicted by the theory. For one thing, there is a higher tendency for directorate ties to be absent among establishments within an industry than between establishments in the industry and those in a sector constraining the industry (H_1 versus H_2). This observation is complicated by differences in the extent to which directorate ties are absent between industries and nonconstraint sectors (H_3). Of the 794 nonconstraint relations on industry J from sector I, there are 453 instances (57%) in which establishments in J and I are connected by ownership ties versus 511 instances (64%) in which they are connected by direct interlock ties versus 647 instances (81%) in which they are connected by indirect interlock ties via financial institutions. In fact, there is an equal tendency for indirect interlock ties to be absent within an industry as well as between the industry and nonconstraint sectors (19%).

Fortunately, there is a mathematical model available for expressing the data so as to partition support for the hypotheses from differences in the extent to which each type of directorate tie is absent. For a given type of directorate tie (O, D, I or ODI), the frequency with which it is absent under hypothesis K (call this frequency f_k) can be expressed in terms of four parameters (cf. Goodman, 1970:228; 1972:1042):

$$f_k = \gamma\gamma^c\gamma_k^h\gamma_k^{ch}, \qquad (2)$$

where γ is a constant similar to the overall mean in an analysis of variance, γ^c and γ_k^h, respectively, describe the marginal tendencies for that type of tie to be absent and to fall under hypothesis K, while γ_k^{ch} describes the tendency for it to be absent under hypothesis K. A parameter is greater than 1 when it describes a condition that occurs more often than an average. If the directorate tie tends to be absent more often than it is present, for example, then γ^c will be greater than 1. If fewer relations fall under hypothesis one (H_1) than fall under all three hypotheses on the average, then γ_1^h will be less than 1. More importantly, if the directorate tie tends to be absent more often under hypothesis three (H_3) than it is across all three hypotheses, then γ_3^{ch} will be greater than 1.

The three hypotheses predict interaction terms in this model. Hypothesis one says that establishments within industries

---

(j,i) of the matrix: $D_m'(B_m^{**})D$, where B_m^{**} is a (42,152) matrix of indirect interlocking through financial institutions. Beginning with B from the previous note, all b_{IJ} are set equal to 0 if neither firm I nor firm J is a financial institution (a bank or an insurance firm). This new matrix with deleted b_{IJ}, call it B^*, is then squared (B^{*2}) so as to locate two-step chains between firms through banks and insurance firms. A (152,152) matrix, B^{**}, is obtained from the squared matrix such that b_{IJ}^{**} equals 0 unless element (i,j) of B^{*2} is greater than 0 and $J \neq I$, whereupon b_{IJ}^{**} is set equal to 1 since it represents an indirect connection between firms I and J via one or more financial firms. The submatrix B_m^{**} is then the (42,152) matrix consisting of the 42 rows of B^{**} corresponding to the 42 firms in the manufacturing sample.

Table 1. Predicting the Absence of Directorate Ties

	Cooptive Relations			
Parameters	0	D	I	ODI
γ	32.19	39.57	26.09	43.92
γ^c	.39	.50	.29	.63
γ_1^h	.12	.18	.24	.16
γ_2^h	.68	.59	.35	.70
γ_3^h	12.21	9:61	11.82	9.04
Interaction Terms (unit normal tests of significance in parentheses)				
γ_1^{ch}	.65	1.15	1.65	.92

γ_3^{ch}	2.20	1.48	1.63	1.63
	(4.2)***	(3.3)***	(2.4)**	(4.4)***
$\chi^2(\gamma_1^{ch} = \gamma_2^{ch} = \gamma_3^{ch} = 1)$	61.23***	33.21***	25.60***	47.97***

* $p < .05$.
** $p < .01$.
*** $p < .001$.

will be connected by cooptive relations. If directorate ties are the cooptive relations they are purported to be, than γ_1^{ch} should be less than 1; there should be few industries in which directorate ties are absent. Hypothesis two (H_2) says that establishments in an industry will create cooptive relations with establishments in sectors constraining the industry. If directorate ties are cooptive, therefore, γ_2^{ch} also should be less than 1; there should be few industries from which directorate ties to constraint sectors are absent. In contrast, hypothesis three says that establishments in an industry will ignore nonconstraint sectors so γ_3^{ch} should be greater than 1 if directorate ties are cooptive; there should be many industries from which directorate ties to nonconstraint sectors are absent.

Using the data in Figure 2, Table 1 presents estimates of the gamma parameters for the different directorate ties.[17] Note that the frequency with which any type of tie is absent under any hypothesis can be perfectly reconstructed from the parameters in Table 1. The one case in which an industry is not connected by indirect interlocking (I) to a sector constraining profits in the industry, for example, consists of a mean effect ($\hat{\gamma} = 26.09$) multiplied by a tendency for indirect interlocking to be absent ($\hat{\gamma}^c = .29$) multiplied by a tendency for relations to fall under hypothesis two ($\hat{\gamma}_2^h = .35$) multiplied by a tendency for indirect interlocking to be absent under hypothesis two ($\hat{\gamma}_2^{ch} = .37$): $1 = 26.09(.29)(.35)(.37)$. In keeping with the obvious features of Figure 2, directorate ties consistently tend to be absent less often than they are present (all $\hat{\gamma}^c$ are less than 1) and relations more often fall under hypothesis three than the other hypotheses (all $\hat{\gamma}_3^h$ are much greater than 1 while all $\hat{\gamma}_1^h$ and $\hat{\gamma}_2^h$ are less than 1).

Also presented in Table 1 are statistical tests of the interaction parameters predicted under the three hypotheses.[18]

---

[17] Frequencies for each type of directorate tie can be computed directly from Figure 2. Let n_k refer to the number of relations falling under each hypothesis ($n_1 = 16$, $n_2 = 86$ and $n_3 = 794$). The f_k can then be computed from the percentages in Figure 2. For example, 6% of n_1 do not have ownership tie(s), so f_k for ownership is .06(16), or 1. The number of intra-industry relations for which ownership tie(s) are present is then $n_k - f_k$, or 15. As described by Goodman (1972:1046), the effects are computed as geometric means:

$$\gamma = (\Pi_k^3(n_k - f_k)f_k)^{1/6},\ \gamma^c = ((\Pi_k^3 f_k)^{1/3})/\gamma,$$
$$\gamma_k^{ch} = f_k/(\gamma^c \gamma_k^h \gamma),\ \gamma_k^h = ((f_k(n_k - f_k))^{1/2})/\gamma.$$

[18] Statistical interpretations of the gamma coefficients assume that each of the 896 w_{ij} is independently observed. As with much of network analysis, it is difficult here to determine the correct number of independent observations underlying second-order coefficients. The cooptive relations have been computed from 152 separate firms for which 2,903 different persons serve as directors and the firms together owned 414 of what we are treating here as establishments (a conservative estimate of what the Department of Commerce treats as establishments in con-

Completely eliminating interaction between market constraint and directorate ties (i.e., imposing the restriction that $1 = \gamma_1^{ch} = \gamma_2^{ch} = \gamma_3^{ch}$) reduces the ability of the model to recreate the observed data at well beyond the .001 level of confidence for each type of directorate tie. There is a strong interaction between market constraint and directorate ties. Looking at the individual parameters themselves, it is clear that this significant overall interaction is not a result of support for hypothesis one. Ownership ties (O) and multiplex directorate ties (ODI) have the predicted low tendency to be absent among establishments within industries; however, neither tendency is statistically significant.[19] Furthermore, the direct and indirect interlock ties (D and I) tend to be absent within industries, the indirect interlock ties significantly so ($\hat{\gamma}_1^{ch} = 1.65$, with a unit normal test of 1.8 indicating that the estimate is significantly greater than 1 at beyond the .05 level of confidence). The overall interaction between market constraint and directorate ties is a result of strong support for hypotheses two and three. As predicted by hypothesis two, each type of directorate tie has a low tendency to be absent between establishments in an industry and those in a sector when the sector constrains the industry (for O, D and I, $\hat{\gamma}_2^{ch}$ is significantly less than 1). As predicted by hypothesis three, each type of directorate tie tends to be absent when the sector does not constrain the industry ($\hat{\gamma}_3^{ch}$ is significantly greater than 1 for O, D and I). Beyond these tendencies for each type of directorate tie to be patterned by market constraints, Table 1 shows that the three occur together according to market constraints. If a sector constrains an industry, then all three types of directorate ties tend to exist between establishments in the industry and those in the sector ($\hat{\gamma}_2^{ch}$ for ODI is less than 1 at beyond the .01 level of confidence). In the absence of such constraint, one or more of the types of directorate ties tend to be absent ($\hat{\gamma}_3^{ch}$ for ODI is greater than 1 at well beyond the .001 level of confidence).

It is not surprising to find directorate ties coordinated as ODI multiplex ties if ties are intended to coopt sources of market constraint, multiplex relations typically being stronger than uniplex relations. But there is value in knowing the specific manner in which the three types of ties are coordinated since they constitute different levels of interorganizational control and so define different cooptive strategies when used in different combinations (see Burt, 1980b:Fig. 2, for detailed discussion). Of the relations that are not ODI multiplex in Figure 1, how many are null ties, how many represent individual ties (O, or D, or I), and how many represent coordinated pairs of directorate ties (OD, or OI, or DI)?

Table 2 presents the distribution of each observed combination of ties across the three hypotheses. Let f_{mk} be the frequency with which the m^th^ combination of directorate ties occurs under hypothesis K. For example: there are 142 cases in which establishments in an industry have no directorate ties to establishments in nonconstraint sectors ($f_{13} = 142$); there are 2 cases in which establishments within an industry are connected only by ownership ties ($f_{21} = 2$); there are 12 cases in which establishments within an industry are connected by all three types of directorate ties ($f_{81} = 12$); and so on. Just as the data in Figure 2 are expressed in terms of pa-

---

structing the input-output table, see fn. 5). Any one, or some mixture, of these numbers could be the correct number of independent observations. Further complicating the situation, the independence of observations is not equal across the three hypotheses since there is a more likely interdependence between w_{ii} and w_{jk} than between w_{jj} and w_{kk}, separate firms being more likely across two separate industries than within an industry. In the absence of a more appropriate treatment, we have merely assumed the w_{ii} to be independent and reported standard statistical interpretations of the gammas and their significance.

[19] Estimation of the gamma parameters can be improved (in terms of increased efficiency and decreased asymptotic bias) here by adjusting the observed f_k by a constant; Goodman (1970:229) suggests an increase of 1/2. So altering the observed f_k does not affect the conclusions based on Table 1. Slight modifications in the gammas and their error variances occur, but the modifications are minimal. The most serious change is an increase in the unit normal test of $\hat{\gamma}_2^{ch}$ for indirect interlocking (I) and multiplex directorate ties (ODI) from their current values of 2.8 and 2.9 to a value of 3.0. This would make both coefficients less than 1 at beyond the .001 level of confidence rather than the .01 level presented in Table 1.

Table 2. Multiplex Directorate Ties and Market Constraints

Combinations of Directorate Ties*	Market Constraint H_1	H_2	h_3	Total
null	1	1	142	144
O	2	0	2	4
D	0	0	3	3
I	0	0	70	70
OD	0	0	0	0
OI	1	7	68	76
DI	0	5	121	126
ODI	12	73	388	473
Total	16	86	794	896

* Null refers to the complete absence of any ties between establishments, O refers to one or more ownership ties, D refers to one or more direct interlock ties, and I refers to one or more indirect interlock ties via financial institutions. OD, OI, DI and ODI refer to the simultaneous presence of combinations of the three types of directorate ties.

rameters in Table 1, the data in Table 2 can be expressed in terms of the following parameters:[20]

$$f_{mk} \cong \gamma\gamma^{c}_{m}\gamma^{h}_{k}\gamma^{ch}_{mk}, \qquad (3)$$

where γ and γ^{h}_{k} respectively describe the overall mean and the tendency for relations to occur under hypothesis K. The tendency for the mth combination of directorate ties to occur is described by γ^{c}_{m} and its tendency to occur under hypothesis K is described by the interaction term γ^{ch}_{mk}. Table 3 presents estimates of the γ^{c}_{m} and γ^{ch}_{mk} for Table 2.[21] Recalling the discussion of Table 1, a coefficient greater than 1 indicates a condition that occurs more often than would be expected on the average.

Column one of Table 3 shows that the three types of directorate ties tend to occur together as multiplex directorate

---

[20] It might appear to be more straightforward to estimate the saturated model for the four-way table (hypothesis, O, D, I) directly here; however, such a model does not capture directorate tie multiplexity. The problem is that interactions in the model do not capture multiplexity. This is not obvious, so a quick justification is in order. Consider a three-way table cross-tabulating Ownership (no, yes), Direct interlock (no, yes), and Hypothesis (nonconstraint – H_3, constraint – H_1 and H_2). Ownership and direct interlock ties should occur as multiplex directorate ties in the presence of market constraint. The frequency with which the ith level of ownership and jth level of direct interlock occur under the kth level of hypothesis, f^{HOD}_{kij}, is given in terms of eight parameters:

$$f^{HOD}_{kij} = \gamma\gamma^{H}_{k}\gamma^{O}_{i}\gamma^{D}_{j}\gamma^{OD}_{ij}[\gamma^{HO}_{ki}\gamma^{HD}_{kj}\gamma^{HOD}_{kij}],$$

where the parameters in brackets capture the interaction of the two types of directorate ties with constraint. Note three points in this specification: (1) There is no parameter capturing the association between null ties (the simultaneous absence of O and D) and market constraint since this condition is absorbed into the other parameters. This means that there is no independent test for the hypothesis that directorate ties tend to be simultaneously absent in the absence of market constraint. (2) The parameter capturing an interaction between ownership and direct interlock, γ^{OD}, is not the tendency for OD multiplexity to occur—it is the tendency for ownership ties and direct interlock ties to occur together and/or to be simultaneously absent:

$$\gamma^{OD}_{11} = \gamma^{OD}_{22} = [\Pi^{2}_{k}(f_{k11}f_{k22}/f_{k21}f_{k12})]^{1/8},$$

which is the fourth power of the mean odds-ratio between O and D (e.g., Goodman, 1972:1042). In other words, if ownership ties and direct interlock ties tend to be simultaneously absent but only have a random tendency to occur together, this interaction parameter will be high. This is not what is meant by relational multiplexity (see Burt, 1980c:89–90, for review and references). A hermit has no relations with others and so at once has no social relation or economic relation to any particular other, but this does not mean that the hermit has coordinated his relations as multiplex ties to others. Rather, it means that he is an isolate. Multiplexity refers to the simultaneous presence of different types of relations from one actor to another. The simultaneous absence of relations is a wholly different concept. (3) The impropriety of γ^{OD} as a measure of multiplexity carries over to γ^{HOD} as the parameter capturing the interaction between constraint, ownership, and direct interlock. This third order interaction is the tendency for O and D to be simultaneously present or absent in the presence versus the absence of market constraint:

$$\gamma^{HOD}_{122} = \gamma^{HOD}_{111} = [(f_{111}f_{122}/f_{121}f_{112})/(f_{211}f_{222}/f_{221}f_{212})]^{1/8},$$

which is proportional to the odds-ratio between O and D in the absence of market constraint over the odds-ratio in the presence of constraint. Again, it can be high either because O and D tend to occur together in the absence of constraint or because they tend to be simultaneously absent in the absence of constraint.

[21] Since there are several empty cells in Table 2, parameters have been estimated from frequencies increased by 1/2. Deleting the nonexistent OD category, effects are computed in a manner only slightly more complicated than that used for Table 1. The overall mean effect is the geometric mean of frequencies in all 21 cells; $\hat{\gamma} = 5.27$. The tendency for relations to occur under hypothesis K is the geometric mean of frequencies under the hypothesis given the overall mean:

$$\gamma^{h}_{k} = [(\Pi^{7}_{m}f_{mk})^{1/7}]/\gamma,$$

so that $\hat{\gamma}^{h}_{1} = .26$, $\hat{\gamma}^{h}_{2} = .47$, and $\hat{\gamma}^{h}_{3} = 8.22$. The tendency for the mth combination of directorate ties to occur and its interaction with hypothesis K are then given as the following ratios of geometric means: $\gamma^{c}_{m} = [(\Pi^{3}_{k}f_{mk})^{1/3}]/\gamma$ and $\gamma^{ch}_{mk} = f_{mk}/(\gamma^{c}_{m}\gamma^{h}_{k}\gamma)$.

Table 3. Predicting the Multiplex Directorate Ties in Table 2

Combinations of Directorate Ties	Parameters			
	γ^{c}_{m}	γ^{ch}_{m1}	γ^{ch}_{m2}	γ^{ch}_{m3}
null	1.30	.85	.47	2.53
	(.7)	(.3)	(1.3)	(2.4)**
O	.28	6.60	.73	.21
	(2.5)**	(3.0)***	(.4)	(2.6)**
D	.18	2.02	1.11	.45
	(2.8)**	(.7)	(.1)	(1.2)

OI	1.74	.63	1.74	.91
	(1.8)*	(.8)	(1.3)	(.3)
DI	1.32	.28	1.69	2.13
	(.6)	(1.5)	(1.0)	(1.6)*
ODI	13.47	.68	2.21	.67
	(12.6)***	(1.1)	(2.6)**	(1.8)*

* $p < .05$.
** $p < .01$.
*** $p < .001$.

ties. Ownership ties (O), direct interlock ties (D), and indirect interlock ties via financial firms (I) tend not to occur independently ($\hat{\gamma}^{c}_{2}$, $\hat{\gamma}^{c}_{3}$ and $\hat{\gamma}^{c}_{4}$ are all less than 1). For ownership and direct interlock ties, this tendency is significant beyond the .01 level of confidence. Ties have various tendencies to occur together in pairs. While ownership and direct interlock ties (OD) never occur together, direct interlock ties occur with indirect interlock ties (DI) and ownership ties occur with indirect interlock ties (OI) more often than would be expected on average. However, only the OI multiplexity has a statistically significant tendency to occur ($p < .05$). Rather than occurring in pairs, the three types of cooptive ties tend to occur simultaneously. Far and away the strongest effect in Table 3 is the tendency for ODI multiplex directorate ties to occur (the unit normal test statistic of 12.6 is significant at well beyond the .001 level of confidence).

There is a significant overall interaction between market constraint and the different types of directorate ties. Imposing the restriction that all interaction parameters (the γ^{ch}_{mk}) be equal to 1 noticeably reduces our ability to predict the observed frequencies in Table 2. The likelihood-ratio chi-square of 70.73 with 12 degrees of freedom is significant at well beyond the .001 level of confidence.

Assessing each hypothesis individually, the second column of Table 3 offers meager support for hypothesis one. There is a significant tendency for establishments within an industry to be connected by uniplex ownership ties ($\hat{\gamma}^{ch}_{22}$ is 6.60 with a unit normal test indicating a significance at the .001 level of confidence). There are no other significant interaction effects for hypothesis one. Although establishments in 12 of the 16 industries are connected by all three types of directorate ties simultaneously (ODI multiplexity), this is not a statistically significant frequency since ODI multiplexity has such a high tendency to occur on the average across all three hypotheses.

In support of hypothesis two, all three types of directorate ties tend to occur simultaneously between establishments in an industry and those in a sector constraining the industry. Although having a high tendency to occur across all three hypotheses ($\hat{\gamma}^{c}_{8} = 13.47$), ODI multiplexity occurs under hypothesis two with an increased frequency significant at beyond the .01 level of confidence ($\hat{\gamma}^{ch}_{82}$ is 2.21 with a unit normal test of 2.6). There are no other significant interaction effects under hypothesis two; however, as a complement to the ODI multiplexity, it is unusual to find establishments in an industry unconnected by any of the three directorate ties to establishments in a sector constraining the industry ($\hat{\gamma}^{ch}_{12}$ is .47, but this is not significantly less than 1, even at the .05 level of confidence).

In support of hypothesis three, establishments in an industry tend to have none of the three directorate ties with establishments in a sector not constraining the industry. The tendency for null directorate ties (the simultaneous absence of ownership ties and direct interlock ties as well as indirect interlock ties via financial institutions) to occur in this absence of market constraint is significant at the .01 level of confidence ($\hat{\gamma}^{ch}_{13} = 2.54$). Also as would be expected under hypothesis three, there is a significant tendency for all three directorate ties not to be present simultaneously in the absence of market constraint. The interaction effect for ODI multiplexity and the absence of market constraint is less than 1 at beyond the .05 level of confidence ($\hat{\gamma}^{ch}_{83}$ is .67 with a unit normal test of 1.8).[22]

CONCLUSIONS

In conclusion, the network model of structural autonomy seems to be accurate in predicting where directorate ties occur in the American economy as cooptive relations, relations intended to eliminate market constraints. Each of the directorate ties considered (establishments connected through corporate boards by ownership, direct interlocking, and indirect financial interlocking) tends to occur where there is market constraint and tends to be absent in the absence of constraint. Moreover, the directorate ties occur simultaneously as multiplex directorate ties. If one or more of the establishments in an industry are connected by any one of the three types of directorate ties to establishments in some other economic sector, then it is likely that establishment(s) in the industry and sector are also connected by the other two types of directorate ties. This is particularly likely when the industry is constrained by its market transactions with establishments in the sector. In the absence of such market constraint, all three types of directorate ties tend to be simultaneously absent between establishments in the industry and sector.

These results suggest that the study of intraindustry cooptation through directorate ties should be treated as a special case apart from interindustry cooptation. Despite the strong support for intraindustry cooptation using merger data (Burt, 1980a), support using directorate ties is weak. There is a marked tendency for establishments within an industry not to be connected by interlock ties, direct or indirect. One plausible reason for this is federal regulation of the market. When establishments within an industry merge, or in some other manner create an ownership tie between them by coming under the jurisdiction of a single directorate, then they no longer exist as independent competitors within the industry. The creation of an interlock tie, in contrast, involves a connection between separate competitive firms operating in the industry, a connection easily visible to persons outside both firms and clearly a violation of antitrust legislation intended to prevent collusion between competitors (cf. Dooley, 1969:319). In short, cooptive relations that eliminate the corporate sovereignty of competing establishments within an industry are more likely to conform to hypotheses regarding intraindustry market constraint than are cooptive relations (such as interlock ties) which create institutionalized communication channels between separate corporations.

---

[22] Contrary to hypothesis three, however, there is a significant tendency for indirect interlock ties via financial institutions to occur in the absence of market constraint. Both uniplex indirect interlock ties (I) and multiplex direct/indirect interlock ties (DI) occur under hypothesis three with a frequency significant at the .05 level of confidence. Unfortunately, there is no method of estimating the extent to which these deviations from hypothesis three can be attributed to the lack of control firms have over selecting each establishment they reach by this type of directorate tie. Since interestablishment connections are measured here by treating each of a firm's establishments equally, one manufacturing establishment can be connected to a vast number of establishments through a single indirect interlock. For example, the two establishments American Airlines owned in the retail/wholesale and personal services sectors in 1967 are deleted from Figure 1. Neither of these sectors poses a market constraint for any of the industries in which Firestone owned an establishment. However, the indirect interlock that connected Firestone to American's establishment in the transportation/warehousing sector (a source of constraint on Firestone's establishments) brought with it unnecessary connections to the retail/wholesale and personal services sectors. Without better data on the links between establishments and their parent firms, direct and indirect interlock ties are likely to overstate interestablishment cooptive relations so that hypothesis three will be rejected spuriously. We have therefore focused on multiplex directorate ties in the text.

Returning to cooptation more generally, our results on directorate ties make even more apparent the need for an understanding of how, as opposed to why, cooptation can operate through directorate ties. We have focused on binary code, the absence versus presence, of directorate ties since we have no method of measuring the intensity of cooptation represented by an absolute number of such ties. How does the number and nature of directorate ties between establishments in two sectors translate into cooptation? There is no easy answer here since the importance of a potentially cooptive directorate tie is contingent on the individual constituting the tie. When an owner or senior officer in one firm sits on the board of another firm, the two firms could be considered to be more closely tied than would be the case if a consulting lawyer for both firms sat on their respective boards. The distribution of persons a firm uses to interface with its corporate environment has been studied. Indeed, "boundary" personnel are an important feature of Evan's (1965; 1972) discussion of the organization-set connecting a firm with its corporate environment (e.g., Hirsch, 1972, provides an application to some firms in the communication, broadcasting and amusement sectors). Questions on the roles of directors and officers as connections between establishments remain. For example, how are types of persons used to connect types of sectors?[23] Are directors randomly assigned to interlock with manufacturing firms versus financial firms versus other types of nonmanufacturing firms? If not, how does the systematic assignment of types of persons to types of directorate ties vary by the intensity of market constraint they are intended to coopt? If establishments in an industry are highly constrained by their market transactions with establishments in a specific sector, one might expect them to use their senior officers to represent them on the corporate boards of firms owning establishments in the problematic sector. This raises the issue of asymmetry in directorate ties. We have considered directorate ties only in their traditionally symmetric form. If firm J is interlocked with firm I, then firm I is interlocked with firm J. However, market constraint can be asymmetric. Establishments in industry J can be constrained by those in industry I without also constituting one of the market constraints faced by industry I (x_{JI} need not equal x_{IJ} in Equation 1). It is quite possible that our findings are the result of exploitation rather than cooptation. Given the multiplex directorate tie w_{JI} superimposed on a market constraint x_{JI}, have establishments in industry J attempted to coopt the constraint they face from sector I or have establishments in sector I exploited their market constraint on industry J? An answer to this question requires more detailed information on how the people providing the directorate tie function within the respective establishments.

Perhaps more important than an understanding of how cooptation might operate through directorate ties (although difficult to address without such an understanding) is a knowledge of the consequences of cooptively successful directorate ties. Systematic empirical research on corporate cooptation (that is to say, research generalizing beyond case studies of cooptive efforts by more than a handful of firms) has consisted of describing the extent to which potentially cooptive directorate ties occur among large firms. We reviewed examples in our introductory comments. Such description falls somewhat short of providing a theoretical understanding of the etiology or consequences of corporate cooptation.[24] Moving beyond a description of the distribution of directorate ties in the American economy, we have shown that such ties are patterned by market constraints and so appear to be cooptive relations. This is only half the battle. The immediate question raised by our results is whether or not such patterning is capable of eliminating market constraints. Merely having a multiplex directorate tie superimposed on a market constraint is not equivalent to eliminating the constraint. In fact, if every market constraint has superimposed on it a multiplex directorate tie coopting it, a whole new class of unanticipated constraints in a social market arises. In order to give establishments in one or more industries an unfair market advantage, directorate ties must be used with unequal effectiveness in coopting market constraints across industries. In the same manner that the existence of an oligopoly within an industry allows high profits in the industry, effective elimination of the market constraints faced by the industry allows high profits in the industry. But in a preliminary analysis of the effectiveness of merger ties, Burt (1980a) found establishments in each two-digit SIC industry to be connected to almost every sector constraining the industry. Our results extend these findings to the more general case of ODI multiplex directorate ties. In other words, strategic cooptation of market constraints could be a necessary precursor to corporate survival rather than an opportunity for increasing profits. If this is the case, then the original impetus for researching cooptive uses of directorates as a menace to the free market is lost. Rather, the widespread use of directorate ties to coopt market constraints could have created a dual market, an economic market consisting of sales and purchase transactions and a social market consisting of formal and informal interorganizational cooptive relations. We know directorate ties are patterned by market constraints. Needed here is research on the profits obtained by such patterning.

---

[23] Allen (1977) presents some results relevant to this question by describing some attributes of persons holding four or more positions as director in 250 large firms in 1935 versus 1970. These elite directors tended to be affiliated with financial institutions or manufacturing firms, tended not to come from the upper class (about 20% were upper class), and evidenced careers as managers rather than entrepreneurs or inheritors. Systematically comparing directors sitting on four or more directorates with those sitting on fewer, Useem (1979) shows that those directors holding multiple positions in 1969 were more likely to be involved than single position directors in the governance of nonprofit private organizations, in advising governmental agencies, and in participating in business policy associations. Still, the process by which directors might influence establishments and the "career" of being a successful director are only vaguely documented.

[24] This shortcoming is not invisible to the general public. In a recent compilation of top stockholders in each of 122 large American corporations (Metcalf, 1978), New York's Morgan Guaranty Trust was the number one stockholder in 27 corporations. A staff writer for *Time* (Vol. 111, no. 5, p. 50) seemed to agree with the bank's response: "Morgan Guaranty was quick to respond. Said a spokesman: 'Where are the examples of abuse?' Indeed, the study seemed to shed a lot more light on the extent of stock-power concentration than on its effects, good or ill."

We seem to be raising more questions than our results have answered, but anyone who has spent time reading through directorate memberships or spent time talking with directors themselves, knows that there is no single explanation for each director sitting where he does.[25] Some persons are directors because of connections to a firm's owners or because they participate in the day-to-day management of the firm. Others are directors because they are influential with other firms or because they have influence in a firm's community. Still others are directors because of the expertise they bring to the firm. The many reasons for holding a position as director make it difficult for social scientists to interpret, with any generality, potentially cooptive uses of the directorate. Each use seems to have its own ideographic explanation. Such difficulty notwithstanding, it seems clear, judging from the evidence that we have seen, that there is a pattern to directorate ties, a pattern predictable from the network of market constraints in which directorates operate.

MANUSCRIPTS FOR THE
ASA ROSE SOCIOLOGY SERIES

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Suzanne Keller, Department of Sociology, Princeton University, Princeton, NJ 08540.

THE EFFECT OF SEXUAL STRATIFICATION BY RACE ON OFFICIAL REACTIONS TO RAPE*

GARY D. LAFREE
University of New Mexico

American Sociological Review 1980, Vol. 45 (October):842–854

Collins argues that sexual access, like other valuable commodities, is distributed according to relative power within a sexual stratification system. He predicts more serious official reactions to violations of the sexual stratification system in which men from less powerful groups sexually assault women from more powerful groups. Race continues to be an obvious correlate of stratified sexual access in America. But empirical studies have not assessed the cumulative effect of racial composition of victim-suspect dyads on processing outcomes in sexual assault cases. The present study examined the effect of race composition on processing decisions—from case report to final disposition—for 881 sexual assaults in a large, midwestern city. Step-wise multiple regression analysis showed that, compared to other defendants, black men who assaulted white women received (1) more serious charges and (2) longer sentences, and were more likely to (3) have their cases filed as felonies, (4) receive executed sentences, and (5) be incarcerated in the state penitentiary. At the same time, black men who assaulted white women were no more likely than other suspects to be arrested or found guilty. The implications of the results for a sexual stratification theory of official reactions to sexual assault are discussed.

A central question in criminology since Sellin (1928) has been the extent to which the defendant's race affects processing decisions in criminal cases. Given the long history of black-white sexual segregation in the United States (Rowan, 1952; Woodward, 1955), sociologists have been especially concerned with assessing differential processing in sexual assault cases (e.g., Johnson, 1957; Partington, 1965; Wolfgang and Riedel, 1973). Recent research in victimology (e.g., Sebba and Cahan, 1975; Nelson and Amir, 1975) and the recognition of rape as a serious social problem (Battelle, 1975; Rose, 1977) have focused research attention on the effect of the victim's race and the racial composition of the victim-defendant dyad on official reactions to rape.

Contemporary conflict theorists (e.g., Turk, 1969; Quinney, 1970; Chambliss and Seidman, 1971; Collins, 1975) provide an explanation for racial discrimination in the application of the criminal law. They argue that political power, in close association with social class position, is the basic determinant of organizational rewards and constraints. Access to scarce resources is determined, in part, by membership in societal subgroups, defined especially by class and race. Conflict theorists argue that the criminal law is a tool created and enforced by powerful subgroups to maintain their own favorable access to organizational rewards and to limit access of less powerful subgroups to these rewards. Thus, Chambliss (1969:856) and Chambliss and Seidman (1971) argue that the "administration of the criminal law is a highly selective process that involves the use of a wide range of discretion" that results in "systematic bias in law enforcement."

Since Marx (in Mills, 1948), conflict theorists have emphasized differential access to economic rewards. But the conflict argument can be applied to other resources that are both valued and scarce. Davis (1949) and Collins (1975:228–34) argue that sexual access is such a resource. Like other scarce resources, sexual access is determined by power relationships within a highly stratified sexual market. The basic characteristic of this stratification system is the institution of sexual property, "the relatively permanent

Part of this research was completed while the author was supported by grant number R01 MH29727-01A1 National Center for the Prevention and Control of Rape, National Institute of Mental Health. I wish to thank Phil May, Art St. George, several anonymous reviewers, and, especially, Barbara Reskin for their helpful comments on earlier drafts of this paper.

claim to exclusive sexual rights over a particular person" (Collins, 1975:234). "Sexual-property" rules are the basic structure of kinship systems (Levi-Strauss, 1949); they determine who can mate with whom and under what circumstances. Definition of the concept is parallel to that of "economic property": property is not lands or buildings themselves but, rather, the social relationships that guarantee access to them (see Collins, 1975:234). Rules of sexual access, like class relationships, are not immutable. They are subject to constant challenge and must be maintained through bargaining, threats, alliances, and force. Collins (1975:282) expresses the relationship between power and reactions to sexual-property violations as a general proposition:

> The greater the power of dominant individuals to appropriate others as sexual property, the stronger the taboo and the greater the outrage at violations of these property rights.

In its extreme form during the period of American slavery, the sexual stratification system placed few constraints on sexual access to black women by white men. By contrast, sexual access to white women by black men was carefully constrained and sanctions for the violation of these constraints were harsh (Myrdal, 1944; Woodward, 1955; Wolfgang and Cohen, 1970).

To the extent that relationships between men and women in America are still defined by race-specific rules of sexual access, an implicit ordering of official reactions to sexual assault by race of the victim and offender is suggested. Assuming that blacks are the less powerful subgroup, (1) the assault of white women by black men should result in the most serious sanctions, followed by (2) the assault of white women by white men, (3) black women by black men and, finally, (4) black women by white men. The research that follows empirically examines this proposition for a set of forcible-rape cases.

PRIOR RESEARCH

A review of prior research indicates major disagreement about the effect of race on official reactions to rape. Research completed before 1970 (e.g., Lemert and Roseberg, 1948; Johnson, 1957; Bullock, 1961; Partington, 1965) generally concluded that black defendants received more-serious official sanctions than white defendants.[1] But in a comprehensive review, Hagan (1974) notes important problems with this research. Several studies (e.g., Johnson, 1957; Bullock, 1961) *rely* on tests of significance to interpret statistical results. Hagan, however, claims that significance tests should be interpreted cautiously because they do not indicate the *strength* of relationships and are dependent on sample size (a relevant criticism because many sentencing studies include large samples). Other studies (e.g., Bullock, 1961; Partington, 1965) do not control for theoretically important variables, such as defendant's criminal record. Hagan also notes that, with few exceptions (Judson et al., 1969), the effect of defendant's race on sentencing is examined only for southern states.

By contrast, recent research (e.g., Chiricos and Waldo, 1975; Bernstein et al., 1977; Hindelang, 1978) reports little racial discrimination against defendants in criminal processing. Hindelang compares black-white arrest rates from Uniform Crime Report Statistics to results from the National Crime Panel victimization survey. Finding virtually no difference between official- and self-report rates, he concludes that high black crime rates represent actual behavior and not selection bias. Similarly, Bernstein et al. (1977) examine data for a sample of male defendants charged with felonies in New York. They analyze three official processing decisions: (1) the decision to fully prosecute, (2) the decision to withhold formal conviction and sentencing, and (3) the severity of sentences. The researchers find no support for the argument that official reactions are harsher for black than for white defendants. They (p. 754) conclude that "the theoretical focus of [labelling theory] requires considerable shifting." Finally, to test the conflict proposition that the most-severe official sanctions are reserved for lower-class persons, Chiricos and Waldo (1975) examine prison sentences received by inmates from three southeastern states. Their results indicate that defendants' race has no effect on sentence severity. They (p. 769) claim that "the evidence . . . consistently fails to support the expectations of conflict criminologists with regard to the state's sanctioning machinery."

---

[1] For a representative sample of the research on racial discrimination in the criminal justice system, see Atkinson and Neuman (1970); Baab and Furgeson (1968); Burke and Turk (1975); Hagan (1974); and Gibson (1978).

Recent research, then, provides little support for the argument that official reactions to crime are affected by the defendant's race. This research is important because it avoids many of the methodological problems of prior studies. However, recent studies on racial discrimination in criminal processing are limited in two respects that are relevant here. First, with few exceptions (Wolfgang and Riedel, 1973), recent research ignores the racial *composition* of the victim-defendant dyad. Collins's (1975) theory of sexual stratification suggests that racial composition—and not individual attributes—of either defendant or victim is most important for predicting official reactions to sexual violation. Second, recent studies of criminal processing examine only one or two processing outcomes (e.g., arrest, sentencing). But, assuming that discriminatory treatment is cumulative, an examination of only one decision may not accurately reflect the effect of processing as a whole. Observing the same problem, Hagan (1974:379) notes: "What is required is longitudinal data, based on observations of defendants' experiences in transit through the criminal justice system" (see also Bernstein et al., 1977:754).

No research, to date, has systematically analyzed the effect of the racial composition of the victim-defendant dyad on processing decisions for the entire criminal selection process. In this study, I present longitudinal data on the determinants of official processing decisions in sexual-assault cases from initial police report to final disposition. My specific purpose is to assess empirically the proposition that the seriousness of reactions to reported sexual assaults will depend on the racial composition of the victim-defendant dyad.

DATA

Sample

The sample for this study consists of 881 suspects charged with "forcible sex offenses"[2] in a large, midwestern city, between January, 1970, and December, 1975.[3] Police, prosecution, and court records provided data on defendants' and victims' demographic characteristics. For each case, I recorded evidence from prosecution files, the defendant's criminal history from police records, and final disposition and sentence from court records. Qualitative data, in the form of observations and interviews with processing agents, supplement the case-specific data and are used to interpret statistical results. I completed observations and interviews over a 12-month period while employed as a research associate by the Prosecutor's Office.

The Criminal Selection Process

Figure 1 presents the major processing decisions made in sexual-assault cases reported to police in the years examined. Two features of Figure 1 are worth noting. First, less than 10% of the 881 defendants received sentences that included incarceration. This means that research examining only sentencing outcomes (e.g., Bullock, 1961; Chiricos and Waldo, 1975) draws conclusions on the basis of a highly select group of cases. Second, while arrest is a consequential processing decision, less than 32% of the suspects arrested were eventually convicted. Thus, studies which

---

[2] "Forcible sex offenses" include rape, armed rape, sodomy, armed sodomy, assault and battery with intent to rape, and assault and battery with intent to gratify. The sample does not include male victims or nonforcible, statutory offenses.

[3] The earliest year with complete records available was 1970. Because cases take up to two years to be adjudicated, 1975 was the latest year I could include in this study. I included 1973 cases because several changes in the organization of the criminal justice system occurred in that year. Examination of time shifts (LaFree, 1979) indicated few significant differences.

examine only arrest (e.g., Hindelang, 1978) ignore the possibility that variables which affect subsequent processing decisions may differ from those which affect arrest.

Variables

Table 1 shows the dependent and independent variables. The racial composition of the victim-defendant dyad is most central to the theoretical concerns outlined above. But only 11 (1.2%) of the cases involved white offenders and black victims.[4] The small number of these cases precluded meaningful analysis and they were excluded from the sample.[5] For the remaining 870 cases, race composition was dummy-coded as two vectors, with white intraracial assaults being the excluded category.

Dependent variables included in the analysis represent decisions made by (1) police, (2) prosecutor's office, and (3) criminal court. I included two police decisions: (1) *Arrest*, and (2) *Charge Seriousness*. I examined the arrest decision for all 870 reported assaults. And, for 339 suspects who were formally charged, I examined charge seriousness.[6] Charge-seriousness scores were assigned to each offense according to the mean prison term imposed by statute (e.g., 10- to 20-year sentence = a charge-seriousness score of fifteen; see LaFree, 1979).

After arrest, felony screeners in the Prosecutor's Office reviewed cases to determine whether they should be filed in criminal court. For 326 arrests, I examined *Felony Screening*, the decision to file or not file felony charges. Figure 1 shows that only 47% of the arrests for forcible sexual assault were filed as felonies.

For the 151 felony cases, I examined *Case Prosecution*, the decision to continue prosecution or dismiss (*nolle prosequi*) charges. Cases filed as felonies may be dismissed by the State or court at any

---

[4] Two (18.2%) of the 11 white suspects accused of sexually assaulting black women were arrested and had their cases filed as felonies. One man pleaded guilty; the prosecution dismissed the second case. The man who pleaded guilty received a 2-year executed sentence in a minimum security institution.

[5] Based on a study of rapes reported to Philadelphia police in the late 1950s, Amir (1971) concluded that rape was intraracial. Until recently, this conclusion was widely accepted. But several recent studies (e.g., Agopian et al., 1974; Curtis, 1976; Katz and Mazur, 1979; Law Enforcement Assistance Administration [LEAA], 1979) report much higher rates of black offender-white victim rape than those reported by Amir. Black suspect-white victim assaults were *nineteen* times more likely in this sample than white suspect-black victim assaults. Differences in crime reports by race have typically been explained by citing differential rates of reporting by black and white victims (e.g., Griffin, 1971; Savitz, 1973). But the recent availability of national victimization data (e.g., Hindelang, 1978; LEAA, 1979) indicates that differential reporting by race accounts for less of the discrepancy than has been commonly assumed. These findings emphasize the need for further longitudinal research on criminal victimization by race of the victim and offender.

[6] Thirteen men who were charged with an offense were not arrested, either because the charge was dismissed before they were apprehended or because the police were unable to locate them.

Table 1. Variables, Coding, and Frequencies

Variable	Coding	Distribution[a] N	%
Dependent Variables

[a] Variation in total number of cases due to missing data.

point, although dismissal was rare once trial procedures began. None of the 28 cases dismissed by the Prosecutor's Office at this stage was later refiled.

The remaining 123 cases were adjudicated through plea bargaining or trial. Two dependent variables measured conviction outcomes. *Trial* measured whether cases were fully prosecuted or resulted in guilty pleas. *Verdict* measured whether guilty or not guilty for all trials.

The court had primary responsibility for sentencing convicted offenders. Three variables measured sentencing outcomes. *Type of Sentence*, whether executed or nonexecuted, indicated whether the sentence included prison incarceration. Nonexecuted sentences represented some combination of probation, suspended sentence, and fine. While not included in earlier studies of sentencing, the place where an offender is incarcerated also reflects the severity of the sanction imposed on him. Incarceration in a local jail or minimum security institution generally represents a less serious sanction than incarceration in a medium or maximum security state penitentiary. Thus, for the 82 men who received executed sentences, *Place of Incarceration* measured whether they were incarcerated in the state penitentiary or elsewhere. Finally, for all men who were incarcerated, *Sentence Length* measured the sentence received.[7]

I identified independent variables from the literature on official reactions to rape (e.g., Sebba and Cahan, 1975; Amir, 1971; Holmstrom and Burgess, 1978). The analysis includes, in addition to race, the defendant's age and prior criminal record. Four variables indicate cases' legal and evidentiary characteristics. These are: (1) victim prosecution preference, (2) witnesses, (3) weapon, and (4) type of offense. Prior research (e.g., Skolnick and Woodworth, 1967; Black, 1971) suggests that more serious sanctions are likely when victims make clear their preference for prosecution of suspects. Although corroboration was not formally required in this jurisdiction, eyewitness identifications may clarify issues of consent and identification—issues that are especially problematic for sexual assault cases (Durham, 1952; Hibey, 1973; National Institute of Law Enforcement, 1977). Whether the assault involved a weapon relates both to the seriousness of the case and to the issue of consent. Likewise, type of offense—whether rape, or attempted rape—reflects the offense's seriousness.

The design utilizes the longitudinal data in two ways. First, each outcome is based on the results of the preceding outcome. For example, only cases filed as felonies are analyzed for prosecution or dismissal. Second, results of earlier decisions are incorporated as independent variables for later decisions. For all defendants who were charged with felonies, charge seriousness is included in subsequent processing decisions. For all convicted defendants, type of conviction—whether guilty plea or verdict—is included in the estimation of sentencing decisions. And, for the analysis of verdict, I include a binary variable—jury or bench trial—to control for type of trial.

RESULTS

Figure 2 compares percentage distributions of black suspect-white victim, black intraracial, and white intraracial incidents for the major processing decisions measured by the dependent variables. Figure 2 shows that, from case report to final sentencing, (1) the percentage of black intraracial assaults steadily declined; (2) the percentage of white intraracial assaults remained relatively constant; and (3) the percentage of cases involving black suspects and white victims steadily increased. The cumulative effect of these changes was substantial. Black men accused of assaulting black women accounted for 45% of all reported cases, but for only 26% of all men sentenced to the state penitentiary and for only 17% of all men who received sentences of six or more years. By contrast, black men ac-

---

[7] A forcible-rape conviction in this jurisdiction carries a penalty of from 2 to 21 years, or life imprisonment if the victim is under the age of twelve. Armed rape and armed sodomy carry sentences of from 10 to 30 years. Men convicted of forcible sodomy may be fined from $100 to $1,000 and imprisoned for from 2 to 14 years. Assault and battery with intent to rape carries a penalty of from 1 to 10 years. Punishment for assault and battery with intent to gratify sexual desires depends on the age of the victim. For victims between 12 and 17, the penalty is from 1 to 5 years. If the victim is under 12 the penalty is from 2 to 21 years. Kidnapping was frequently included with charges for forcible sex offenses. The penalty for kidnapping is life imprisonment. Indeterminate sentences were estimated by taking the mean of the high and low sentence (e.g., 2–21 = 11.5 years). Life sentences were rare, but, when encountered, they were "assigned" 40 years, as did Chiricos and Waldo (1975). For concurrent sentences, I included only the most serious charge.

	All reports	Arrest	Felony Charge	Full Prosecution	Conviction	Executed Sentence	Penitentiary Incarceration	Six + Sentence
BW	23.0	23.6	31.1	28.6	29.1	32.9	45.2	50.0
BB	44.7	40.8	38.4	39.7	35.9	35.4	26.2	16.7
WW	32.3	35.6	30.5	31.7	35.0	31.7	28.6	33.3
N	870	326	151	123	103	82	42	30

N indicates total cases reaching each processing stage. Two dependent variables, Trail (whether trial or guilty plea) and Verdict (guilty or not guilty for court trial) are subsumed here by Conviction. Variation in total number of cases reported due to missing data.

Figure 2. Percentage of Black Suspect-White Victim, Black Intraracial and White Intraracial Incidents for Eight Processing Stages

cused of assaulting white women accounted for 23% of all reported rapes, but for 45% of all men sent to the state penitentiary and for 50% of all men who received sentences of six or more years. Percentages of cases involving white victims and defendants fluctuated between a high of 35.6% (arrest) and a low of 28.6% (penitentiary incarceration). The percentage of white intraracial assaults resulting in prison sentences of more than six years (33.3%) was similar to the percentage of white intraracial assaults among all reported cases (32.3%).

In addition to the overrepresentation of black suspect-white victim cases and the underrepresentation of black intraracial cases, Figure 2 shows substantial variation in the size of percentage differences between processing stages. In fact, black intraracial incidents increased and black suspect-white victim incidents declined for the decision to fully prosecute.[8] Also, the percentage change between report and arrest for black suspect-white victim cases was small: .6%. The corresponding percentage change for black intraracial incidents was 3.9%. In sum, Figure 2 is consistent with the sexual stratification argument but suggests that race composition is differentially important across processing outcomes. I turn now to more elaborate measures of these relationships.

---

[8] Rather than dismiss cases outright against the wishes of the victim, prosecutors preferred to screen cases through different filing options. For example, prosecutors sent cases that they felt were less likely to result in conviction to municipal court bind-over hearings or to the grand jury. Each additional processing stage was perceived as a "dress rehearsal" to determine the strength of the victims' commitment to prosecution. Long prosecution delays give the victim ample opportunity to drop the case without requiring the prosecutor to deny, formally, her claim (for a similar observation, see Holmstrom and Burgess, 1978:127).

Table 2 shows the product-moment correlation (Pearsonian r) between the racial composition of the victim-defendant dyad and the nine sequential processing decisions. Also shown is the proportion of variance (r^2) in one variable that is explained by the other, as well as the sample size (N) for each outcome. Levels of statistical significance for computed correlation coefficients are shown where relevant.

As noted above, the sexual stratification theory predicts that assaults by black men on white women will result in the most serious sanctions (given that white defendant-black victim comparisons are not available). Generally, the results in Table 2 are consistent with this theory. Eight of nine outcomes indicate that black-white interracial assaults are likely to result in *more* serious sanctions for offenders; five of these relationships are statistically significant. Seven of nine outcomes indicate that black intraracial assaults are likely to result in *less* serious sanctions; one of these outcomes is statistically significant. Of the three outcomes which contradict the sexual stratification argument, none are significant.

Several of the relationships that support the sexual stratification interpretation suggest that the differences are not only statistically—but also *substantively*—significant (see Hagan, 1974:361). Assaults involving black offenders and white victims account for 27% of police charge seriousness, 9% of sentence length, 7% of place of incarceration, and 3% of felony screening and sentence type. Black intraracial assaults account for 7% of the variation in verdict and 3% of the variation in place of incarceration. By contrast, the most important of the contradictory findings (case prosecution for black-white interracial offenses) accounts for only 1% of the variance in that outcome.

Table 2. Product-Moment Correlations between Racial Composition and Nine Official Processing Decisions in Forcible Sexual Assault Cases

Table 2 shows why studies of official discretion that measure only the defendant's race (and not the race composition of the victim-defendant dyad) may be misleading. According to Table 2, black suspects were less likely to receive executed sentences when the victim was black and more likely to receive executed sentences when the victim was white. Of the sexual assaults, by black men, reaching this stage, 55% were intraracial. Thus, despite the significance of race composition for the decision, black suspects *as a group* are no more likely than white suspects to receive executed sentences (r = .06, n.s. at $p \leq .05$; not presented in tabular form). I turn now to the question of whether zero-order relationships apply when other attributes of the defendant—and the legal and evidentiary characteristics of the case—are considered.

Table 3 presents stepwise multiple correlations between the nine processing outcomes and the independent variables. In this phase of the analysis I am particularly interested in how early in the process racial composition variables enter each equation and, further, how much of an additional contribution each variable makes to the proportion of variance explained in the processing outcome. Table 3 shows R and R^2 values at each step in the process. Immediately below these values I list the variable added at each step. For example, prosecution preference (PREF) was the variable most highly correlated with the decision to arrest and it shows up in the zero-order column with an R = .39. By the fifth-order, weapon,

See Table 3 for item identifications.

eyewitness, type of assault, black-white interracial and black intraracial have been added, providing an $R = .42$ with six independent variables in the equation.

According to Table 3, the black-white interracial composition variable enters six of the nine outcomes by the second-order. The largest increment in explained variance (R^2) produced by adding race composition was for place of incarceration (R^2 increment = .06); followed by sentence length and case prosecution (R^2 increment = .04); police charge (R^2 increment = .03); and sentence type and felony screening (R^2 increment = .02). Overall, the inclusion of racial composition does improve the prediction of outcomes appreciably, with the greatest increases occurring for later, sentencing outcomes.

Table 4 presents the beta coefficients and standard errors for all variables which had significant net effects on processing outcomes. The prediction equations for two outcomes (case prosecution and trial) were not significant ($p \leq .10$) and results are not presented. Thus, there is no indication that racial composition had a net effect on these two outcomes. Racial composition had a significant effect on five of the remaining seven outcomes. Black offender-white victim cases were the most important racial consideration in all five of these outcomes. This variable enters the equation on the second-order for four of the outcomes and on the first-order for one outcome. All the significant results are in the direction predicted by the sexual stratification theory. Compared to other defendants, blacks who assault white women receive more serious charges, are more likely to have their cases filed as a felony, are more likely to receive executed sentences, are more likely to be incarcerated in the state penitentiary, and receive longer sentences. By contrast, black men charged with assaulting white women are *not* more likely to be arrested or found guilty in court than other men. And, contrary to the zero-order correlation results, black intraracial assaults have no effect on verdict, net of defendants' criminal record and age or whether incidents included weapons.[9]

Taken together, the results indicate that (1) processing decisions in sexual assault cases are affected by the racial composition of the victim-defendant dyad, (2) the cumulative effect of race composition is substantial, but (3) the importance of race composition varies across processing outcomes. Decisions in the criminal justice system may be classified according to whether their primary purpose is to determine (1) whether the defendant is guilty or (2) how serious the offense is. For example, arrest, verdict, and the prosecutor's decision to dismiss are all decisions related primarily to the suspect's perceived guilt.[10] By contrast, charge seriousness, sentence type, place of incarceration, and sentence length all measure the *seriousness* of the sanction imposed; they do not address the question of whether the defendant is guilty or innocent.

---

[9] Part of the reason that black intraracial assaults did not have a significant effect on verdict is due to small sample size (N = 50). In a related study (LaFree, 1980), which included different independent variables, assaults on black victims were significantly less likely to result in guilty verdicts.

Application of these two categories to the results indicates that race composition of the victim-defendant dyad has a greater effect on decisions measuring seriousness of the offense than on those indicating guilt or innocence. Racial composition was most important in predicting charge seriousness, felony screening, sentence type, place of incarceration, and sentence length. With the exception of felony screening, which relates to the issue of guilt (through dismissal) and severity (through reduction of charges), all of these decisions measure perceived offense seriousness. By contrast, racial composition was unrelated to arrest, case prosecution, trial, and verdict. With the exception of trial, which probably reflects the prosecutor's perceptions of the defendant's guilt and seriousness of the offense as well as the defendant's willingness to bargain, all of these decisions focus on the defendant's guilt.

It appears, then, that officials were reluctant to rely on racial characteristics to totally deny sexual assault complaints. By contrast, the victim and offender's race clearly affected official perceptions of offense seriousness.

SUMMARY AND CONCLUSIONS

The findings suggest, rather conclusively, that black men accused of sexually assaulting white women receive more serious sanctions than other sexual assault suspects. This conclusion is given added credence by the fact that racial composition had significant effects on five of nine processing decisions, net of evidence and legal severity measures. The results are generally consistent with the proposition that American society is characterized by a sexual stratification system which imposes more serious sanctions on men from less powerful social groups who are accused of assaulting women from more powerful social groups.

Two important differences between this and previous studies account for the results. Given the history of sexual segregation by race in this country, the racial composition of the victim-defendant dyad—and not the individual race of either offender or victim—is the most important racial consideration in processing decisions. Few previous studies have conceptualized the problem in this way. Also, the longitudinal nature of this research was unique. While evidence of discrimination by race in any single outcome was not overwhelming, the cumulative effect of race was consistent and substantial. Thus, studies examining only one or two processing outcomes (e.g., Chiricos and Waldo, 1975; Hindelang, 1978) may or may not support a view of discriminatory processing, depending on independent variables included, methods used, and specific outcomes examined.

Recent critics (e.g., Taylor et al., 1973; Chiricos and Waldo, 1975; Hindelang, 1978) argue that conflict theorists often do not include systematic empirical evidence to support their theoretical claims. Turk (1979:463) suggests that the validity of such partisan research cannot be assessed without sharing or rejecting its authors' ideological assumptions. This tendency has made conflict theory particularly vulnerable to empirically derived criticisms. These criticisms suggest that, for conflict theory to be viable, researchers must accumulate empirical evidence relevant to existing conflict propositions. The present study was an attempt to do this with regard to a specific conflict proposition: the severity of official sanctions imposed on men for the sexual violation of women will depend on the relative power of the victim and of the suspect, determined in part by the race of each. No conclusions can be reached about white offender-black victim cases. Nonetheless, the results indicate that official reactions (of criminal justice personnel) to rape are affected by the racial composition of the victim-offender dyad. Specifically, the results were consistent with the sexual stratification argument that more powerful groups in society enforce sexual-property rules, in part, by the differential application of the criminal law. And, more generally, the findings support conflict theory's longstanding claim that race and other legally irrelevant variables significantly affect official reactions to criminal offenses.

---

[10] The emphasis here is on *primary* purpose of the decision. Clearly, decisions like arrest (Piliavin and Briar, 1964) and verdict (Kalven and Zeisel, 1966) may reflect not only official presumptions of guilt or innocence but also perceived severity of offenses. The important distinction is that arrests and verdicts, unlike charges and sentences, cannot be more or less serious. By contrast, a more or less serious charge cannot distinguish guilty persons from innocent persons.

COMMENTS

THE NONINFLUENCE OF "FAMILY BACKGROUND" ON INTELLECTUAL ATTAINMENT*

(A CRITIQUE OF SCARR AND WEINBERG, *ASR* OCTOBER, 1978)

This critique places a recent article by Scarr and Weinberg (1978) into the eugenic or hereditarian school of studies which has examined the relative impacts of genetics and environment on IQ. Because of the tremendous policy implications of the resolution of the IQ debate, studies bearing on the question should be closely scrutinized for scientific rigor and objectivity. The Scarr and Weinberg article fails to meet rigorous scientific standards for several reasons. The theoretical concepts of genetics and environment are not explicitly and satisfactorily operationalized. The authors explain only a very small portion of the variance of the dependent variable, adolescent IQ, yet make conclusions based upon these insignificant results. Sampling bias undercuts environmental variation and jeopardizes external validity. The use of regression analysis is unclear, and correlation "heritability" analysis is arbitrarily and unfoundedly employed.

The perpetual debate in social science concerning the relative contributions of genetic inheritance and environment to individual development, in general—and to intellectual achievement, in particular—is not only intrinsically interesting but also has social policy implications. So great are the policy implications of this debate for the distributions of rewards within society that two clearly identifiable camps have emerged on the issue, despite a lack of rigorous application of scientific methodology in developing causal links and despite inconclusive data.

One school of authors of studies of IQ test scores and of factors causing score differentials between groups is the eugenic or hereditarian school and includes the works of Burt (1972; 1970), McDougall (1910; 1924), Davenport (1911; 1928; 1933; 1934), Eysenck (1971), Jensen (1969a; 1969b), and Reed et al. (1954). Into this camp also falls the recent study by Scarr and Weinberg (1978). This school argues that the impact of heredity upon IQ is great and exceeds the impact of environment upon IQ.

The other camp, called the environmental school, or the "naive environmental" school by its critics, remains skeptical that importance of heredity in IQ development exceeds the importance of environment. These authors cite the known deleterious effects (of malnutrition, disease, and deprivation due to poverty) upon IQ development as proof of the potency of environmental factors. Into this second camp fall on-going studies by the National Center for Health Statistics (Dupuy, 1977) examining links between family income and well-being and standardized tests and outcomes; Drillien's (1968; 1969) work examining social class, birth weight, and IQ scores in all-Nordic child populations; the explanation of group differences by Pasamanick (1951), Pasamanick and Lilienfeld (1955), and Pasamanick and Knobloch (1955); and the studies of Eichenwald and Fry (1969) of mental retardation prevention through the control of infectious diseases.

To the degree that the impact of genetic inheritance is greater than that of environmental factors, dominant groups in society may not only be expunged of guilt for disparities in intellectual attainment with minority groups but also alleviated of responsibility for compensatory education and other environmental mechanisms to close the gaps. Throughout history, the policy consequences of this intellectually unresolved question have already been great. Dominance of the eugenic or hereditarian school has helped to establish the racial immigration quotas in the U.S. Immigration Act of 1924. Between 1925 and 1941, the effect of this act was to reduce by over six million the immigration flow of groups labeled inferior by IQ test results, such as Jews, Italians, and Greeks. During the same time period in Germany and Europe, eugenicism (run rampant) contributed the horrific genocide of the Holocaust. In the United States, the Supreme Court doctrine of "separate but equal" education for blacks, in practice, was often separate, unequal, and yet justified by eugenic philosophy. More recently the environmental school has provided justification for compensatory education programs. Because of the obvious emotionalism of the debate and the magnitude of its outcome for public policy (both historically and in the future) academic research on the subject should strive for impeachable objectivity, avoiding conclusions which are unsupported by scientifically collected and analyzed data. Thus, each new piece of evidence bearing on the genetic inheritance-environment question should be scrutinized with great interest for scientific rigor and legitimacy. The Scarr-Weinberg (1978) article is no exception to this rule.

Scarr and Weinberg (1978) employ data collected on two samples of families: "biological" families, or those who have children by the birth process and whose offspring are consequently genetically related, and "adoptive" families whose children are adopted shortly after birth and are consequently not genetically related to the adopted parents or siblings. On the basis of analysis of these data, Scarr and Weinberg (1978:686) conclude

> it seems evident to us that the study of adoptive and biological families provides extensive support for the idea that half or more of the long-term effects of "family background" on children's intellectual attainments depend on genetic, not environmental, transmission.

This conclusion is incredible because none of their data, nor their analysis of the data, supports this conclusion. Furthermore, their tortuous analyses often obfuscate rather than clarify the evidence bearing on the basic question of genetic inheritance vs. environmental impacts. The conclusions that seem so evident to Scarr and Weinberg may not appear so obvious to others, for these reasons:

(1) Lack of explicit operationalization of theoretical concepts employed. What is being measured and tested in the Scarr-Weinberg (1978) research is ambiguous and slippery. While the authors begin their presentation by discussing the potential saliency of "family background" on intellectual attainment, they quickly switch to a discussion of "behavior genetic" methods and argue (p. 675) that "theoretically, regressions of adopted child outcomes on adoptive family characteristics will provide genetically unbiased estimates of true environmental effects in the population." While the regressions of adopted-child outcomes on adoptive-family characteristics do provide estimates of the environmental effects of the particular family characteristics measured and employed in the analysis, those family characteristics employed by Scarr and Weinberg are by no means inclusive of all relevant environmental effects. Indeed, the Scarr-Weinberg family variables are not even inclusive of all relevant familial environmental effects, as any attempts to measure the nature and intensity of nurturing or parental interest in child learning and intellectual attainment have been precluded. It is inappropriate to imply, as do Scarr and Weinberg, that, because the biological and adoptive families have slightly different R^2's in the regressions, genes (and not environment) are the source of family-background transmissions. More precisely, the authors never clarify what specifically operationalizes the concepts, "family genetic transmission" and "family environment transmissions." Are all family characteristics of the biological sample measures of family genetic transmission? If all of these variables (for example, father's education, mother's education, father's occupation, family income, birth rank, number of children, father's IQ, and mother's IQ) are indeed indirect measures of family genetic transmission in the biological family sample, why are they not more highly correlated? No correlation of family background characteristics exceeds .61 (Table 2, Scarr-Weinberg, 1978:678), the correlation for father's occupation and father's education, and most correlations of family characteristics in the biological sample are considerably less. One could argue that the relationship of father's occupation to father's education, for example, is a greater reflection of labor market demand than of family genetic transmission to adolescent IQ.

Whether the family background characteristics of the biological sample measure genetic transmissions, at all, is doubtful at worst and conjecture at best. If one concedes that at least some portion of these background characteristics measures genetic inheritance, the thoughtful reader must conclude that the family background characteristics for the biological sample in the Scarr-Weinberg (1978) study are a mixture of genetic and environmental transmissions, to the degree that genetic inheritance is measured at all. How the authors (p. 688) can then conclude, as they do, that these family background characteristics actually understate, rather than overstate, measured genetic transmissions is most perplexing.

(2) Very small explained variance in the dependent variable. Even to the casual reader familiar only with the rudiments of regression analysis, the aspect of the Scarr-Weinberg (1978) regression equations totally ignored by the authors but, nonetheless, so obvious and compelling, is the paltry amount of variance in the dependent variable, even by social science standards, explained by the independent variables they employ. The bulk of the article is spent arguing about the relative contributions of various independent variables, as well as the larger meaning of those variables for the gene-environment debate, when the reported R^2's show that all of the independent variables, combined, explain almost none of the variance in adolescent IQ. For the biological sample, the

highest R^2 obtained is .31, while, for the adoptive sample, an even lower .16 is the best obtained. Eight independent variables are used to obtain the model explaining 31% of the biological sample dependent variable variance, while 11 independent variables are used to obtain the model explaining 16% of the adoptive sample dependent variable variance. The obvious conclusion from these R^2's is that family background characteristics explain almost nothing about adolescent IQ variation—an incredible finding, which should have led the authors to note, as does this comment, the noninfluence of family background, at least as measured by Scarr and Weinberg, on intellectual attainment. With so little of the total variation in the dependent variable explained, to dwell at length (as do the authors) on the relative contributions of independent variables is to make "much ado about nothing." Despite R^2's, which never explain more than .31 of the variance, and despite the fact that these low R^2's were generated by mixture of environmental and genetic transmission measures, the authors blithely conclude that genetic transmissions account for 40% to 70% of adolescent IQ variation, a finding totally unsupported by the data.

(3) Sampling bias undercuts environmental variation and jeopardizes external validity. Random sampling is not employed to extract an unbiased sample for the Scarr-Weinberg (1978) study. Consequently, external validity—that is, the extent to which conclusions from the data can be generalized to a broader population—is limited. An analysis of the socioeconomic characteristics of both samples reveals that the largely self-selected samples were atypical of the general population in several potentially salient ways (for example, family income, parental education levels, etc.). Furthermore, the sampling procedure compressed the variance for environment, if socioeconomic characteristics were meant to measure environment. In essence, environment is held fairly constant at enriched levels for both samples. The subsequent finding that observed variation in the dependent variable is based on inheritance transmission is not startling, given that environmental variance was compressed, while genetic variance, especially for the adoptive sample, was not.

(4) Unclear use of regression analysis. If the authors intended for birth rank and family size to measure environment and for the remainder of family background characteristics to measure genetic inheritance for the biological sample, the rationale underlying the order in which the regression variables were loaded when analyzing the two samples is unclear. Standard procedure when a researcher is attempting to demonstrate the greater significance of one variable or set of variables, as Scarr and Weinberg implicitly if not explicitly are trying to demonstrate the greater potency of genetic transmission measures, is, first, to load all other independent variables. The variable or variables in which one has the greatest interest are then loaded in a second stage and are regressed into the residuals resulting from the first stage regression with all other variables. Not only do Scarr and Weinberg not follow this procedure but they also intersperse the "environmental" variables of birth rank and family size with "genetic" variables.

Second, the relative contribution (of any independent variable in a regression equation), toward explaining dependent variable variation, depends in part on which other independent variables are in the equation. Hence, one can compare independent variable effects across regression equations only if the exact same variables are employed in each equation, a procedure which is violated when additional variables for natural mother characteristics are loaded into the adoptive sample, in addition to other family background characteristics. A more appropriate comparison would be to compare the natural parent characteristics for both samples. While IQ scores may not have been readily available for natural mothers of adopted children, surely additional data on the natural mothers in the biological sample equivalent to the data obtained for natural mothers of adopted children could have been secured. However, only education was used for the latter group, and data on age and occupation which was collected for natural mothers of adopted children was not obtained for the natural mothers of the biological sample—a puzzling omittance, despite the fact that some mothers did not "work" (housewives would counter that they *do* work).

Third, because the signs of some regression coefficients are opposite from the direction anticipated, the authors ignore them in the analysis and discuss total R^2's. This is compounded, however, by the invalidation of cross-regression equation comparisons since family background characteristics are not measuring, by the authors' assertion, the same kind of transmissions in the two samples. Had equivalent measures been loaded for the two samples simultaneously, two-sample significance tests testing for the cross-equation differences in equations might have been conducted.

(5) Arbitrariness in correlation "heritability" analysis. Having failed with regres-

sion analysis to show that family background characteristics are salient to adolescent IQ., the authors launch into bivariate correlation analysis. That correlations among related family members of the biological sample are generally higher than the equivalent correlations among unrelated family members of the adoptive sample is interesting, although given that no control variables are employed, the possibility that spurious relationships (which might account for the higher biological-sample correlation) cannot be discounted. Then, however, on the basis that related family members share half of their genes, the authors arbitrarily decide to multiply the difference in correlations between samples by 1.6 (2., adjusted for "assortative mating") in a calculation that makes no theoretical sense. If adolescents in the adoptive sample share *no* genes with adoptive parents, and if biological sample adolescents share *all* genes with their natural parents, half with the mother and half with the father, then the difference between sample correlations alone should reflect genetic transmissions. If one is concerned about assessing the combined effect of both parents, midparent-child correlation differences would be more appropriate. Unfortunately, for Scarr and Weinberg (1978) mid-parent correlation differences are less than those obtained by the arbitrary multiplications.

(6) Unexplained sample differences. Scarr and Weinberg (1978) use enlarged samples for their correlation analysis. Given the ability of most regression programs to handle missing data in an airwise fashion, the rationale for the smaller sample sizes for the regression analysis are never explained.

In conclusion, what began as an interesting and imaginative piece of research did not live up to its original promise, primarily due to the lack of conceptual clarity in specifying the operationalization of key concepts and the authors' haste to prove the potency of genes.

CALLING ALL CAMPS! THE WAR IS OVER!*

(REPLY TO TAYLOR)

We appreciate the opportunity to address again the readership of *ASR* because the journal is central to the social sciences. Contrary to Taylor's (1980) muddled chauvinism, we propose that the Hundred Years War between nature and nurture is over. Her last-ditch skirmishes with genetic differences in behavior bear as little resemblance to current thinking in the social sciences as Shockley's sperm bank bears to contemporary thought in the biological sciences.

The problem we studied, the effects of "family background," is of concern to both social and biological scientists. A multidisciplinary perspective provides more complex models, which can lead to more complete explanations of the phenomena of parental influence on their children. Although there are advantages to viewing the same problem through several conceptual lenses, there are inherent difficulties in communication among people from several disciplines.

Taylor, like most social scientists, seems to be familiar with the concept of "family background," as it is used in the social sciences, to mean the total biasing effects of family membership on long-term outcomes of children. The focus of social science research is on *how much* bias, regardless of the sources of the bias. Most social scientists state or imply that family *environmental* differences are the source of "family background" effects.

Evolutionary biologists and behavior geneticists focus on *how* "family background" affects long-term outcomes of children. "Family background" is considered to include the effects of shared genes *and* shared environments. Taylor evidently does not understand that questions about sources of bias in "family background" for children who are genetically related to their parents must include a consideration of both genetic and environmental transmission from parent to child. In our study of adoptive and biologically related families, we attempted to answer both social and biological questions of "how much" and "how."

As psychologists, sympathetic to both social and biological perspectives, we are concerned with sources of individual differences and with the application of developmental psychology to the welfare of children and their families (e.g., Scarr, 1969, on birth weight and IQ; Scarr and Williams, 1973, on early intervention for low-birth-weight infants; Scarr, 1979, special issue of the *American Psychologist* on psychology and children's welfare; Scarr and Schwarz, 1979, on an early intervention program; Weinberg, 1979, on preschool intervention programs; Weinberg and Moore, 1975, on the evaluation of early intervention programs). We are committed to the *realistic* use of environmental interventions on behalf of children. An integral part of our conceptual framework is the understanding that human variation depends most often on both genetic and environmental differences.

Differences versus Development

A common error among social scientists is the failure to distinguish genetic and environmental sources of individual *differences* in behavior from the necessary roles of both genes and environments in behavioral *development*. One cannot assess the relative impact of heredity or environment on intelligence, per se, because everyone must have both a viable gene complement and an environment in which the genes can be expressed over development. No genes, no organism; no environment, no organism.

Behavioral *differences* among individuals, on the other hand, can arise in any population from genetic differences, from variation among their environments, or both. Imagine a population of genetically identical clones who are reared in family environments that vary from working to upper-middle class. Any behavioral differences among the clones would necessarily arise from developing within those different environments. Next, imagine a genetically diverse human population reared in laboratory cages. All members experience exactly the same environments. Naturally, all differences among these individuals are accounted for by their genetic variability. Notice that in the two fantasies, the organisms all have *both* genes *and* environments for *development*. In human populations, behavioral differences among people arise most often from both genetic and environmental diversity.

Theory and Operations

The theoretical bases of the research we (Scarr and Weinberg, 1977; 1978) reported are both population genetics and principles of socialization. Individual genetic differences in populations result from the evolutionary history of selection and variation and the transmission of genes from one generational pool to the next—from parents to their children. Concepts in population genetics were operationalized by studying families of different degrees of genetic relatedness—parents who transmit *half* of their genes to their children compared with parents who transmit *none* of their genes to their children. From the theoretical perspective of socialization, human parents provide the rearing environment for their children, regardless of their genetic relatedness. In adoption studies, however, the natural parents of adopted-away children transmit only their genes and not their social environments to their offspring. Thus, adoption provides a naturally occurring experiment for studying the effects of genetic variation and differences in socialization.

---

* Direct all communications to: Sandra Scarr; Department of Psychology; Yale University; New Haven, CT 06520.

The study of adoptive families provides an opportunity to estimate the effects of environmental differences on individual behavior. The fact that all adoptive families provide environments in the normal species range means that all adopted children's genotypes have the opportunity to be expressed (with genetically variable results). Adoptive parents transmit no genes to their children, although selective placement creates a very small ($\leq$.01) genetic correlation in adoptive families.

In our (Scarr and Weinberg, 1978) study, the biological families provided similar environmental opportunities for the development of their children. In biological families, however, each parent contributes a random half of his or her genotype to each child.

We (Scarr and Weinberg, 1978) operationalized the concept of genetic IQ differences in the population of upper-middle-class whites in the United States by comparing IQ resemblance among members of the biological and adoptive families drawn from this population. We compared pairs of family members who share about half of their genes with pairs who share virtually none of their genes. That is, by subtracting the IQ correlation of adoptive pairs from that of biological pairs, one subtracts the effects of environmental differences among families, measured by adoptive pair resemblance. The remaining surplus resemblance of biologically related pairs must be due to their greater genetic resemblance.

Because biologically related parents and children share about *half* of their genes, the remaining covariance is an estimate of about *half* of the genetic variance in the population from which the families were drawn. To estimate the *total* effects of genetic differences one must nearly double the difference between the correlations of biological versus adoptive relatives.

To calculate the genetic influence of *both* parents on each child (midparent-child correlation), one does not merely add up the genetic correlation of each parent with the child. Although the explanation of the midparent-child correlation is complex (see Falconer, 1970: 179–81; Munsinger, 1975: 624–5), the value is predicted by the term $\sqrt{2}\, r_{po}$, where r_{po} is the correlation of one parent with the child. The calculation is affected by the assortative mating of parents.

When the same parents have more than one child, the siblings share about half of their genes, because each child receives a random half from each parent. Some siblings will have by chance as few as 40% or as many as 60% shared genotypes.

When parents are not mated at random for a trait, as they are not for IQ, then the genetic correlations in biological families average more than 0.50, a fact that should be used to adjust estimates of genetic differences, as we did in our nonarbitrary multiplier of 1.6. The theoretical reasons for this multiplier are given in the lengthy footnote to Table 6 in the original (Scarr and Weinberg, 1978:685) article.

The midparent-child correlation is the best estimate of that portion of the genetic variance that is additive. Any effects of the parents' particular gene *combinations* are not included in the midparent-child or parent-child correlations. Thus, the differences between parent-child and midparent-child correlations in biological and adoptive families are measures of additive genetic variance or *narrow* heritability. Sibling correlations do include portions of the dominance and other nonadditive genetic effects. The estimate of *broad* heritability from the sibling correlation (0.61) was naturally larger than the estimate of *narrow* heritability from the midparent- or parent-child correlations (0.38–0.50). As we (Scarr and Weinberg, 1978) also indicated, sibs share a common rearing environment, not shared by parents and their children.

Representative Sampling

The population from which the adoptive and biological families were drawn was certainly not the entire United States white population. As we (Scarr and Weinberg, 1978) emphasized repeatedly (on pp. 675, 678, 686, 687, 688, and 689!), these families do not include lower class or economically deprived or abusive, neglectful environments. Nor are the families representative of racial minorities.

We agree with Taylor that the range of SES sampled by families in this (Scarr and Weinberg, 1978) study was necessarily restricted. Although the correlations among parental income, education, and occupational prestige were as high as those reported by studies with more representative samples (see p. 679), all of the children were reared in nondeprived, nonabusive environments. We agree that "the subsequent finding that observed variation in the dependent variable is based on inheritance transmission is not startling, given that environmental variance was compressed, while genetic variance, especially for the adoptive sample, was not" (Taylor, this issue, p. 857). The fact that the SES range of these families includes at least two-thirds of the United States white population in this age cohort makes the results of *some* interest, however.

Even within the range of working-class to upper-middle-class United States white families, the regression equations included only SES, parental IQ, sibling order, and family size measures of "family background," which "are far from perfect indices of children's experiences" (Scarr and Weinberg, 1978:689). But these are a more complete set than most social science studies of "family background" include. Furthermore, with the inclusion of a better set of such measures, "the amount of variance explained by *measured* rather than unmeasured environments might be increased in both kinds of families, but the genetic variance estimated would remain the same" (p. 689). Given the nature of the "family background" measures, "much of the variance is still unexplained, of course!" (p. 689).

Unmeasured Environments

The *unmeasured* effects of differences among family environments are, in fact, estimated as part of the total environmental variance by the adoptive family correlations. That is, the slight IQ resemblance between adoptive parents and adopted children and between adopted siblings necessarily means that 18 years of being reared in *different* family environments (measured and unmeasured) have only slight effects on the children's IQ differences. And it is from the comparison of correlations between biological relatives and correlations between adoptive family members (*not* from the regression equations) that we were able to estimate that 40% to 70% of the adolescents' IQ differences resulted from genetic differences among them (see Scarr and Weinberg, 1978: Tables 5 and 6). By contrast, the median correlation among adoptive parents, children, and siblings shows that only 9% of the IQ variance results from total differences among family environments in this SES range.

Regression Equations

Tables 3 and 4 presented three sets of comparable regression equations for biological and adopted adolescents' IQ scores, in columns 1–6. The first set, columns 1 and 2, gives the family SES variables usually considered in social science studies of "family background." For the adopted children, these measures index differences in only their family environments. For children biologically related to their rearing parents, the same SES variables represent both genetic and environmental transmission, as Taylor notes. "It is precisely the comparison of the equations for the adopted and the biological adolescents that permits an estimate of the relative importance of genetic and environmental differences in these indices of "family background."

In columns 3 and 4, sibling order and family size have been combined with the SES measures, but not in a stepwise fashion, as indicated by the changes in the coefficients on SES. The set of variables in these equations represents indices of both between- and within-family differences in "background."

In columns 5 and 6, the IQ scores of the rearing parents have been included with the previously mentioned variables. Parental IQ has rarely been available in social science studies of family effects on offspring, but is of great interest to behavior genetic studies of family effects. Again, it can be seen by changes in coefficients from the preceding columns that the variables entered the equation simultaneously to produce the best weighted combination of predictors.

The last two equations, columns 7 and 8, are unique to the adopted children, because their rearing parents are not their genetic parents. When some information about the adopted child's genetic background was introduced, the variance explained in the children's IQ scores was doubled over that explained by differences in adoptive rearing environments alone.

As Taylor notes, the measures of differences in rearing *environments* (both between- and within-family indices) accounted for only 7.5% of the adopted adolescents' IQ variance. By contrast, the *same* variables accounted for 31% of the IQ variance among biologically related adolescents, *because* parents in this SES range transmit their intellectual and social status achievements to their offspring by genetic as well as environmental means. Taylor's evaluation of the importance of 31% of the variance should be seen in the context of the expected R^2. Because parents and their children share neither all of their genes—nor all of their experiences—random, individual, genetic variance and experiences unique to individuals should account for at least one third of the IQ variance. We do not know of any studies of "family background" that accounted for more than 35% of the children's IQ variance (see Burks, 1928; Leahy, 1935; Sewell and Hauser, 1975; Duncan et al., 1972; Grilliches and Mason, 1972; Jencks, 1972; Jencks and Brown, 1978).

The "Same" Equations

Taylor (1980) requests comparable regression equations of child IQ on "family background" characteristics for adoptive and biological families, using pairwise deletion. We chose casewise deletion to avoid the suspicion that we had unfairly weighted partial information on employed mothers and natural fathers of the adopted children. Table 1 (herewith) shows comparable sets of equations for biological and adoptive families, including the educational, occupational, and age differences of rearing and genetic parents.

Three regression equations have been calculated, two that contain the same variables for the adopted and biological adolescents (rearing family only) and two that contain the same information—sort of. As Taylor (1980) requested, we show the regression of adolescent IQ on the educational, occupational, and age levels of both the rearing and genetic parents for both groups of adolescents. Unfortunately, as we reported in the (Scarr and Weinberg, 1978) article, there is insufficient information on the natural fathers and on the occupational prestige of employed, rearing mothers. Using pairwise deletion, the regression equations for child IQ on rearing family background are much the same, here, as they were in the original report. The inclusion of information about the natural mothers and fathers of the adopted children greatly increased the R^2 (from .037 to .483), but the latter is an absurd result because of the degrees of freedom. We (1978) were not hiding these results, but, rather, chose not to subject the readers to nonsense.

More informative are the zero-order correlations between adolescents' IQ scores and the background characteristics of the rearing and genetic parents. The adolescent IQ correlations with the educational levels of parents who are genetically related to their children reach statistical significance whether or not those parents had social contact with the children. In the biological families, where the parents are both the rearing and the genetic parents, mothers' and fathers' educational levels are related to their offsprings' IQ scores. Similarly the educational levels of the natural parents of the adopted children are correlated with the IQ scores of children whom they did not rear. In addition, natural mothers' occupational level has a small but statistically reliable coefficient with child IQ. No characteristic of the adoptive parents is significantly correlated with the IQ scores of the adopted adolescents.

Table 1. Standardized Regression Coefficients of Adolescent IQ on Demographic Characteristics of Rearing and Genetic Parents in Biologically Related and Adoptive Families (Pairwise Deletion)

	Adolescents' IQ Scores						
	Biological			Adopted			
			Zero-Order				Zero-Order
	(N)	beta	r	(N)	beta	beta	r
Rearing Parents							
Father's Education	262	.26	.25***	179	−.04	−.53	.07
Mother's Education	262	.17	.28***	188	.02	−.40	.09

R^2		.11			.037	.483	
Adj. R^2		.08			−.021	−1.238	
F		3.63			0.638	0.281	
df		6, 173			6, 99	10, 3	

* $p<.05$, *** $p<.001$.

We hasten to reiterate that the average level of IQ in the adopted group is higher than would be predicted from the intellectual levels of the natural parents because, as a group, they have been reared by adoptive families above-average in both SES and interest in children. Differences among adoptive-family environments in the range of working- to upper-middle class had negligible effects on differences in the adolescents' IQ scores, however.

Unexpected Results

"This study was designed to assess the cumulative impact of family environments at the end of the child-rearing period" (Scarr and Weinberg, 1978: 676). We expected to find that the differences among family environments would prove to be of *greater* importance by late adolescence than they had been for several samples of young adopted children (Burks, 1928; Leahy, 1935; Scarr and Weinberg, 1977; Horn et al., 1979). Just the opposite was found. In retrospect, our prediction seems unreasonable, because by early to late adolescence, children are subjected to many extra-familial influences (schools, peers, TV, etc.), and they are far freer than younger children to select their own environments. Parental influences are diluted by the more varied mix of adolescent experience.

Our interpretation of the results now emphasizes the kind of "niche building" that is called *active genotype-environment correlation* (Plomin et al., 1977). Different people select different aspects of their environments which they find compatible and then live in them, enlarge them, and deepen them. Part of what they bring to the selection of niches are the genetic differences as to what they are good at, what they enjoy, and what makes them comfortable. Adopted children, who are not genetically related to their parents or to each other, build niches that are correlated with their own genotypes but not with those of their family members. Biologically related children also build niches that are correlated with their own genotypes, but their choices continue to be correlated with those of their genetically related family members. We have found continuing resemblance in interests among the biological (but not among adoptive) family members (Grotevant et al., 1977), personality (Scarr et al., 1980), attitudes (Scarr and Weinberg, 1980), and specific cognitive skills (Carter-Saltzman, 1977). Genetic resemblance and genotype-environment correlations continue to affect IQ resemblance into later adolescence, whereas the effects of common family rearing environments wane.

Calling a Truce between "Camps"

We detailed here our theoretical framework and operational methods, drawn from both social and biological science in the hope that *ASR* readers will return to the original (Scarr and Weinberg, 1978) article to reconsider the evidence. Although it may be distasteful to some social scientists to acknowledge genetic sources of individual and SES differences, it appears to us important to recognize the biosocial nature of human variation.

We strongly oppose a eugenic strategy that interferes with people's civil liberties; we propose that understanding the nature of human variation will facilitate the design and implementation of effective environmental interventions to improve people's lives.

THE EFFECTS OF CROWDING FOUND IN THE TORONTO STUDY: SOME METHODOLOGICAL AND EMPIRICAL QUESTIONS*

(A COMMENT ON BOOTH AND EDWARDS, *ASR*, 1976)

Virtually all investigators agree that the evidence on the effects of overcrowding in the home has suffered from serious conceptual and methodological problems. Recently there have been two major studies, one in Chicago and one in Toronto, aimed specifically at overcoming these limitations. In the Chicago study we concluded that overcrowding had substantial effects (Gove et al., 1979), whereas the investigators of the Toronto study came to exactly the opposite conclusion. For example, in summarizing their results, Booth (1976:104) concludes that crowding has almost no detrimental effects and that "the minute effects of crowding revealed by our analysis indicate that we have a good deal of flexibility in housing people in dense environments . . . without fear that it will result in significant personal disorganization or in detriments in the health of the inhabitants." Given such diametrically opposed conclusions, it is desirable to determine if there is any basis for choosing one over the other. There are at least two important reasons for doing this. First, for purely scientific reasons, it is important to know whether crowding affects humans and, if so, under what condition and in what manner. Second, to the degree that social policy is based on social research, making a mistake on this issue can have undesirable consequences by legitimizing policies whose implementation would either waste a great deal of money (if crowding has no effects) or have a substantial negative impact on the quality of life (if crowding does have serious effects).

As the major paper for the Chicago study is readily available to readers of this journal (Gove et al., 1979), we will focus our comments on the Toronto study. Regarding the Chicago study, we will simply note the following points: (1) by and large, the characteristics of our sample correspond very closely to those of the households in Chicago both in terms of sociodemographic characteristics and in terms of levels of crowding; (2) our analysis is closely tied to the theoretical literature on the effects of crowding, paying particular attention to the subjective experience of crowding as indicated

---

by an excess of social demands and a lack of privacy; (3) to a substantial extent our measures of the subjective experience of crowding tended to "interpret" the generally significant relationship between our objective measure of crowding, persons per room, and the dependent variables; and (4) the relationships found with crowding generally were linear which, when combined with the characteristics of our sample, suggests that our results can readily be generalized to other populations.

In attempting to determine the reasons for the inconsistencies between our findings and those of the Toronto study, we have found three problem areas in studies done by Booth and his associates: (1) problems with the Toronto sample, in terms of its usefulness in a study of crowding, and the fact Booth and his associates misrepresent the degree to which it is representative of urban populations in general; (2) problems of analysis, specifically the measurement of crowding, the statistical procedures used in the analysis, and the interpretation of the data; and (3) problems concerning inconsistencies between findings and conclusions drawn from the Toronto study and conclusions drawn from studies done by Booth and his associates with other data sets.

I. The Sample

Instead of attempting to get a representative range of levels of crowding, the sample in the Toronto study was specifically drawn to obtain very high levels of household crowding. The 13 census tracts sampled in the Toronto study were, in the words of Booth and Edwards (1976:310), "selected for their potential in yielding a large number of families residing in dwellings in which the number of persons exceeded the number of rooms." These census tracts were also selected because they contained high rates of intact families with dependent children and persons who understood English (Booth, 1976:17). From these census tracts "nearly 17,000 screening interviews [were held which] yielded 862 eligible households. In 560 of these we were able to obtain interviews with one or both parents for a 65 percent completion rate" (Booth and Edwards, 1976:311). The households from which interviews were obtained were, in terms of social class, very homogeneous and were at the lower end of the class continuum. As Booth and Edwards (1976:311) state, "The majority (80 percent) of the household heads were employed in blue-collar occupations, typically ones requiring only modest skills. Only 23 percent had completed high school; however, more than half had completed the eighth grade." Furthermore, the characteristics of the respondents were limited by the fact that they all came from intact white families, the wife was under 45 years of age, at least one child was present, and all the respondents were able to converse in English.

The Toronto sample thus is comprised largely of households with extreme levels of crowding (approximately 50% of the respondents lived in homes with more than one person per room) and is very homogeneous in socioeconomic status and a number of other characteristics. Because the Toronto sample is so unrepresentative, not just of Toronto but of any typical urban population, it is not clear what the general implications of these data are (also, see Baldassare, 1979b). The homogeneity of the sample almost guarantees that there will be little variance and thus most relationships will be very modest.

Booth acknowledges that the sampling procedures were designed so that the number of persons sampled from houses where the number of persons exceeded the number of rooms would be equal to the number of persons sampled from houses where the number of persons did not exceed the number of rooms (Booth, 1976:19). This was apparently done so that there would be an adequate number of crowded persons. No theoretical reason is given for this decision, and the procedures used resulted in a sample comprised almost exclusively of persons residing in relatively crowded households. They claim that the sample is not seriously flawed and that it can be taken to be representative of urban households (Booth, 1976:39). However, Booth himself acknowledges that the average number of persons per room in Toronto is .58 (Booth, 1976:39). Furthermore, data from the United States, a highly urban country, show that Booth's sample is hardly representative of it either. For example, Gove et al. (1979) showed that the census data indicated that the median number of persons per room in 1970 for households in the United States was .54, and for U.S. central cities .51. The percentage over 1.01 persons per room in the United States in 1970 was 8.2%, and for central cities was 8.5%. As Baldassare (1979b) has shown, these percentages had probably declined by the time the Toronto study was conducted. If crowding is to a substantial extent culturally defined (as suggested in Gove et al., 1979; Baldassare, 1979a; Hall, 1966; and Booth, 1976:27), then in the absence of any other criteria, being crowded may be defined as being more crowded than is typical for other persons in one's culture. The validity of this assumption is suggested by the fact that both the Chicago study (Gove et al., 1979) and Baldassare's (1979a) secondary analysis of two national samples found that the relationship with persons per room and various indicators of "pathological" states was linear and there was virtually no evidence of a tipping effect associated with high levels of crowding (i.e., all households with more than one person per room). Treating household crowding as a phenomenon relative to one's particular culture, the less crowded half of Booth's sample contains a substantial number of crowded persons. For example, 52% of Booth's sample are supposedly uncrowded (Booth, 1976:Table 3.1). However, if one assumes that a crowded home is one which contains more persons than the average for households in Toronto in 1971 (.58 persons per room), and then one interpolates using data in Booth's (1976) Table 3.1 (and assumes that households are evenly distributed across the range of .40 to .75 persons per room), one finds that only 10.28% of Booth's sample are actually uncrowded, and 89.72% are crowded. Using Baldassare's (1980) cutoff for overcrowding (.60 persons per room) and the same interpolation technique employed above reveals Booth's sample to be only 11.43% uncrowded, and 88.57% crowded. If one uses .51, the median persons per room for the United States central cities, then Booth's sample is 6.29% uncrowded and 93.71% crowded. By virtually any reasonable standard of crowding, Booth's sample is overwhelmingly crowded, and contains a very small percentage of persons at the low end of the crowding continuum. In short, there is virtually no variance of crowding in the normal range (i.e., most of the variance in crowding is among persons already crowded). If our interpretation is correct then virtually all of his sample reside in crowded households and it is not surprising that he finds crowding has little effect.

Furthermore, homogeneity of the sample with respect to SES—80% blue collar, typically with modest skills (Booth and Edwards, 1976:311)—nearly eliminates any need for controlling for SES in the analysis. As Booth (1976:36) indicates, such a study design avoids the problem of multicollinearity, but it also makes it impossible to look at the interaction of crowding with SES or to control for the effects of SES, since there are virtually no middle class and upper class persons in the sample. Because most of the sample is crowded, this design contains a problem perhaps even more serious than having high levels of multicollinearity among one's independent variables, the problem that one's key independent variable (crowding) may not contain enough variance to test properly for its effects even at the zero-order level. That homogeneity is a problem is suggested by the fact that when we compare the total explained variance in Booth and Edwards (1976:315, 316) with the total explained variance on analogous variables in the Chicago study, we find that the Chicago study is explaining approximately twice as much explained variance as the Toronto study. This is perhaps pointed out most clearly by the two variables which are most similar: Toronto study (1) "times struck children," $r^2 = .06$, (2) played with children, $r^2 = .04$; Chicago study, (1) frequency of physically striking children $r^2 = .12$, (2) being supportive of child $r^2 = .09$.

The sample is even more problematic than it might at first appear. First, no data are presented on the response rate to the screening interviews. Second, because the researchers were sampling both parents in each household, the base for calculating the response rate should be the number of households times 2. If this is done, their actual response rate—Booth (1976:10) calls it a completion rate—after the screening interview with selected respondents was 49.7%, not 65% as stated (Booth:1976:20). Our response rate at this point in the interview procedure was 89.1%. Third, their sample is made complex by the fact that for some households they have two interviews and for other households one. In households for which they have two interviews, the data from the two interviews obviously should not be treated as independent. However, although Booth and Edwards (1976) report their response rate in terms of households, their analysis is limited to interviews, with each interview being treated as a separate independent unit.[1]

---

[1] One particularly troublesome aspect of their data is that, as Booth and Welch (1978) have shown elsewhere, for those households where they were able to obtain interviews with both the husband and wife and analyzed the items they felt would show at least a fairly high degree of consensus, they found that the level of correlation, whether dealing with shared events or similar attitudes, was generally quite modest (see their Table 1). One of their most extreme cases of a weak relationship was on a variable crucial to one of Booth's analyses dealing with crowded and sexual behavior (Edwards and Booth, 1977), where Booth and Welch (1978:28) found that the agreement between husbands and wives was only $r = .15$ on the item "(Did) lack of privacy ever prevent intercourse?" Booth and Welch (1978:30) indicated they "labored hard to find some correlation or predictions of consensus among marital partners . . ." but that ". . . substantive interpretations of these mixed findings (are) not plausible." It is clear that such negative findings raise questions

As noted, the 13 census tracts from which the samples were drawn were purposely chosen because they had the highest level of household crowding of all the census tracts in Toronto. Booth also had other very stringent criteria for his sample. As a consequence only 5.1% of the households screened met his criteria and in only 3.3% of the households screened were interviews actually obtained. As noted, his sample is very different from the general population in that his respondents tend to live in very crowded households, they have little education, household heads almost invariably had menial occupations, all respondents were married and living with their spouses, the wives were all under 45 years of age, and all respondents were white, able to converse in English, and in relatively good physical health.[2] On three occasions, however, Booth asserts the characteristics of the sample "do not limit the generalizability of findings to urban adult family members" (Booth, 1977:647; see also Edwards and Booth, 1976:75; and Booth and Welch, 1978:25 for a similar claim). In contrast, we would view the sample in the Toronto study as so atypical that it is very difficult to draw any conclusions regarding the general effects of crowding or, for that matter, other variables.[3]

II. The Measures of Crowding and the Interpretation of Findings

Most studies have used persons per room as their objective indicator of crowding. Instead, Booth and Edwards developed "objective" and "subjective" scales of crowding. They had no theoretical criteria for choosing the items in their scales. What they did was to run a set of items against their *dependent* variables and then select those items that explained at least 1% of the variance. This method of deriving their scale items is quite unconventional and, as noted by Booth (1976:24), would seem to "stack the deck" in favor of finding effects of crowding. Substantively, many of the items appear unrelated and, although they report the scale items had "a high degree of inter-item reliability for three of the four scales" (p. 812), the average correlations (r) are modest (.24, .26, .31, .02). As Booth and Edwards are concerned with the interitem reliability of their scales, we would suggest they use alpha coefficients rather than their idiosyncratic use of "average inter-item correlations."

Booth and Edwards (1976) state, "The simple crowding variable (persons per room and households per block) explains less variance than the crowding scales, which suggests that as crowding does have significant effects the scales tap them better." This statement is very misleading. For example, a comparison of the standardized regression coefficients in Tables 3 and 4 (Booth and Edwards, 1976:315–16), of persons per room and households per block with the object scales, taking size and direction into account, shows that 15 of the comparisons favor the traditional measures, 9 favor the scales, with 4 being ties. Similarly, a comparison of the number of zero-order relationships for the same variables shows that there are more statistically significant relationships in the predicted direction for the traditional measures (4 out of 32) than for their "objective" scales (2 out of 32). Other analyses show the traditional measures to be more powerful predictors than "subjective" or "objective" scales. The fact that, in combination, the scales explain more variance than the simple crowding measures might be expected because the scales contained both "objective" and "subjective" measures of crowding. Booth and Edwards (1976:317) argue that these scales tap very different phenomena. Thus, one would anticipate that a combination of the scales would explain more variance than measures that deal only with objective crowding. Booth and Edwards used 4 scales and 2 single crowding variables. The scales contain a greater proportion of instances where the relationship is in an unpredicted direction and the variance explained by the "incorrect" relationships comprises part of Booth and Edwards's explained variance for the scales. Thus, if one considers the number of independent variables and the direction of the relationships there is no evidence for be-

---

about survey data in general (a point made by Booth and Welch), but it is even more clear that they raise very serious questions about the quality of data in their particular survey, especially as it was not done by a survey organization with an established record for quality work.

[2] Booth (1977:647) indicates that "of the 302 households in which interviews cannot be obtained, 72 individuals were too ill to be interviewed, 76 refused to be interviewed and 214 did not speak English well enough to complete the interview."

[3] Not only is this sample grossly unrepresentative of any typical urban population in North America, it is also thoroughly unrepresentative of the population in the census tracts from which it was drawn. As Booth (1976:17) notes, "The proportion of households in which people exceeded rooms ranged from 12 to 28 percent of the units in selected tracts," while 48% of the households selected contained more than one person per room. We might further note that if one scans the column in the *City County Data Book* (U.S. Census, 1972) showing the percentage of households in U. S. cities with more than 1.01 persons per room in 1970, such percentages *rarely* exceed 11%.

Table 1. The Comparison of the Proportion of Zero-Order Correlations That Are Statistically Significant (.05) for the Crowding and Social Structural Variables in the Toronto Study

	Social Relations		
	Social Structure		Crowding
	# Sig./Total #		# Sig./Total #
Education	1/16	Persons/room	2/16
Occupation	0/16	Household Objective	2/16
Age	3/16	Household Subjective	3/16
Total	4/48	Total	7/48

From Booth and Edwards (1976:314).

lieving that the scales individually explain more variance than the simple crowding variables. Apparently, the items analyzed to develop their scales were not well chosen. In short, not only are the scales atheoretical and improperly derived, but they appear to be worse predictors than the traditional measures of crowding.

Booth and Edwards (1976:317) state "we might hypothesize that the greatest predictor of the subjective crowding would be objective crowding itself." They find, however, that "the actual correlations between the objective and subjective crowding measure are quite modest." Puzzled by this lack of relationship they eventually conclude that the experience of crowding is largely unrelated to actual crowding. Given that we found persons per room strongly related to the subjective experience of crowding (Gove et al., 1979), we suspect that their general lack of relationship is a consequence of their methodology and the fact that their subjective scales do not focus on the theoretically important dimensions of subjective crowding, demands, and privacy.

As to a very concrete issue, what exactly are Booth's "modest" relationships between objective and subjective crowding? It is hard to tell. In Booth and Edwards (1976:317) they are presented as .12 for females and .19 for males, but in their Table 2 (p. 314) they are presented as .10 for females and .22 for males, and in Booth (1976:32) as .16 for females and .14 for males. This is not the only case of carelessness in the presentation of data. For example, Booth and Edwards (1976:312) state "the relatively high .51 zero-order correlation between the objective crowding scales and the people/room variable and a correlation of a similar magnitude (.49) between the neighborhood objective scale and the household/blocks also attest to the reliability of the study" (Booth, 1976). However, a simple look at Table 2 (p. 314) shows that these are the values for *women only* (for men, they are .36 and .57, respectively).

Fischer et al. (1975:412) have forcefully argued that there should be some theoretical rationale for linking a particular measure of crowding to a particular "pathology." Throughout the papers and the book describing the Toronto study, the effects of neighborhood crowding and household crowding on the pathologies are combined in the discussions. Booth and Edwards (1976:311) admit that their study of the effects of neighborhood crowding on many of the variables they are considering is very unusual and they present no rationale for why one would expect neighborhood crowding to be linked to their dependent variables. Such a link is not obvious. In fact Galle et al. (1972) showed neighborhood crowding was unrelated to "pathological" behavior, a finding that has been subsequently replicated in a number of studies. Why, for example, would one anticipate the item, "Are the neighborhood stores in which you shop too crowded?" to be linked to poor family relations or physical health (particularly after controlling for socioeconomic and ethnic variables)? The fact is that, in their study, neighborhood crowding is never related to the dependent variables, but the lack of a relationship (which is to be expected) is included as part of the finding that crowding has little effect. For example, Booth and Edwards (1976:317) state in their report on family relations,

> out of the 84 possible relationships (six crowding measures, the two sexes, the seven dependent variables) only 11 are significant at the .05 level. Ten of those relationships show crowding to have adverse effects and one shows it to have positive influences.

But 28 of the relationships deal with neighborhood crowding, none of these is statistically significant, and none should have been included in the analysis. Thus, the number of relationships considered should be 56 and not 84; then the effects of crowding would appear to be somewhat stronger than the discussion by Booth and Edwards implies.

Now let us turn to something that borders on being inexplicable and theoretically should be expected to mask the effects of crowding. In the table discussed previously, Booth and Edwards (1976:315–6) present the relationship between six crowding variables and seven dependent variables using Betas produced after controlling for the effects of age, socioeconomic status, education and ethnicity. These controls are, of course, entirely proper. However, in each of their analyses they also control for the effects of the five other crowding indexes. To the extent that one measure of crowding relates to another measure of crowding (i.e., they both measure crowding) Booth and Edwards have eliminated through controls the effects they are attempting to investigate. This tactic, which is virtually guaranteed to show crowding has little effect, is used throughout the analysis of the Toronto data. (Note: Because of the ineffective way crowding has been measured, as we have explained, this totally inappropriate analysis is not as damaging as one would expect on theoretical grounds.)

As is apparent, the Toronto study suffers from serious problems of sampling, measurement, and analysis, and the conclusion drawn by Booth and his associates, that crowding has very little effect, rests on an extremely tenuous base. Since we do not have access to the data, perhaps the best way to evaluate whether the Toronto data demonstrate that crowding is unimportant is to compare their strength with variables typically thought to be important predictors. With the Toronto data, this can be done by comparing the proportion of zero-order correlations that are statistically significant for the crowding and the social stratification variables. These comparisons, using social relations and health as dependent variables, are presented in Table 1. From these data it is obvious that, while few of the relationships are statistically significant, the crowding variables have a higher proportion of significant relationships.[4] Thus, for this very atypical sample, household crowding has at least as much, and possibly more, effect than some of the traditional demographic variables considered by sociologists. In short, a careful scrutiny of the Toronto study shows that the data, in spite of the conclusions drawn by Booth et al., do not conflict seriously with the Chicago study.

III. Other Findings by Booth Concerning Crowding

Anyone reading the work by Booth and Edwards (1976) and the other papers from the Toronto study (Booth, 1976; 1975; Booth and Cowell, 1976; Edwards and Booth, 1977; Johnson and Booth, 1976) would conclude that Booth and his colleagues believe that crowding has very little if any pathogenic effect on human behavior. There is, however, a "second" Booth who strongly argues for the effect of crowding. Booth and Welch (1978) looked at the relationship between area density and civil disorder using 65 cities as the units of analysis; they found "households of crowding and to a less extent, areal density, are linked to the emergence of civil strife" (Welch and Booth, 1974:153), and they emphasize that crowding has a much greater explanatory power than do measures of industrialization, urbanization and discrimination. Subsequently Booth, Welch and Johnson (1976) conducted a study of crowding and urban crime rates and found a small but significant relationship between density and a variety of personal and property crimes. In a later paper, Edwards and Booth (1977:792) referred to this study as evidence for believing that crowding had significant pathogenic effects. And in a more recent paper, Booth, Johnson and Choldin (1977) attempted to evaluate the validity of official crime statistics and victimization crime rates by seeing if a set of independent variables predicted the same pattern for the two sets of rates. Their set of independent variables excluded a variety of variables one might expect to be included (e.g., they have no measure of income) but included both population density and household crowding on the grounds that the evidence indicates there are substantial reasons for believing them to be causally related to crime (Booth et al., 1977:189).

This second Booth, who believes in the pathogenic nature of crowding, seems totally unrelated to the first, who claims that crowding has virtually no effects. References in the articles of the first Booth do not include citations to the second Booth and vice versa. Nowhere is there any indication that Booth sees any contradiction in his results or any need to attempt to reconcile them either theoretically or empirically. This is particularly puzzling in that both sets of works were being produced over the same period of years. Thus, if one is to look at Booth's works in totality (1) one cannot tell if he believes crowding has an effect or not and

---

[4] The direction of these relationships was not taken into account. The one relationship with education is inverse. We did not know what direction to expect with age. Six of the seven relationships with crowding on social relationships show it as having a detrimental effect. We would note, if ethnic status is included, the effects of the social structure would appear to be somewhat stronger. However, "ethnic status" does not measure one's ethnic group but, rather, it answers whether or not one has recently migrated to Canada—which would appear to involve a whole set of problems dealing with adapting to a foreign culture.

(2) his work, being almost totally contradictory, does little to settle this empirical question. It seems to us that, even if an investigator cannot reconcile contradictory findings, he or she is at least under a strong obligation not to obscure the fact that the findings are contradictory. We feel it would be very useful if Booth and his colleagues would either attempt to reconcile his contradictory findings and stated conclusions or provide the reader with some guidelines on how to interpret their contradictory results.

We would note the most recent publication by Booth (Duvall and Booth, 1978) does not fit into either of these patterns. That paper has to do with aspects of the housing environment, one of which has to do with "perceived space and privacy problems." All the items in the perceived space scale were drawn directly from Booth's subjective crowding scale, and lack of privacy has been consistently treated throughout the literature as a consequence of crowding. Duvall and Booth find these items are related to poor mental health. Thus, in this case the Toronto data appear to be related to crowding; however, Duvall and Booth (1978:fn. 3) deny this, because in their words: "This is not a study of the effects of crowded conditions."

In summary, whether one looks simply at Booth and Edwards or at the whole set of published works by Booth and his associates on crowding, no reason is evident for concluding that crowding does not have important effects.

REPLY TO GOVE AND HUGHES*

Contrary to the Gove-Hughes allegation, there is only one Alan Booth, and that is the Alan Booth who, along with his colleagues, has pursued many avenues in an attempt to learn how crowding might influence pathology.

---

* Address communications to: Alan Booth; Dept. of Sociology; University of Nebraska; Lincoln, NE 68588.

Gove and Hughes fail to distinguish between those studies using aggregate data and those relying on individual-level information. Like many investigators (including Gove), we explored the effects of crowding using cities (and even nations) as the units of analysis before individual-level data became available. As we point out (Booth and Edwards, 1976:309), the use of aggregate data may be the source of some of the conflicting findings that characterized early crowding research. All of the later studies using individual-level data have consistently confirmed the findings of the Toronto study. And, as we point out elsewhere in this issue, so does the work of Gove and his colleagues (1979).

Gove and Hughes, nevertheless, raise several issues regarding the Toronto investigation. Specifically, they claim that the Toronto study has the following limitations: (1) there is little variation in the crowding variables; (2) the sample is homogenous with respect to a variety of background variables; (3) the interview completion rate is lower than reported; (4) the crowding scales are atheoretical and improperly derived; (5) conventional crowding measures are superior to the scales used; (6) the analysis is flawed by inconsistencies in the correlations between the same variables and the improper use of controls; and (7) the crowding measures have stronger effects than the background variables. Not only are their assessments incorrect, but the purported limitations have little relevance for the size of the crowding effects found.

The keystone of Gove and Hughes's criticism is their claim that the Toronto sample is so homogenous with respect to household crowding that the effects of this variable are greatly underestimated. This would be correct if either of two things were evident: first, that the effect of crowding on pathology conformed to a "tipping point" rather than a linear model (Figure 1A illustrates the linear model, while Figure 1B shows the "tipping point" model in which the effect occurs at a certain point on the crowding continuum); or second, that the disproportionate sample used in the Toronto study explains less variance in pathology than when it is weighted to return the sample to proportionality. Neither is true. Gove and Hughes assert, and we agree, that the effect of people-per-room on assessment of pathology is linear across the range of the crowding measure with no evidence of a "tipping point." While the Toronto study crowding measures fall at a higher point on the continuum (range b in Figure 1A), this would make a difference only if most of our sample was above the "tipping point." As neither the Chicago data, the Toronto study, nor any other analyses we know of support the "tipping point" model, we can discount this factor as a source of bias in the Toronto study. The only other way this could be an important consideration is if the variance caused by people-per-room was diminished by the sampling procedure. The disproportionate sampling procedure used in the Toronto study did indeed affect the distribution of the people-per-room measure, since the sample was drawn to ensure that half the sample came from households in which there was more than one person-per-room. Comparison with the variance in people-per-room computed with the sample weighted to proportionality, however, found that our sampling procedure increased—not decreased—the variance in people-per-room. We can perform a simple test of the consequences of the disproportionate sampling for the relationship between crowding and pathology by comparing the amount of variance crowding explains in a representative linear dependent measure computed for the disproportionate sample with the amount explained when weights are used to return the sample to proportionality. The explained variance with the disproportionate sample used was 3.4%. Weighted to proportionality it decreased to 2.8%. If we had sampled proportionately and thus moved our measures toward the national median, it would have decreased the variance in our crowding measure and reduced, not increased, the effects.

The Gove-Hughes argument that our estimates of the effect of crowding on pathology are reduced because our sample is homogenous with respect to the background variables is equally vacuous. If our interest was to show the relationship between, say, education or occupation and pathology, such a statement would have merit. However, our intent, as was the case with the Gove et al. (1979) study, was to find the effect of crowding on pathology net of the spurious effects introduced by the background measures. The relative heterogeneity of the background variables is irrelevant, as they are controlled in the analyses of both the Toronto and Chicago data. Gove and Hughes's "illustration" of the problem, where they compare similar measures in both studies, can be easily turned around to verify the validity of our procedures. They show the total variance explained by a combination of crowding and background variables for two measures that are similar in the studies and conclude that the Chicago study is explaining "twice as much variance as the Toronto study." While this is true for total explained variance, the amount uniquely contributed by the crowding measures, beyond that explained by the background variables, is similar. After removing the effects of the controls, the crowding measures account for around 1% of the variance in each of the variables in the Chicago study and they explain 0% and 3% in the Toronto investigation. Thus, the Chicago study does no better at finding an effect net of the background variables. The only consequence of the greater heterogeneity in the Chicago study is that the background variables do explain more variance in pathology. The impact of crowding is unaffected.

The interview completion rate charged to be inaccurate was calculated by dividing the number of households where at least one interview was obtained by the total number of eligible households. We did not obtain full interviews from both husband and wife in all cases; therefore, if one based a completion rate on the number of people, it would be somewhat lower. The household is, however, the more suitable unit upon which to base the completion rate calculation for two reasons: (1) the environment and circumstances shared by the husband and wife are common ones; and moreover (2) the analysis of children was based on information provided by either the husband or the wife. More importantly, the completion rate is not a factor that would bias the results because our analysis shows that the characteristics of households from which interviews were obtained did not differ from those where they were not obtained. In short, the Gove and Hughes claim has no bearing on the results of the study.

Likewise, contrary to their critique, the development of the crowding scales was neither atheoretical nor improper. While the data collected allowed us to test a number of theories, the predominant one guiding the study was a stress model hypothesizing that space limitations foster disturbances in family relations. If the creation of the scales were atheoretical, we would have been much less selective in our choice of measures. As it was, we chose only those most reflecting space limitations. We included a refinement of the people-per-room measure—the number of hours the respondent was at home and awake during which the number of people was equal to or exceeded the number of rooms. The procedure used in developing the scales was similar to a canonical scaling model (Van de Geer, 1971:83–92) in which weights for items are developed on the basis of their association with a set of dependent variables, standard procedure for selecting a set of independent items that maximize the relation with a set of dependent measures. The procedure used to derive the scales was, therefore, not improper.

Gove and Hughes attempt to show that our scales are no better than conventional measures of crowding. In comparisons of the standardized regression coefficients between crowding and pathology they find many of the traditional measures to have higher coefficients. However, the average number of points by which the coefficients differ is only .06, with the vast majority equal to or below this number. It is difficult to attach much meaning to differences so small. Regardless of which measures one might consider superior, this does not alter the size of the effect of crowding on pathology as assessed by either measure. The effects, like those found in the Chicago study, are small or simply nonexistent.

The allegation of inconsistencies in the correlations reported in our study is another in-

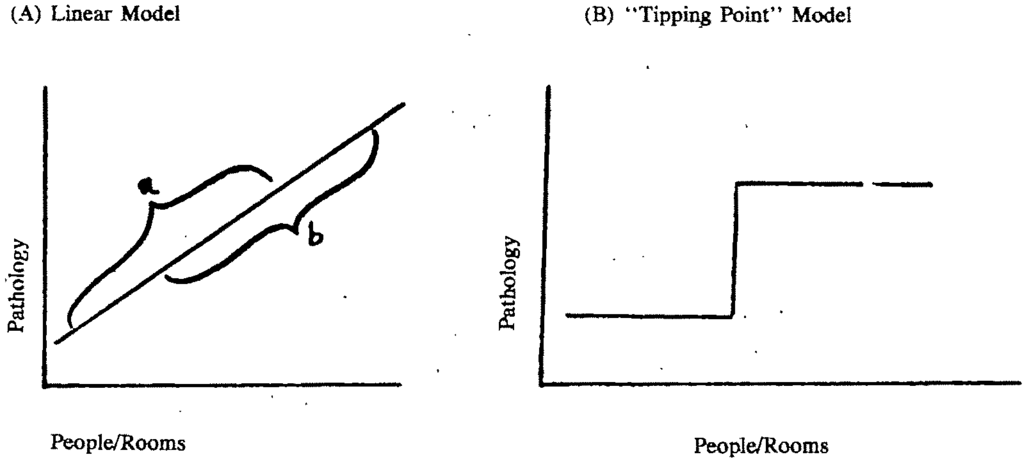

Figure 1. Linear and "Tipping Point" Models Relating Household Crowding and Pathology

stance where Gove and Hughes are "grasping for straws." The correlations showing the relation between objective and subjective crowding reported in Table 2 of our (1976) paper were, as stated, generated by a listwise procedure. The correlations presented in the footnote on page 312 of that paper were not. The listwise procedure accounts for the slight differences. Again, this claim has no bearing on the size of the effects observed or the conclusions one can draw from them. Neither does the fact that all of the crowding indices were included in the regression equations simultaneously have a bearing on these matters. The results are not affected because the scales are not highly correlated as the critics themselves note.

Finally, we are struck by the inconsistency of Gove and Hughes's arguments when they point to the fact that our crowding measures have stronger effects than the background measures. On the other hand, they use the lower variance of some of our background variables as a criticism of our study. On the other, they try to use the consequence of the lower variance (lower zero-order correlations of background variables with pathology measures) as an indication that we have stronger crowding effects than reported. Not only are these arguments inconsistent, they are unfathomable.

Gove and Hughes write: ". . . a careful scrutiny of the Toronto study shows that the data . . . do not conflict seriously with the Chicago study." We thoroughly agree. As we have just shown, nothing Gove and Hughes suggest in their comments on the Toronto study successfully challenges the size of the effects found. In instances where the crowding measures used in the Toronto and Chicago studies are similar, the effects are comparable. If the magnitude of the effects are similar, why do the investigators in these two studies reach such different conclusions? As we point out elsewhere in this issue, it is when Gove and his colleagues use a measure of crowding that is neither conceptually nor analytically distinct from their dependent variables that larger effects are detected. Such contamination, we surmise, led Gove and his colleagues to their misguided conclusions. We can only hope that their exaggerated views of the magnitude of crowding effects will not mislead public policy.

IN PURSUIT OF PATHOLOGY: THE EFFECTS OF HUMAN CROWDING*

(COMMENT ON GOVE, HUGHES, AND GALLE, *ASR*, FEBRUARY, 1979)

All too few field studies exist concerning the effect of household crowding in urban areas. Those using statistical techniques controlling for possible confounding factors, such as socioeconomic status, are even more rare. Therefore, the addition of the report by Gove, Hughes and Galle (1979) is worthy of note. Drawing on interview data from a large (2,035) sample of Chicago residents, the authors examine the effects of household crowding on a wide range of dependent variables, purportedly indicating its adverse effects. Among the pathological consequences catalogued by the authors are poor mental health, withdrawal, a lack of effective planning, deteriorated physical well-being, poor familial relations and child care. In sum, the authors conclude (p. 79), ". . . it is time to turn away from the question of whether it [household crowding] ever has effects to the study of the factors which magnify or minimize its effects." Obviously, such a conclusion has broad implications for housing and land-use policy.

A careful review of the Gove et al. (1979) report reveals, however, some severe problems, making their conclusion premature, if not misguided, and, in a more general sense, misleading.[1] Close examination of their data suggests a contrary conclusion, one quite similar to that of field studies conducted in Hong Kong (Mitchell, 1971) and Toronto (Booth, 1976; Booth and Cowell, 1976; Booth and Edwards, 1976; Booth and Johnson, 1976; Edwards and Booth, 1977; Johnson and Booth, 1975).

[1] Part of the authors' justification for their research is that most prior studies are inconclusive. In particular, they suggest (Gove et al., 1979:60) that the sample used in the Toronto study (Booth, 1976) is ". . . so atypical and homogenous and the measurement and analysis so flawed that it is difficult to draw any conclusions about the effect of crowding. . . ." As these are undocumented assertions, they will not be addressed here but will be refuted in a suitable forum where the charges are developed and fully specified.

The difficulties in accepting their conclusion are several but begin most fundamentally with the conceptualization and measurement of crowding. The experiential crowding variables used (lack of privacy and felt demands) are, or should be, conceptually and analytically distinct from the measures of social pathology. Yet no evidence of such a distinction is reported by Gove et al. (1979). They claim that the beliefs that one does not have sufficient privacy and that others are too demanding are crowding measures. However, they may well be measures of poor mental health. How then are we to interpret the relationship of insufficient privacy and felt demands to irritation, alienation, a lack of positive effect, low self-esteem, and unhappiness—the dependent measures of mental health used by the investigators? A person who feels unloved, irritated, alienated, self-deprecatory and unhappy could well manifest these feelings in a positive response to the question: "At home, does it seem as if you can never be by yourself?" (one of the privacy measures); or the item: "Does it seem as if others are always making demands on you?" (one of the demand measures). In short, there is a strong possibility that the causal direction is the reverse of that proposed. Poor mental health or deteriorated social relations (the indicators that Gove and his colleagues (1979) use as dependent variables) could very well lead individuals to feel that people are altogether too demanding and not granting them sufficient privacy (the factors they use to assess crowding) or, just as likely, the feeling that people are too demanding may be another indication of poor mental health.

If the experiential measures of crowding are indicators of poor mental health, the basic regression model used by Gove et al. (1979) is misspecified and the estimates biased. A model we think better fitted to the Chicago study data along with the model Gove and his colleagues present in their paper is shown in Figure 1. While we cannot fully estimate our alternative model, sufficient information is available to show that our model is better fitted to the data than is theirs.

Using the basic theorem of path analysis, we can trace through the paths to estimate the expected values of the correlations between crowding and pathology.

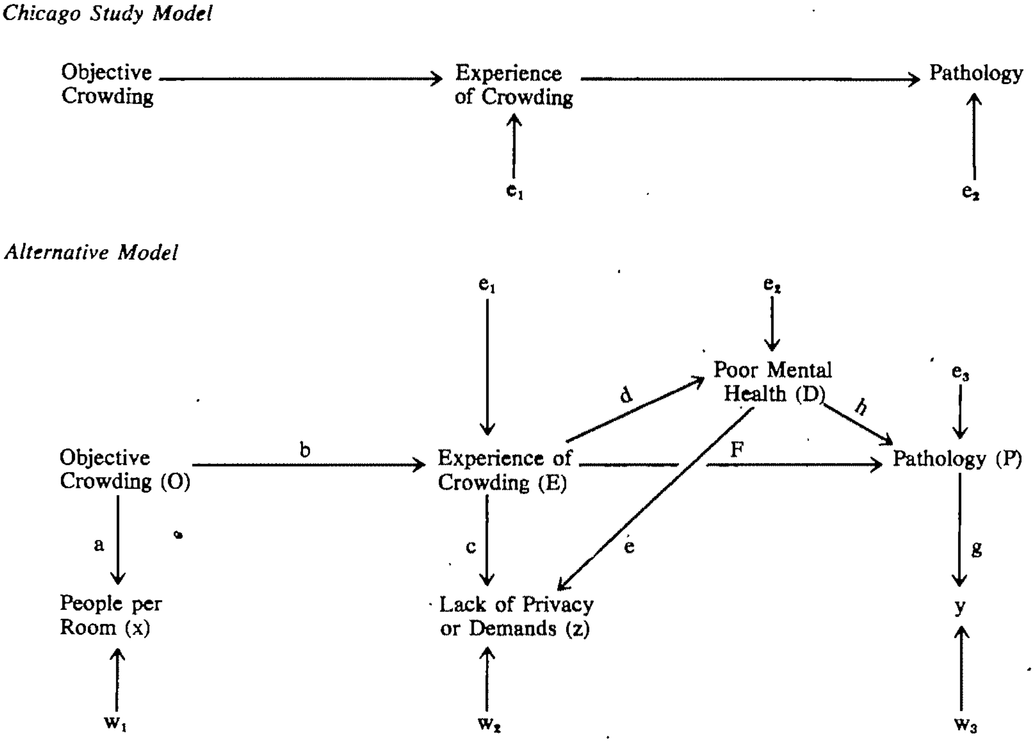

Figure 1. Two Alternative Models of Crowding Effects

$$r_{xy} = abfg + abdhg = abg(f + dh)$$
$$r_{zy} = cdhg + cfg + ehg = cg(f + dh) + ehg$$

The magnitude of path e indicates the degree of bias in the measure of crowding experience. If no bias were present (e = 0), then the term ehg in the equation for r_{zy} would also be equal to zero. It can be shown that, if no bias is present, then the ratio of the two correlations is

$$\frac{r_{xy}}{r_{zy}} = \frac{abg(f + dh)}{cg(f + dh)} = \frac{ab}{c}$$

If poor mental health does not bias the measure of crowding experience, then the ratio of the two correlations should always be the same (within sampling error), regardless of the values of f or dh, provided the model is correctly specified. However, if, as we hypothesize, e is nonzero and positive, then as the size of path h (poor mental health on the measure of pathology) increases, it will increase r_{zy} but have no effect on r_{xy}. Thus, the ratio ab/c decreases as the relationship between pathology and poor mental health increases. For each measure of crowding and pathology we computed ratios using the beta coefficients generated from the regressions which included the control variables but not the crowding measures.

Excluding three ratios with negative values (their interpretation is ambiguous), the smallest ratios from both the demands and privacy variables analyses were those for the following pathology measures: involved in arguments; not enough sleep; catch a bug from others; not cared for by others; psychiatric symptoms; nervous breakdown; and get along with others—all of them variables closely tied to the conceptualization of poor mental health. The average size of the ratios was .22. The largest ratios were those for the indicators of positive marital relations; child care; alienation; mental health balance; overall health; and physical violence—variables that cannot be readily viewed as indicators of poor mental health. The average size of these ratios was 1.63. The low ratios stemming from the way the mental health measures were analyzed indicate that the experiential indicators of crowding are also measuring poor health. Therefore, it appears that the experiential measures cannot be used to assess the effect of crowding on pathology when using the mode of analysis (multiple regression) selected by Gove and his colleagues (1979).

It could be argued, however, that the ratios are varying because of the presence of direct paths from people-per-room to the pathology measures. Such paths would explain some of the variation in the ratios. In eleven of the thirty analyses, people-per-room does have a significant direct path to pathology measures. However, seven of the paths (the largest ones) are for the "care of children" pathology indicators, many of which (as we show below) are indicators of crowding experience rather than pathology. When these are removed from consideration, the effect of people-per-room is either not significant or modest (Betas of .12 or less). Therefore, it is not the presence of a direct effect of people-per-room that is causing the ratios to vary. Rather, it is the magnitude of the effects of the experiential variables that affect the ratios, and this variation is created by the association of the experiential indices with poor mental health. Thus, bias in the experiential measures makes substantive interpretation of the effects of crowding on pathology meaningless when multiple regression is used.[2]

The measurement problems unfortunately do not stop here. While people-per-room is a commonly used measure of crowding, it has basic conceptual and methodological defects. Conceptually, it means that all members of the household require the same number of rooms. That is, four persons in a four-room household are as crowded as eight people in an eight-room dwelling, and four unrelated adults need the same number of rooms as a couple with two small children. This is untenable on the face of it. Small children do not need the same number of rooms as adults, and a married couple does not have need of the same number of rooms as two unrelated adults. Further, room needs do not increase proportionally to the people gained. As a case in point, a three-room household may meet the space needs of a married couple with no children. The addition of four children is not likely to increase the space needs to nine rooms (the number of rooms needed to keep people-per-room constant). Because household composition influences space demands, people-per-room is limited as a measure of space demands.

Ratio variables (such as people-per-room) create methodological pitfalls in interpreting regression analyses (Fuguitt and Lieberson, 1974; Schuessler, 1973). Gove and his collaborators indicate that people-per-room has independent effects on selected mental health measures above and beyond what is explained by the number of people (including number of children) and the number of rooms, suggesting that the three variables measure somewhat different things. Curiously, after demonstrating that people-per-room is highly correlated with number of people in the household (a variable for which it is reasonable to assume a correlation with many of the same dependent variables), the authors do not control for number of people (or number of children) in their analysis. Perhaps the findings would have been very different had they done so.

---

[2] We would have preferred to compare the two models directly, using LISREL (Jöreskog and Sörbom, 1978) rather than multiple regression, but the authors refused to make the correlations matrix available to us. The indirect comparisons are, however, sufficient to challenge the adequacy of the measures used to tap crowding experience.

Not incidentally, the number of people in the household has conceptual and analytical implications for the lack of privacy and demands, the two other independent variables. As the number of people increases arithmetically, the complexity of interaction increases as an exponential function. Hence, the degree to which number of people is related to the experiential variables is an important consideration. Unfortunately, the analysis is presented in a way that does not permit us to evaluate the relations between the experiential variables and the components of people-per-room. How much variation in the experiential variables does number-of-people explain and how much variance does people-per-room explain? The omission of these variables from the tables render conclusions about the effects of the independent variables questionable at best. It is a puzzle why the investigators did not use less problematic measures such as rooms deficit (Booth, 1976:24–32), where crowding is derived from the average space needs of different types of households. The authors clearly had the data to do so.

One final measurement problem to be noted is that several dependent variables, those having to do with the care of children, are not dependent variables at all. They simply tap another dimension of crowding experience. One item has to do with whether children have a place to study (clearly a function of space) and another with whether children have difficulty getting away from others (related to both space and people). It is not surprising that the independent variables show substantial relationships with these items. It is noteworthy that the crowding variables have a negligible effect on the child care items having no spatial elements (physically punish child and supportive of child). Coupled with the failure to control for number of children in this analysis, it is indeed questionable if crowding can be viewed as an important variable affecting the care and behavior of children.

This leads us to another major problem, the deficiencies in interpretation. The investigators find a general pattern of low positive relationships between crowding and pathology, concluding that the adverse results are important consequences of crowding. They contend that the amount of variance explained by crowding is comparable to the size of effects found in other social science research using individual level data. We disagree. The mean total variance explained by the crowding variables for the 30 dependent variables shown is .042%. Given the questionable nature of the experiential variables, it is important to estimate the variance explained by people-per-room alone. Though not given in the report, we judge the mean variance explained by people-per-room to be approximately one-third that explained by all of the crowding variables, or .014%. This may be charitable since the average correlation between people-per-room and the dependent variables is .128, while for felt demands it is .174, and for lack of privacy it is .151. Explained variance of slightly more than 1% is very comparable to the amount of variance explained by crowding in the more than 30 health, family, and social variables explored in the Toronto study (Booth, 1976) where the mean explained variance is .023% for men and .020% for women.

Because means are sometimes deceptive, we include a tabulation (Table 1) of the explained variance broken down by percent for the dependent variables in the two studies. It is evident that in the Chicago study the combined measures explain just slightly more variance (approximately 2%) than the crowding measures in the Toronto study. Given the dubious value of the experiential variables, a comparison of the effects of people-per-room in the Chicago study with the variance explained by the crowding scales used in the Toronto study is in order. In this instance, people-per-room explains slightly less variance than the scales in the Toronto study. Why, then, the completely different interpretation of the results?

The fundamental question is: How large does an effect have to be before it may be regarded as important? Both of the other field investigations mentioned earlier (Toronto and Hong Kong) revealed slightly more adverse consequences than would be expected by chance. The large proportion of statistically significant relations found by Gove et al. (1979) may be accounted for in part by the size of the sample, which is three times the size of the one in the Toronto study (Booth, 1976). The larger Chicago sample is clearly more sensitive to detecting small effects.

How important are a few points difference on a list of psychiatric symptoms or alienation scale, or a few percentage points difference on

Table 1. Percentage of Variance Explained in Dependent Variables by the Chicago and Toronto Studies

	1–2 Percent	3–4 Percent	5–7 Percent	8+ Percent	Number of Variables
Chicago Study					
Number of variables for experential and people-per-room crowding variables	9	11	8	2	30
Number of variables for people-per-room variable	28	—	2	—	30
Toronto Study					
Number of variables for combined crowding measures					
Males	19	8	4	—	31
Females	22	7	3	—	32

an item where the respondent judges his health or the closeness of his/her spouse? As Gove and his collaborators do not present us with the unstandardized regression coefficients, or even a matrix from which they may be reproduced, it is not possible to estimate the exact effect of a change of one point on a privacy scale or of a room on the people-per-room index. The diminutive variance explained would suggest that the effects are small and probably similar to those found in other field studies. In terms of the overall well-being of the individual, these are insignificant and far removed from the impact of such things as losing a job, dropping out of school, becoming disabled, or being the victim of a crime. The type of effects found in the Chicago study are small influences in a world in which every human is subject to numerous adverse and positive influences each day—stresses which most individuals are fully equipped to cope with as part of everyday life.

In our view, the Gove et al. (1979) results are not unlike those reported from comparable studies. However, the deficiencies in measurement and interpretation are compounded by lesser, though significant, problems in sampling and analysis. The Chicago sample is not a representative probability sample. Tracts were selected on the basis of their chance of yielding crowded households, blacks and certain socioeconomic levels. According to the investigators this was done to reduce the dependence of the crowding measures on the background variables and to maximize the range of variation in the crowding measure. Such manipulations of the sample may have little effect on the measures of central tendency, as is shown for their sample, but they do affect measures of dispersion and the correlations among the measures. To use beta coefficients and contributions to explained variance as population parameter estimates, when the sampling design tampers with the standard deviations and the correlations among the measures, is a flaw in the analysis. This is a particularly serious flaw when the authors proceed to conclude: (1) that the crowding measures have substantial effects independent of the control variables; and (2) that the crowding measures often explain more variance in the dependent measures than do the controls. Such conclusions may be the result of the sampling design, and any substantive interpretations drawn from them are likely to be distorted (Blalock, 1967).

The report is also marred by crucial omissions. Reliability figures for the two experiential scales are not given. The investigators present evidence to indicate that lack of privacy is significantly related to race and that felt demands is associated with the sex of respondent (Gove et al., 1979:65). The data suggest there may be important interaction effects. These are never explored. Typically, researchers include in the presentation of their findings a zero-order correlation matrix of the relations between key variables. This allows the reader to examine the data for alternative explanations and to check the investigators' conclusions. Means and standard deviations are usually presented so that the reader can examine the distributional properties of the variables and decide whether they are in sufficient conformity to the requirements of the statistical procedures used. None of this is available to the reader of the article by Gove and his associates.

On the basis of our review of the Chicago crowding study, we suggest that:

1. the lack of privacy and excessive demands from others may be signs of psychopathology as much as measures of crowding;
2. people-per-room as a measure is not uniformly suitable for different types of households and should be used only when there is some control for the number of people in the households;
3. some of the dependent variables which

were used contain elements of the independent variable;

4. the sampling frame may distort the standardized regression coefficients, thus leading to erroneous conclusions;
5. significant amounts of crucial analyses are omitted from the presentation; and
6. the findings are similar to those of other field studies showing crowding to have negligible effects on pathology.

The examination of the findings of Gove and his collaborators (1979), in the light of the problems in their measures, interpretation, sample and analysis, leads to the conclusion that household crowding has small effects on the health and well-being of families in some cases. Rather than showing large effects, rivaling the impact of more traditional demographic variables, our interpretation of the findings would suggest they are remarkably similar to those of previous research.[3] The findings support, not reject, the contention that household crowding is a variable of minimal importance in explaining pathology, at least in modern industrial society. On the basis of findings to date, pathology has little to do with crowding.

IN PURSUIT OF PRECONCEPTIONS: A REPLY TO THE CLAIM OF BOOTH AND HIS COLLEAGUES THAT HOUSEHOLD CROWDING IS NOT AN IMPORTANT VARIABLE*

(REPLY TO BOOTH, JOHNSON, AND EDWARDS)

A casual reading of Booth et al.'s (1980) comments would seem to indicate that there are serious problems with the analysis and conclusions in the study by Gove et al. (1979) on the effects of household crowding. A careful reading suggests that on some points Booth et al. have made very serious mistakes, and on other points they have raised serious issues that need to be addressed. We are happy to have the opportunity to demonstrate that the issues they raise do not, in fact, impose serious problems with our analysis or conclusions.

(1) Booth et al. (1980) state that lack of pri-

---

[3] We had similar expectations concerning the pathological effects of crowding at the initiation of the Toronto project. Contrary to our beliefs, we found that crowding effects simply were not there in the magnitude we anticipated. In a like vein, many of the reviewers of the almost two dozen reports on the Toronto project responded, "I see the results, but I still don't believe them." A lesson in the sociology of knowledge obviously could be, and needs to be, drawn here.

* Address all correspondence to: Walter R. Gove; Department of Sociology; Vanderbilt University; Nashville, TN 37235.

vacy and overstimulation by social demands "should be conceptually and analytically distinct from the measures of social pathology. Yet no evidence of such a distinction is reported by Gove et al." It is true that we made no attempt to justify the conceptual and analytic distinction between overstimulation by social demands and lack of privacy and our various measures of mental health, poor social relations, poor physical health and poor child care because we assumed that at the conceptual level the distinction between these concepts is obvious. However, it is clear from Booth et al.'s discussion that what they are really concerned with is that our operational definitions of lack of privacy and overload of social demands overlap with some of our dependent measures, particularly mental health, that this seriously muddles our analysis and may have led us to an erroneous conclusion. The latter issue we see as a serious one, and we will devote the latter part of our rejoinder to demonstrating that a seemingly plausible problem is, in fact, not problematic.

(2) Booth et al. (1980) present what they take to be our model, state that it is misspecified, and then propose a path model which they believe is the correct model. The claim that the model presented in their Figure 1 is our model is a misrepresentation of our position. We very clearly state (Gove et al., 1979:62) that this model is oversimplified and is only a very general model of the way crowding affects pathologies. Furthermore, we strongly imply that the pattern of relationships among the three indicators of crowding will vary across pathologies. Perhaps more to the point, we did not present and/nor attempt to test a path model of crowding at all. Instead, our paper is an attempt to answer two very simple, related questions: First, does crowding explain a significant amount of variance in indicators of social pathology over and above that explained by traditional demographic indicators? Second, do the crowding variables generally explain as much variance in indicators of pathology as do the demographic variables, which are generally taken as important predictors in sociology? These questions are not amenable to the kind of causal analysis which Booth et al. suggest.

If we were interested in testing a causal model, we would not proceed in the way Booth et al. appear ready to do. In their path model, they hypothesized that poor mental health leads to lack of privacy and an excess of demands. We assume that they are not concerned with objective levels of privacy and demands, but with the subjective experience. At the moment we will deal with the usefulness of their proposed path model. As Duncan (1975:168) notes, "causal models in sociology are likely to be seriously misspecified," and, as his book demonstrates, the utility of path models is limited to a very narrow range of phenomena (also see Leik 1979:602).[1] One could devote an entire paper to the problems with Booth et al.'s model and their attempt to draw conclusions from it but simply pointing out their basic flaws should be sufficient.

First, to be properly specified, their model must include the control variables of sex, race, marital status, education, age, and family income which were used in the analysis. The exclusion of these variables means they have a misspecified model.

Second, the various pathological domains discussed in our paper—mental health, social relations in the home, physical health and child care—are all related domains. Mental health affects social relationships, physical health and child care. Similarly, social relations, physical health and disruptive children all affect mental health. Comparable relationships occur with the other domains. At the same time, the various components of the domains are analytically distinct and empirically distinguishable (e.g., for our mental health measures see below; for social relationships, see Brocki 1979). In short, for a properly specified model, the need, at least initially, is to include a large number of measures of mental health, social relationships, physical health and child care. In constructing the initial path model within each domain, each dependent variable should be presented as involved in a complex network of causal relations with each of the others. Furthermore, in the initial analysis, each of the variables within a domain should be treated as though it were related to all of the other variables in all of the other domains. Obviously, as a practical matter, this is not a problem amenable to path analysis, and any attempt to analyze this data by path analysis would be meaningless.

---

[1] Leik (1979:602) states:

> If there is only one approach to theory, in the sense of the kind and shape of acceptable relationships (asymmetric, linear), then we do not even ask many potentially useful questions. All rates of change are constant, all variables are capable of exceeding any specifiable bounds, all effects are assumed to be from variable to variable, rather than to rates of change, to thresholds or ceilings, or to other parameters of more basic equations. In short, the only questions asked are whether more variables should be added and in what order they should appear. There is not much creativity in such an enterprise.

However, even if we go along with Booth et al. (1980), their analyses do not support the conclusion that our subjective scales are biased due to an underlying relationship with the mental health of the respondent.[2] Booth et al. present a mathematical analysis which suggests that if no bias were present in our measures of subjective crowding, then the ratio of the regression coefficient between objective crowding and pathology (controlling only demographic variables) to the regression coefficient between subjective crowding and pathology (controlling only demographic variables) should be constant across pathologies. According to Booth and his colleagues, if the value of this ratio changes across our pathologies, and if the ratio declines in value for indicators which are highly related to mental health and increases for variables which have no conceivable relationship to mental health, then there is evidence of bias.

Which variables should we look to as measures of mental health of the respondents? Booth et al. (1980), in the third paragraph of their comment, mention several, all among the variables we specifically indicate in our article as measures of mental health: ". . . irritation, alienation, a lack of positive affect, low self-esteem, and unhappiness. . . ." However, when they summarize their analysis of the ratios, their list of variables having the lowest ratios (those variables which, if Booth et al. are correct, should be indicators of mental health), contains none of the variables they suggested as measures of mental health possibly affected by bias. The variables with the lowest ratios are "involved in arguments; not enough sleep; catch a bug from others; not cared for by others; psychiatric symptoms; nervous breakdown; and, get along with others—all of them, variables closely tied to the conceptualization of poor mental health." Only two of these variables were among the group of mental health variables in our article; the others involve health and social relations in the home. As we indicated above, these other variables may have some relation to mental health, but it is hard to support the claim that they are "closely tied to the *conceptualization* of poor mental health" (emphasis added). Two of these variables seem very far from any definitional relationship with mental health: "not cared for by others," (The wording of the actual question was: "When you are *really* sick, is there someone to help take care of you?") and "catch a bug from others" (The actual wording of the question was: "If someone else at home is sick with the bug, do you often seem to catch it?"). How these items are closely tied to the "conceptualization of poor mental health" escapes us, and the idea is not defended or explained by Booth et al., simply asserted.

If one looked only at the lowest ratios presented by Booth and his colleagues, then one might think that there was some substance to the claim that our subjective scales are biased. However, Booth et al. also present the variables with the highest ratios. These are "positive marital relations; child care [i.e., all the child care items]; alienation; mental health balance; overall health; and physical violence—*variables that cannot be readily viewed as indicators of poor mental health*" (emphasis added). Booth et al. claim without additional comment that indicators in this list, which contains two of our mental health scales (mental health balance and alienation), and one of the scales which they suggested in the third paragraph of their comment to be an indicator of mental health (alienation), "cannot be readily viewed as indicators of poor mental health."

Given their claims about variables with low ratios, their claims about variables with high ratios seem very questionable. It is difficult to understand how Booth et al. can claim that "getting along with others" is an indicator of mental health, yet positive marital relations is inconceivable as a measure of mental health, as though positive marital relations does not involve getting along with anyone. If having arguments is so closely tied to the "conceptualization of poor mental health" (Booth et al., 1980), then why is becoming involved in physical violence (an escalated argument) so obviously unrelated to mental health? Tessler and Mechanic (1978) demonstrate that physical health and mental health are very highly intercorrelated, yet Booth et al. suggest, with no evidence and no rationale, that physical health is among the variables least related to mental health.

There does not appear to be any pattern in these variables which indicates that our subjective scales are biased because of mental health. There seems to be quite an adequate number of indicators of mental health among variables with high ratios, and among those with low ratios to prevent us from discovering the trend suggested by Booth et al. as indicative of bias. This is particularly evident when one calculates the suggested ratios for all the variables in our article, and arranges them from high to low as in Table 1.

[2, 3] We would emphasize that in another factor analysis, where we looked only at items measuring experiences in direct reaction to crowding, the experience of an excess of social demands and lack of privacy emerged as two very distinct and strong factors.

Table 1. Ratios Suggested by Booth et al. (1980) as Demonstrating Bias in the Subjective Scales of Crowding, Arranged in Descending Order

	Ratios*	Mental Health Variables $\bar{X}$ = .582	Social Relations in the Home $\bar{X}$ =.577	Physical Health $\bar{X}$ = .448	Care of Children $\bar{X}$ = 1.79	Items Suggested by Booth et al. $\bar{X}$ = .651
Supportive of child	3.55				C	
Positive affect	(−)2.90**	M**				B**
Know parents of playmates	2.68				C	
Know child's playmates	2.34				C	
Child can get away from others	1.84				C	
Child has place to study	1.32				C	
Physically punish child	1.27				C	
Alienation	1.03	M				B
Involved in physical violence	.966		S			
Positive marital relations	.920		S			
Overall health	.855			H		
Mental health balance	.766	M				
Relief when children out of home	.700				C	
Marital relations balance	.630		S			
Children are a hassle	.626				C	
Self esteem	.609	M				B
Must do chores (when sick)	.545			H		
Happiness	.529	M				B
Cannot get good rest	.506			H		
Feel close to spouse	.467		S			
Negative marital relations	.445		S			
Manifest irritation	.434	M				B
Nervous breakdown	.406	M				
Psychiatric symptoms	.301	M				
Get along with others	.296		S			
Not cared for by others (when sick)	.296			H		
Catch 'bug' from others	.278			H		
Not enough sleep	.208			H		
Get along with children	−.135**		S**			
Involved in arguments	.018		S			

* It is unclear how Booth et al. (1980) calculated their "average ratios." The ratios in this table were calculated by obtaining the ratios associated with the privacy scale and the demands scale, and then calculating the mean of these two ratios.

** These items were not included by Booth et al. (1980) because of negative sign. These ratios are not included in the calculation of the means at the top of the Table. Booth et al. (1980) mention 3 ratios with negative signs, while we appear to have only 2. This is because for one item there are two negative signs while for the other there is one.

The items which we would suggest are the best indicators of mental health are those which we included in our original Table 3, entitled "Overcrowding and Mental Health" (Gove et al., 1979:71). Ratios for these variables are widely scattered up and down the range of the ratio. The mean value of the ratio for all the mental health items is .582, clearly not the lowest for all the four groups of variables. Child care is highest, with a mean of 1.79, followed by mental health at .582, social relations in the home at .577, and physical health at .448. The mental health items suggested by Booth et al. as items possibly confounded with our subjective scale have a mean ratio of 1.10 if one includes positive affect (a scale which Booth et al. (1980) eliminate from consideration because the negative sign for its ratio makes it "ambiguous") and .651 if positive affect is excluded. This ratio of .651 is about three times higher than the low group of variables (mean .22) claimed by Booth et al. to be "closely tied to the conceptualization of poor mental health." We are mystified why Booth et al. ignore these more relevant comparisons and try to make us believe that the variables with low ratios are measures of mental health and those with high ratios are not.

There does appear to be variation in the ratio across our indicators of pathology, but this ratio does not vary in the way Booth et al.

claim is indicative of mental health bias. What Booth et al. do not make clear is the fact that this ratio will vary if the pattern of relationships between objective crowding and pathology and subjective crowding and pathology changes from one indicator to the other. This is precisely what would happen if the effect of the subjective scale relative to the effect of objective crowding changed from one variable to the next, and/or the impact of controlling for the demographic variables on the relationship between subjective crowding and pathology relative to the impact of controlling for demographics on the relationship between objective crowding and pathology changed from one indicator of pathology to the next. This is what one would expect unless each of the indicators of pathology was related to the subjective and objective measures in exactly the same way—a situation which we specifically suggested in our original (Gove et al., 1979:62) article was likely *not* to be the case.

(3) Booth et al. (1980, fn. 2) indicate that they asked us to make some of our data available to them so that they could check on the accuracy of our analysis and conclusions, and that we refused to provide them with the data. We would like to indicate why we chose not to give them the data they requested. First, we are presently involved in more thorough analyses of our crowding data (Gove et al., forthcoming, 1981) and did not want to make our data publicly available until the more complete analysis was published. Second, and more serious, we had questions about the way Booth intended to use our data. As is indicated in Gove and Hughes (1980) the work of Booth and his collaborators is replete with numerous conceptual and methodological flaws, and we were concerned that they would unknowingly misuse our data and produce an analysis that was substantially flawed. For example, in a number of articles Booth and his colleagues indicate that the characteristics of their sample "do not limit the generalizability of findings to urban adult family members" (Booth 1977:647; see also Edwards and Booth 1976:75; and Booth and Welch 1978:25, for a virtually identical claim). Given the very atypical nature of their sample, this seems like a very strong statement. In each case, it was justified, however, by presenting the demographic characteristics of Toronto and comparing them to the demographic characteristics of a sample of 4,889 respondents randomly drawn from the 17,128 households screened, and *not* to the characteristics of the 862 households *interviewed* and actually included in the sample (see Booth, 1976:38–9). The characteristics of the households screened, however, were very different from the subset selected for interviewing. To give only one example, in the screened sample, 69% of the households had intact families, and in the interviewed households, all the families were intact. It is, thus, impossible to empirically support the claim that the characteristics of the sample "do not limit the general applicability of the findings to urban adult families." This misrepresentation of their data, combined with the fact that they wanted to use our data to test their inappropriate path model, and the fact that they present contradictory evidence in regard to ratios discussed above as supporting their position would seem to justify our caution.

(4) Citing Fuguitt and Lieberson (1974) and Schuessler (1973), Booth et al. indicated that the use of the ratio variable, persons-per-room "create[s] methodological pitfalls." However, as is shown by Long (1980) and Kasarda and Nolan (1979), the use of a ratio variable is nonproblematic when there is little measurement error. The number of persons in a household and the number of rooms in the household (particularly when there are detailed instructions on how to count rooms) should contain little measurement error, particularly when compared to most variables used by sociologists. In short, the use of this particular ratio variable is appropriate.

(5) Although we are studying crowding, and Booth et al. (1980) acknowledge that we demonstrated that our objective measure of crowding, persons-per-room, does measure crowding and not something else, they indicate we should have added to our control variables the number of persons. They give no theoretical reasons for adding the number of persons to our analysis, and the number of persons is not a measure of crowding. Furthermore, when Booth and Edwards (1976) used persons-per-room, they themselves did not control on the number of persons. As the number of persons comprises the numerator of our measure of crowding, the empirical effect on purely mathematical grounds has to be to decrease substantially the apparent effect of crowding, and is, in fact, highly collinear with crowding (r – .801)—a situation which would cause severe methodological problems. In the absence of any theoretical reason for including the number of persons in the analysis, we are totally mystified by their suggestion.

(6) Booth et al. (1980) suggest that we use the rooms-deficient measure developed by Booth (1976). However, that measure is seriously flawed as a measure of crowding. What the measure establishes is the typical number of rooms for households containing different combinations of types and numbers of house-

hold members. If the number of rooms is fewer than is typical for a particular combination of types of household members, then the household is "crowded," and if it has more rooms than the average for that "household type" then the household is "uncrowded." What Booth never considers is that for some combinations of household members (e.g., poor, multigenerational households), the household with the average number of rooms may be very crowded while for other household combinations (e.g., husband and wife only) the average number of rooms may, in most cases, reflect low levels of crowding. To take the extreme case, a person who lives alone in two rooms might very well, by their definition, be socially crowded. Finally, we would ask why, if their measure is so good, they did not use it as an independent variable in their study?

(7) The final measurement problem Booth et al. (1980) note is that we have several dependent measures that are not dependent variables at all. Booth et al. mention two: "no place for a child to study" and "no place at home where the child can get away from others." Since those are the only questions of this nature, we obviously have only two questions, not several. Furthermore, as they note, these questions "tap [a] dimension of [the] crowding experience." As we are studying the crowding experience, we are puzzled that Booth et al. would find these questions inappropriate. We would note that Booth and Johnson (1975) found children in crowded households to be one year behind in school, and we would suggest that one of the major reasons for this finding, which we view as important, is tapped by the two questions asked.

(8) Booth et al. discuss at considerable length the amount of variance explained by our crowding variables and they indicated that the amount borders on the trivial. First, we would note that we explain twice as much variance as that explained by Booth et al. Second, the amount of variance uniquely explained by our three crowding variables is 4.2%, and the amount of variance uniquely explained by the combined effects of our six control variables (sex, race, marital status, education, age, and family income) is 4.1%. Thus, the percent variance explained may seem small to Booth et al. but, compared to the traditional variables used by sociologists, it is substantial. Furthermore, the total variance explained by the crowding variables (including collinear variance) is 5.7%, not 4.2% as Booth and his colleagues assert.

In total, for our 30 variables we explain an average of 9.8% of the variance. We go to considerable length to demonstrate that, for survey data of this type, this is about the amount of variance one would expect to explain. We made the point that this fact is not always recognized. To demonstrate our point once again, let us note three very diverse studies. Chiricos and Waldo (1975) investigated the determinants of criminal sentencing and looked at the effects of SES, age, race, urbanization, confinement in a juvenile institution, prior arrests and prior convictions; they found that out of 11 analyses, these variables, on the average, expalined 8.9% of the variance in sentence length. Wolinsky (1978) studied 24 indicators of health facility utilization and used 29 predicting variables, including restricted days, bed disability days, lost days, subjective health limited mobility, limited activity, total health conditions total chronic conditions and total chronic conditions limiting activity or mobility. On the average he explained 10.4% of the variance in health utilization. Warheit et al. (1976) looked at marital status, age, SES, sex, race, marital history plus some interaction terms and explained 10.7% of the respondents' mental health scores. In summary, with individual data one should not anticipate explaining much variance.

(9) Booth et al. (1980) assert that we selected census tracks on their "chance of yielding crowded households, blacks and certain socioeconomic levels." This statement misrepresented what we did. We selected tracks to get a representative range of crowding, SES and the proportion of blacks residing in Chicago, while at the same time attempting to minimize the collinearity between crowding and SES. (In doing our selection there was a slight tendency to overselect tracks with both high and low SES.) Booth et al. state that our sampling design affected our measures of dispersions and the correlation among the measures. They assert that we have committed a "particularly serious flaw when [we] proceed to conclude . . . that our crowding measures have substantial [independent] effects. . . ." As is clearly indicated in Table 1 of our article (Gove et al., 1979:63), the variation in our control variables appears to be similar to the variation on the same variables as Chicago. These data will be presented in more detail in Gove et al. (1981). If there is any deviation, it is that we have more variation in the sample on our measures of SES than occurs in Chicago, and thus our sample is slightly weighted toward finding strong effects of SES as compared to crowding. Thus the issue raised by Booth et al. is not a serious one. Furthermore, it is certainly appropriate for us to draw conclusions regarding the census tracks from which we draw representative samples, and (as noted) these tracks are selected such as to be fairly

characteristic of Chicago (except that there should be less collinearity between SES and crowding in our sample than in Chicago).

Booth (1976) draws the same type of conclusions we drew, differing only in that he concluded crowding had very little effect. As Booth (1976) notes, and Gove and Hughes (1980) emphasize, he drew his sample from very atypical and very crowded census tracks. Furthermore, Booth (1976) did not randomly sample households residing in those census tracks (as we did) but screened households, obtaining interviews in only 3.3% of the households screened. Thus, Booth (1976) is not only not in a position to draw any conclusions regarding crowding in Toronto, but he is also in no position to draw conclusions regarding the census tracks he sampled. If Booth et al. (1980) think our sampling design makes it difficult to draw conclusions, they should apply the criteria they raise regarding our study to the Toronto study. If they do, they will find by their own criteria the sample design in the Toronto study is so flawed that they have an insurmountable problem and have no basis from which to draw any general conclusion regarding the effect of crowding.

(10) Booth et al. also criticize us for omitting data and not considering certain interactions in more detail. We would note two things: First, the paper originally submitted was twice as long as the paper published and thus some omissions were not by our choice. Second, much more detailed analyses will be presented in Gove et al. (1981).

(11) To us the most serious issue raised by Booth et al. (1980) is whether our operational indicators of a lack of privacy and overload of social demands are empirically as well as analytically distinct from our measures of mental health. In their path model Booth et al. treat mental health as a single variable which clearly suggests that they are willing to treat mental health as an unidimensional concept. However, even before Bradburn's (1969) excellent book on psychological well-being, it had become clear that mental health involves a variety of analytically and empirically distinct dimensions. As this is the case, and as we used a variety of indicators of mental health, the question really is whether our measures of the experience of crowding (lack of privacy and social demands) are measuring the same thing that our various indicators of mental health are measuring. In the section below we present a factor analysis which indicates that psychiatric symptoms, positive affect, self-esteem, manifest irritation and the subjective experience of crowding, as we have measured them, are empirically distinct. We then briefly discuss our measures of alienation, happiness and the mental health balance scale.

The factor analysis is presented in Table 2. It clearly demonstrates that our measures of psychiatric symptoms, the experience of crowding,[3] self-esteem, manifest irritation, and positive affect (1) are distinct factors and (2) the items in each scale tend to load only on one factor. This is particularly important with regard to the measures of the experience of crowding, for it clearly demonstrates that the items measuring mental health and those measuring experience of crowding are empirically as well as analytically distinct. In short, the problem which Booth et al. suggested underlay our analysis, namely, that our measures of the experience of crowding and mental health were empirically indistinguishable, is simply not a problem. We would note that these factors all scale at least reasonably well (the alpha reliability coefficient with psychiatric symptoms is .85, with experience of crowding it is .73, with self-esteem it is .72, with manifest irritation it is .68, and with positive affect it is .66).

Regarding our other measures of mental health, our measure of alienation is actually a composite of three subscales (political powerlessness, normlessness and belonginglessness), and its overall alpha reliability coefficient, which is .58, is actually lower than the alpha reliability of some of its subscales. As a consequence, the alienation items do not emerge clearly as a factor. Nevertheless, when it is entered into the factor analysis, it emerges as the sixth factor with an eigen-value of 1.16. Furthermore, the alienation items are unrelated to the experience of crowding (only one item achieves a factor loading of over .1 on the experience of crowding factor, and three of the items are negatively related). When nervous breakdown is entered into the analysis as a single item, it obviously will not emerge as a separate factor; instead, it has a moderate loading on the psychiatric symptoms factor (.37), and is unrelated to the other factors. However, a nervous breakdown is obviously a powerful experience and warrants being included in an investigation of mental health. As Campbell et al.'s (1976) discussion of happiness demonstrates, happiness is clearly an important and analytically distinct concept. It has a very modest negative loading on the positive affect factor, but by and large it appears to be largely unrelated to any of the factors presented in Table 2. The mental health balance scale is a combination of the psychiatric symptom and positive affect scales and is thus inappropriate for inclusion in our factor analysis. The mental health balance scale is

Table 2. Varimax Factor Rotation of the Individual Items in the Four Major Mental Health Scales and the Subjective Experience of Crowding Scales (Lack of Privacy and Social Demands)

		Factor 1	Factor 2	Factor 3	Factor 4	Factor 5

Eigen-values		6.22	2.44	1.55	1.89	1.08

useful not only because it probably is the best summary measure of mental health (e.g., see Bradburn, 1969; Cherlin and Reeder, 1975). We would emphasize, however, that Bradburn and, particularly, Cherlin and Reeder see the individual components of mental health as worth more attention than any summary measure.

In conclusion, the items involved in the factor analysis presented in Table 1, as well as the items discussed only in writing, provide a very clear demonstration that the measures of the experience of crowding are not empirically confounded with our measures of mental health. This is not to say that the experience of crowding is not related to one's mental health; in fact, our whole analysis is based on the assumption (and demonstration) that such a relationship exists. What our analysis does indicate is that not only are the concepts analytically distinct, but that they have been measured in such a manner that the operational definitions are also empirically distinct.

To summarize, we have carefully considered all of the issues raised by Booth et al. and conclude that none of the issues raised by Booth et al. regarding the validity of our study withstands careful scrutiny. We reassert that our study strongly suggests that crowding does often have substantial effects, and it is time to turn away from the question, "Does crowding ever have effects?" and turn toward questioning the conditions which maximize or minimize the effects of crowding.

ITEMS

■ CHRISTOPHER JENCKS (Heredity, Environment, and Public Policy Reconsidered) is Professor, Department of Sociology and Center for Urban Affairs, Northwestern University. His current research centers on the social indicators of unselfishness as well as on trade-offs between earnings and other job characteristics. His latest book (from Basic Books, 1979, and written with 11 coauthors) is *Who Gets Ahead?*

■ JAMES N. BARON (Bringing the Firms Back In) is a Ph.D. candidate in the Department of Sociology at the University of California–Santa Barbara. WILLIAM T. BIELBY is Assistant Professor of Sociology, also at the University of California–Santa Barbara. The two are also affiliated with the Social Process Research Institute at UCSB. They are collaborating on a three-year study of economic segmentation, technology, and work organization being funded by the National Science Foundation.

■ RICHARD A. BERK (Crime and Poverty), Professor, Department of Sociology, University of California–Santa Barbara, is busy on three research projects: (1) evaluation of California Senate Bill 224; (2) a monograph reporting evaluation of impact of water-conservation programs in California; and (3) how to improve ways of monitoring the performance of the criminal justice system. His book (with Lenihan and Rossi, and from which this article is drawn), *Money, Work, and Crime*, is forthcoming from Academic Press. KENNETH J. LENIHAN is Associate Professor at John Jay College, the CUNY, and has worked for a decade in the area of criminal justice research. His most recent monograph, "Opening the Second Door," was published by the U.S. Department of Labor Employment and Training Administration. PETER H. ROSSI is Professor, Department of Sociology; and Director, Social and Demographic Research Institute—both at the University of Massachusetts–Amherst. Crime seriousness, social experimentation, and estimating household damage from natural disasters are among his fields of research interest. His book, *Hand of Survey Research* (written with Wright and Anderson), will be published by Academic Press in 1981.

■ DAVID A. SNOW (Social Networks and Social Movements) is Assistant Professor, Department of Sociology, University of Texas, Austin. He is engaged in research dealing with movement recruitment and conversion, interactive processes in crowds, the systematization of qualified research techniques, and the social construction and implications of "accidents." LOUIS A. ZURCHER, JR., also at the University of Texas, Austin, is Professor, Graduate School of Social Work and Department of Sociology. His present research is in the areas of: self-concept and social change, the dramaturgical nature of emotion, and symbolic interactionism of scapegoating. His *Human Responses to Social Problems* (with Louis Schneider, Cookie White Stephan, and Sheldon Olson) is forthcoming from Irwin-Dorsey. SHELDON EKLAND-OLSON is Associate Professor, also in the Department of Sociology at the University of Texas, Austin. He is doing (1) a study of "coming home from prison" and (2) conceptual development of the importance of social networks for studies of deviance and social control.

■ JOHN HAGAN (Differential Sentencing of White-Collar Offenders) is Professor, Department of Sociology, University of Wisconsin–Madison. He has just completed a monograph, "The Organizational Domination of Criminal Law: A Study of Victim Involvement in the Criminal Justice System"; and is involved in a study of the sanctioning of stocks and securities violators in Toronto. ILENE H. NAGEL (BERNSTEIN) is Associate Professor, School of Law, Indiana University. During the Fall, 1980, she is a Visiting Fellow at the Institute of Criminology at Cambridge University and at the Netherlands Institute for Advanced Study in the Humanities and Social Sciences. She and John Hagan have a forthcoming book on prosecutorial and judicial discretion with emphasis on the differential impact caused by a variety of elements. CELESTA ALBONETTI is a graduate student at Indiana University. She is working on an analysis of the impact of structural effects on the frequency and type of organizational contacts among treatment programs for adjudicated juvenile delinquents. In addition, she wants to do further research, applying organizational concepts to the analysis of the criminalization process.

■ RONALD S. BURT (Testing a Structural Theory of Corporate Cooptation) is Assistant Professor, Department of Sociology and Survey Research Center, University of California–Berkeley. His chief interest is the general development of structural sociology. KENNETH J. CHRISTMAN is a Ph.D. candidate in the Department of Sociology and is also at UC–Berkeley. In addition to studying the sociology of organizations, he is pursuing research in social psychology and is completing a monograph on the social psychology of Emile Durkheim. HAROLD C. KILBURN, JR., is a Ph.D. candidate also, in the Department of Sociology, State University of New York–Albany. He is currently engaged in a comparative analysis of interorganizational networks.

■ GARY D. LA FREE is Assistant Professor, Department of Sociology, University of New Mexico. With Barbara Reskin, he is studying jury verdicts in rape cases. He is also researching official decision-making processes in felony cases.

■ MARCIA WHICKER TAYLOR (Comment on Scarr and Weinberg) is Assistant Professor, Department of Government and International Studies, University of South Carolina. She is developing several computer simulation models which examine the impact of government structure and policies upon the distribution of rewards and upon citizen preference maximization.

■ WALTER R. GOVE (Comment on Booth, Johnson, and Edwards) is Professor, Department of Sociology, Anthropology, Vanderbilt University. MICHAEL HUGHES, on leave from his Assistant Professorship at Virginia Polytechnic Institute and State University, is also at Vanderbilt through the Fall semester, 1980. He and Gove, under an NICHD grant, are looking even further at the effects of both "crowding" and "living alone" upon mental health and general well-being.

■ ALAN BOOTH (Comment on Gove and Hughes) is Professor, Department of Sociology, University of Nebraska–Lincoln. DAVID R. JOHNSON is also at Lincoln, University of Nebraska, as an Associate Professor of Sociology. JOHN N. EDWARDS is Professor, Department of Sociology, Virginia Polytechnic Institute and State University.

Introductory Sociology

Order and Change in Society
Third Edition

GERALD R. LESLIE, University of Florida; **RICHARD F. LARSON**, Clemson University; and **BENJAMIN L. GORMAN**, University of Florida. Designed for students in the general survey course, *Introductory Sociology* stresses the interrelations of social life, social processes, and social institutions. The text covers all the major substantive areas of contemporary sociology, and thoroughly integrates major theoretical models and research methods. Outlines, summaries, lists of important terms, annotated readings, questions, and projects are included. Clearly written, lavishly illustrated and handsomely designed, *Introductory Sociology* presents sound sociological principles in a manner both comprehensible and relevant.
1980 608 pp.; 200 photos, 50 figs. $17.95

The Social Condition of Humanity

An Introduction to Sociology

IRVING M. ZEITLIN, University of Toronto. This unique introduction to the sociological perspective acquaints the student with the classical foundations of sociological analysis. Informed throughout by sociological theory, the book employs classical conceptual tools to address basic questions concerning the human condition in all the major areas of sociological concern.

January 1981 450 pp. paper $8.95

The Study of Social Problems

Five Perspectives

Third Edition

EARL RUBINGTON, Northeastern University, and **MARTIN S. WEINBERG,** Indiana University. Designed for the social problems course, this text-reader offers a structured survey, examples, and criticisms of five major perspectives on social problems: Social Pathology, Social Disorganization, Value Conflict, Deviant Behavior, and Labeling. More than one third of the selections are new to this edition. Each group of readings is prefaced by an introductory essay and followed by discussion questions and an annotated bibliography.

February 1981 284 pp. paper $7.95

The Solution of Social Problems

Five Perspectives

Second Edition

MARTIN S. WEINBERG, EARL RUBINGTON, and **SUE KIEFER HAMMERSMITH,** Indiana University-Purdue University at Indianapolis. This reader traces the implications of the five perspectives presented in *The Study of Social Problems* and demonstrates the kinds of solutions each perspective prescribes. The editors' text has been completely rewritten for this edition, while the readings, which explore a wide range of social problems, including racism, sexism, poverty, and drug addiction, have been updated.

January 1981 220 pp. paper $7.95

Sentencing

Edited by **HYMAN GROSS,** Cambridge University, and **ANDREW VON HIRSCH,** Rutgers University. This collection of readings in the current literature addresses the issue of disparity in sentencing in the context both of the historical and philosophical background, and of the contemporary debates over the aims of sentencing, and the modalities and severity of punishment.

January 1981 426 pp. cloth $19.95 paper $9.95

City Lights

An Introduction to Urban Studies

E. BARBARA PHILLIPS and **RICHARD T. LeGATES,** both of San Francisco State University. This introduction to urban studies presents social science theory and research, artistic insights, and current policy issues in terms of competing perspectives, encouraging the reader to choose more intelligently among them. Highly readable, comprehensive, up to date in its scholarship, and attractively illustrated, the text features student-tested learning aids to stimulate questioning and theory-building.

Handbook of Organizational Design

Volume I: Adapting Organizations to their Environments

Volume II: Remodelling Organizations and their Environments

Edited by P.C. NYSTROM and W.H. STARBUCK

This important new reference work offers a comprehensive survey that summarizes and reinterprets current research and also indicates new directions in organizational theory. In drawing together contributions by prominent scholars from a broad range of fields, the editors emphasize the interdisciplinary nature of a field that encompasses research in different nations, industries, organizational forms, and a wide range of social science disciplines. The *Handbook of Organizational Design* will become an invaluable reference for those professionals and advanced students in business management and the social sciences, not only as a basis for planning but also for its contributions to future directions and development.

Volume I characterizes the effects of environments on organizations. Chapters in this volume analyze the adaptive capabilities of organizations such as planning, forecasting and innovation. Attention is also devoted to the effects of change, particularly changes in technology and in the legal and political systems.

Volume II focuses on the process of change within organizations, including control systems, interdepartmental relations and job design. Contributors discuss the effects, both planned and accidental, that organizations have upon their environments and analyze the relationship between organizations, governments, and society.

P.C. NYSTROM is an Associate Professor of Business Administration at the University of Wisconsin. W.H. STARBUCK is Helfaer Professor in the School of Business Administration at the University of Wisconsin.

Available March 1981

Volume I	588 pp.; 32 figs.	$29.95	$55.00 (set)
Volume II	540 pp.; 29 figs.	$29.95

Singular in the Social Sciences
because Dorsey is:

Dedicated to publishing carefully selected, top-quality books in Anthropology, History, Political Science, Public Administration, Psychology, Social Welfare, and Sociology.

Open to opportunities to publish and promote books in the Social Sciences that break new ground. Recognizing that creative thinking and writing are not exclusive to any one school of thought, Dorsey has been receptive to many different approaches and techniques.

Respected in the publishing industry for providing the works of many widely acclaimed authors to educational institutions in the United States, Canada, and abroad.

Specialized in the Social Science field, The Dorsey Press employs a solid editorial staff with extensive education and field training in their particular areas of expertise.

Experienced in textbook publishing, The Dorsey Press executes unusually effective methods of editing, designing, manufacturing, selling, and promoting college texts.

Yearly produces many new and revised texts in the same quality manner that has been used for over 20 years.

Community Development in America

edited by
James A. Christenson &
Jerry W. Robinson, Jr.

THIS is the first major assessment of the theory, research, and practice of community development (CD) in America.

The 25 contributors—all members of the Community Development Society—are experts from government, private enterprise, universities, extension service, and institutions.

They represent sociology, agricultural economics, planning, urban affairs, psychology, education, and social work.

The volume is designed to provide a state of the art of CD and information about CD. Key points include how it began, what it is today, problems CD faces, and future trends.

The three major themes of technical assistance, self-help and the conflict approach receive special emphasis.

What do community development professionals do? What are their individual traits, the functions they perform, the institutional setting in which they work, and their clientele?

Responding from a variety of perspectives, a cross section of CD workers share practical insights into their work.

Some major research is reviewed. A grounded theory framework demonstrates the integration of theory and practice in CD.

1980, 245 pp., ill., $8.50

Community Power Succession

Atlanta's Policy-Makers Revisited

by Floyd Hunter

Who really runs Atlanta? Hunter combines scholarly analysis, personal reminiscences, observation, and social prescription in his study of the power structure of one of America's most dynamic cities. "A fascinating and worthy successor to the now-classic *Community Power Structure*. This book shows how right Floyd Hunter was about Atlanta and how fruitful his research methods can be in talented hands." —G. William Domhoff, University of California, Santa Cruz

A Social Gathering of Penguins and Vikings

BREAKTIME: Living Without Work in a Nine-to-Five World
Bernard Lefkowitz
Breaktime examines the changing role of work in American society through the experiences of men and women of all ages, income levels, and life styles who have found alternatives to the regimen of the traditional workday. "Combines sensitivity to the social trends transforming our culture with a loving feeling for the individuals caught in these trends"—DANIEL YANKELOVICH.
0-14-005547-9 448 pp. $ 3.50

THE VIEW IN WINTER: Reflections on Old Age
Ronald Blythe
An unflinching, yet sensitive, inquiry into the experience of aging by the author of the now classic *Akenfield.* "A wise and beautiful book, splendid in its conception, lyrical in its prose . . . a classic in the literature of old age" —*The New York Times Book Review.*
0-14-005663-7 288 pp. $ 4.95

ENTROPY: A New World View
Jeremy Rifkin with Ted Howard
Derived from the Second Law of Thermodynamics, the Entropy Law explodes the myth of progress, stating that all energy inevitably flows from the orderly to the disorderly. This impeccably credentialed work shows how entropy is inextricably connected to the past, present, and future development of society. A Viking Book.
0-670-29717-8 324 pp. $10.95

ONE NATION DIVISIBLE: Class, Race, and Ethnicity in the United States Since 1938
Richard Polenberg (Cornell University)
Combining social, cultural, economic, and political perspectives, this lively study focuses on patterns of class, race, and ethnicity which have been of central importance in the lives of the American people.
0-14-021246-9 368 pp. $ 4.95

Announcing the February 1981 publication of . . .

THE WHISPERINGS WITHIN
David Barash
This highly accessible study draws upon the latest developments in sociobiology to explore the relationship between genetics and human behavior. "A delightful book, forcefully, effectively argued, with exceptionally good examples" —EDWARD O. WILSON, author of *On Human Nature.*

URBAN SOCIETY

An Ecological Approach, 2nd Ed.

Amos H. Hawley, *Universtiy of North Carolina*

Proceeding from the position that the form and content of man's collective life is a function of the efficiency of his means of transportation and communication, this text presents—in systematic form—the concepts, theories, and research findings on urban phenomena. The book explores the interrelations among the many kinds of urban knowledge, organizing them into an intelligible unity and revealing the relevance of this synthesis for an understanding of society as a whole. This revised edition brings all data up-to-date, with sections rewritten to incorporate new research findings.
(0 471 05753-3)   Jan. 1981   approx. 350 pp. paper

SOCIOLOGICAL THEORY

Classical Founders and Contemporary Perspectives

D. Paul Johnson, *University of South Florida*

Designed as a text in sociological theory, Johnson explains the key distinctions between the major underlying assumptions of the various theorists and schools of theory as he demonstrates their empirical and practical importance. Covers five classical pioneers of the field (Comte, Marx, Durkheim, Weber, and Simmel) and five contemporary schools of theory (symbolic interactionism, exchange theory, functionalism, conflict theory, and open systems theory). (0 471 02915-7)   1981   approx. 600 pp.

SOCIAL PSYCHOLOGY THROUGH SYMBOLIC INTERACTION, 2nd Ed.

Gregory P. Stone, *University of Minnesota,* & Harvey A. Farberman, *SUNY at Stony Brook*

A reader from the symbolic interactionist perspective for the social psychology course in sociology. Written by renowned authors who have made theoretical and substantive contributions to the perspective. The revised edition is designed for undergraduates, incorporating a pedagogical format, introductions and selections geared for that group. The new edition contains 41 reading selections—many of which are original.
(0 471 03029-5)   Jan. 1981   approx. 450 pp. paper

THE FAMILY AND SOCIAL CHANGE

Comparative Perspectives

Mark Hutter, *Glassboro State College*

An introduction to the study of the American Family from a crosscultural and historical perspective.
(0 471 08394-1)   Feb. 1981   approx. 500 pp.

UNDERSTANDING MARRIAGE AND THE FAMILY

James M. Henslin, *Southern Illinois University,* & James R. Hayes, *Southwest State University, Minnesota*

Look for this exciting cross-cultural reader for your courses in Marriage and the Family and Sociology of the Family.
(0 471 08606-1)   Feb. 1981   approx. 300 pp. paper

BLACK WOMEN IN THE LABOR FORCE
by Phyllis A. Wallace
with the assistance of Linda Datcher and Julianne Malveaux
Phyllis Wallace was a key figure in the A T & T case, the largest civil rights settlement ever established in the United States. In this new book, she analyzes the recent economic literature on black women workers and makes specific recommendations for improving their status in the labor market. The study's approach also provides insights on how to better utilize *all* women in the labor force.

LIVING WITH TECHNOLOGY:
Issues at Mid-Career
by Lotte Bailyn
in collaboration with Edgar H. Schein
An extensive foray into the diverse careers and midlife attitudes, aspirations, and prospects of more than 1,350 people who graduated from MIT in the 1950s. "This is the best analysis I have seen of a large-scale survey of people with technical educations."—Gene W. Dalton, Professor of Organizational Behavior, Brigham Young University.
$15.00

CONTROL AND IDEOLOGY IN ORGANIZATIONS
edited by Graeme Salaman and Kenneth Thompson
A general overview of theory and research on organizations, from the classic work of Weber, Durkheim, and Marx, to the most recent theoretical and empirical advances. "The book is very up-to-date; in fact, it is the best synthetic treatment of organizations that I know of that incorporates the range of recent thinking and research. The writing is uniformly quite good, and in a few places rises to a wonderful vividness."—Randall Collins, Professor of Sociology, University of Virginia.

CONTEMPORARY SOCIOLOGY
A Journal of Reviews

Norval D. Glenn, Editor
(Bi-monthly ISSN 0094-3061)

A journal of reviews, criticism, and debate designed to give new thrust and style to reviewing and intellectual exchange within the field.

Contemporary Sociology publishes reviews and critical discussions of recent works in sociology and in related disciplines which merit the attention of sociologists. Since all sociological publications cannot be reviewed, a selection is made to reflect important trends and issues in the field.

Recent issues have featured articles by:

• David B. Bills • Kenneth C. Boulding • Theodore E. Long • Alex Inkeles • Amos H. Hawley • Edward A. Tiryakian • Lewis A. Coser • William Julius Wilson • Alfred Kuhn • James Grier Miller • Anthony Giddens • Everett K. Wilson

Sociology and the Twilight of Man
Homocentrism and Discourse in Sociological Theory

By CHARLES C. LEMERT. "Lemert's analysis is fascinatingly original.... His challenge will be worth the attention of the professional sociologist." – *Library Journal*. "Lemert writes exceptionally well and clearly." – *Choice*.
0-8093-0975-0/$5.95 paper

THE AMERICAN SOCIOLOGIST

(James L. McCartney, *Editor*)

(Quarterly—ISSN 0003-1232)

The American Sociologist contains major articles analyzing sociology as a profession and as a discipline. Included are papers on such professional concerns as the use of sociological knowledge and skills in academic and non-academic settings; the conditions of work and maintenance of professional standards; the ethical, practical, and intellectual issues related to research; practical problems affecting sociologists as professionals (e.g., taxes, publication, copyright); ideological issues related to the development of new perspectives.

Recent issues have included articles on:

- *Field Work and the Protection of Human Subjects*
  DUSTER, MATZA & WELLMAN
- *Filthy Pictures or the Case of the Fraudulent Social Scientist: Unmasking the Phony Expert,* ST. GEORGE & McNAMARA
- *Representations of Merton's Theory of Anomie*
  HILBERT & WRIGHT
- *Universality of Science and the Question of National Sociologies,*
  HILLER

THE POLITICS OF WORKERS' PARTICIPATION

The Peruvian Approach in Comparative Perspective

By EVELYNE HUBER STEPHENS

A Volume in the STUDIES IN SOCIAL DISCONTINUITY Series

The Politics of Workers' Participation argues that workers' participation is a vital aspect in the distribution of power among social classes. Consequently, the development of workers' participation must be understood in the context of the struggle between sociopolitical forces to consolidate or transform a given social order.

The book illustrates four politico-economic systems: liberal-pluralist, authoritarian-corporatist, bureaucratic-centralist and democratic-socialist. Four stages of workers' participation—origins, purpose and design, development and effects, and supportive policies—are distinguished, and dynamics in these stages are linked to the functioning of sociopolitical forces at both the national-political and enterprise levels.

The book examines five specific cases: France, the Federal Republic of Germany, and Sweden to illustrate developed capitalist democracies; Yugoslavia as an example of a developing socialist authoritarian system; and Peru as an example of a developing capitalist authoritarian system.

1980, 304 pp., $29.50 ISBN: 0-12-666250-9

THE PROFESSIONAL STRANGER

An Informal Introduction to Ethnography

By MICHAEL H. AGAR

The Professional Stranger introduces an ethnographic perspective on the study of human life. Ethnography's goal is defined as the acquisition of an ability to interpret events as do members of some group. The perspective is further explored by contrasting ethnography with more traditional hypothesis testing approaches in the social sciences. Numerous examples are used, drawn for the most part from the author's field experiences in South India and with urban U.S. heroin addicts. While not intended as a methodological cookbook, several problems in ethnographic interviewing and observation are discussed. Throughout, there is a concern with the difficult task of providing systematic documentation of key ethnographic conclusions.

Museums of Madness
The Social Organization of Insanity in 19th Century England

Andrew Scull, *University of California, San Diego*

"*Museums of Madness* fills an important gap in the history of the insane. It is the first adequate account of the rise of the asylum in England, the country which led the world in adopting its use....This is an excellent contribution to the growing literature on an important subject."
—Peter McCandless in *Albion*

"*Museums of Madness* is sociological history at its stimulating best." —W. F. Bynum in *Psychological Medicine*

1979 ISBN 0-312-55355-2 275 pp., cloth $18.95

The View from Goffman
edited by Jason Ditton, *University of Glasgow*

Although the brilliance and originality of Erving Goffman's contributions to sociology and anthropology are widely recognized, his major contribution to the development of social theory is often unappreciated. The contributors to this book seek to correct that misimpression, to show that what Goffman has produced is not merely a series of unconnected snapshots of modern urban life. Their papers—all specially commissioned for this volume—constitute the first extended analysis of Goffman's sociology as a coherent body of theory.

1980 ISBN 0-312-84598-7 289 pp., cloth $25.00

Sociology and Theology
Alliance and Conflict

edited by David Martin, John Orme Mills and W.S.F. Pickering

This pioneering study brings together two disciplines not usually considered in intellectual conjunction in order to examine the new perspectives that each can offer the other. The essays made available in this volume, all published here for the first time, explore such questions as: how aware are theologians of the social determinants of theology? how useful are sociological enquiries based on what may appear to be theologically naive descriptions of related ideologies?

1980 ISBN 0-312-74007-7 204 pp., cloth $22.50

Identity and Authority
Explorations in the Theory of Society

edited by Roland Robertson, *University of Pittsburgh*, and Burkhart Holzner, *University of Pittsburgh*

In seven extensive, specially commissioned essays, this book explores the relationship between structures of authority in societies and various modes of personal identity. The contributions include analytical, theoretical and comparative discussions on the theme of identity and authority, as well as essays that focus particularly on recent shifts in American society in the relationship between societal macro-structures and individual modes of existence.

1980 ISBN 0-312-40448-4 318 pp., cloth $27.50

The Sociological Enterprise
C. C. Harris, *University of Swansea*

Over the past decade, C. C. Harris argues, the proliferation of sociological investigations of widely varying problems has obscured the nature of sociology as a systematic enterprise. His purpose in this book is to devise a way of organizing the concepts underlying the varieties of sociological practice in order to constitute a set of concepts fundamental to the aims of sociology as an academic discipline.

1980 ISBN 0-312-73968-0 about 240 pp., cloth $22.50

Corporations, Classes and Capitalism
John Scott, *University of Leicester*

In this study, John Scott examines the transformation of industrial property over the last hundred years, exploring the significance of this transformation for the actual structure of control over business decision-making. He investigates the roles of stockholders, bankers and financial institutions in an effort to identify the main patterns of power and influence in the economy; analyzes the relationships among indusrial property, the class structure and the state; and examines the role of the multinational corporation in the world economy.

1980 ISBN 0-312-17011-4 about 219 pp., cloth $22.50

POLICE-COMMUNITY RELATIONS

Crisis in Our Time

Third Edition

By **Howard H. Earle,** *California State Univ., Los Angeles. Foreword by* **William M. Conroy.** Divided into four sections, the newly revised edition of this monograph opens with a review of the general problems of police-community relations, including a look at past events influencing police-community relations and an analysis of misunderstandings and grievances between the public and the police. The author then describes the kinds of communication that help to create positive police-community relations. Guidelines for developing police displays, press releases, news media contact, agency tours, and other activities are presented. Sociological factors that thwart police objectives, such as the isolation of the police officer from the community, the behavior and dynamics of small groups, folkways, and prejudice, are then explored. A concluding section examines current efforts and future plans to establish improved relations between police and community. *'80, 304 pp., 5 il., 1 table, $16.75*

New! **MENTAL RETARDATION: A Phenomenological Approach** *edited by* **Jerry Jacobs.** Mental retardation and the problems it entails are discussed from the perspective of the mentally retarded individual and his/her family. *'80, cloth-$24.50, paper-$16.75*

New! **IMPROVING EFFECTIVENESS AND REDUCING COSTS IN MENTAL HEALTH** *by* **Brian T. Yates.** Procedures for assessing, analyzing, and improving effectiveness, while reducing costs, for a wide variety of mental health services are presented. *'80, $19.75*

New! **COMPETITIVE BEHAVIORS OF OLYMPIC GYMNASTS** *by* **John H. Salmela.** The physical, mental, emotional, and social behaviors of competing Olympic gymnasts are examined. Male/female and cross-cultural comparisons are discussed. *'80, cloth-$19.75, paper-$14.50*

OCCUPATIONAL HEALTH AS HUMAN ECOLOGY *by* **Stewart Wolf, John G. Bruhn** *and* **Helen Goodell.** The relationship of personal fulfillment and job satisfaction to a worker's health is analyzed. *'78, $14.00*

THE NATURE OF MAN: A Social Psychological Perspective *edited by* **Richard L. Gorsuch** *and* **H. Newton Malony.** Data relating social psychology to ethics, moral decision making, and the state of man's existence is herein presented. *'76, $16.25*

New! **BECOMING A WOMAN: The Socialization of Gender** *by* **Bernice Lott.** The female experience from conception through old age and those aspects of the socialization process common to American women are scrutinized. *'80, cloth-$24.75, paper-$18.50*

New! **POLICE SYSTEMS OF EUROPE: A Survey of Selected Police Organizations (2nd Ed.)** *by* **Harold K. Becker.** This text's cross-cultural perspective of European police organization, management, and operation will offer readers new insight on ways to solve police problems in the U.S. *'80, $13.75, paper*

New! **THE EFFECT OF AIR IONIZATION, ELECTRIC FIELDS, ATMOSPHERICS AND OTHER ELECTRIC PHENOMENA ON MAN AND ANIMAL** *by* **Felix Gad Sulman.** The effects of air electricity on crime rate, urbanization patterns, and health are among the topics covered. *'80, cloth-$24.75, paper-$18.75*

THE CHANGING STATUS OF THE BLIND: From Separation to Integration *by* **Berthold Lowenfeld.** The education, rehabilitation, and socioeconomic status of the blind as well as public policy and attitudes toward blinded individuals are examined. *'75, $30.00*

LAW, LANGUAGE AND COMMUNICATION *by* **Walter Probert.** The author presents an analysis of the subtle relationships between law and the dynamics of verbal communication. *'72, $17.25*

> "Rarely does a book combine such good theory, comprehensive scholarship, meaningful empirical data, and practical suggestions for social policy. Robin Williams has produced one of the best monographs in several years."
>
> (*American Journal of Sociology*, 1974)

The late Arnold Rose's evaluation of *Strangers Next Door* by Robin Williams, Jr., is equally applicable to Robin's contributions to the profession, and to his very active role in encouraging and stimulating others to do their best work.

Just 18 years ago, Robin Williams joined The Dorsey Press as its Advisory Editor in Sociology and Anthropology. His efforts and expertise have guided Dorsey in building an impressive list of more than 40 textbooks and monographs.

As he retires from his position with The Dorsey Press, we want to express our deepest appreciation and best wishes for a long and productive relationship which will continue to influence The Dorsey Press and American sociology.

Charles M. Bonjean, Hogg Professor of Sociology at the University of Texas and Vice President of the Hogg Foundation for Mental Health will succeed Robin as Dorsey's Consulting Editor.

Dr. Bonjean's qualifications are impressive, including the co-editing and co-authoring of seven books as well as numerous chapters and articles. Chuck is currently editor of the *Social Science Quarterly*.

During the last school year, Chuck and Robin have worked together to achieve a smooth transition at Dorsey. Chuck plans no major changes in the tradition established by Robin. The year has been a good one and we have every reason to believe that our contributions to sociology during the next two decades will match those of the past.

The Dorsey Press **Homewood, Illinois 60430**

From Prejudice to Destruction

Anti-Semitism, 1700–1933

Jacob Katz

This major reinterpretation of modern anti-Semitism blends the history of ideas with social analysis. Katz describes how a set of negative ideas about the Jews gradually became transformed and then, around 1870, gained so much social force as to result in the premeditated and systematic destruction of the Jewish people of Europe. $20.00

Constancy and Change in Human Development

Orville G. Brim, Jr., and Jerome Kagan, Editors

Orville Brim, Jerome Kagan, and an outstanding group of specialists in human growth assess questions of change and continuity in physical, mental, and emotional development throughout the life span. $27.50

Changing Youth in a Changing Society

Patterns of Adolescent Development and Disorder

Michael Rutter

"A thoughtful and thought-provoking assessment of the current state of knowledge on adolescent development and disorder...There is no better source for investigator and practitioner."—*Glen H. Elder, Jr.,* Cornell University $14.00

Coming this winter:

Family Impact Seminar Series

The influence of government policies on families and family life is examined in three separate volumes on foster care, teenage pregnancy, and work schedules.

Balancing Jobs and Family Life:
Do Flexible Work Schedules Help?
Halcyone H. Bohen and Anamaria Viveros-Long

This study compares 700 workers in two federal agencies in Washington, D.C., to evaluate the effects of flexible work schedules on family stress, personal schedules, and the sharing of chores and childrearing between parents. Through surveys and in-depth interviews, the book looks at how different kinds of households (single men and women, single-earner families, and especially dual-earner families) use flexitime. Approx. 325 pp. 3 photos January ISBN 199-5 $19.50

Beyond Alcoholism
Alcohol and Public Health Policy
Dan E. Beauchamp

Challenging the traditional concept of alcoholism, which blames the victim and ignores the social and cultural factors that influence alcohol use, this book goes beyond the study of drinking behavior to the larger issue of defining and understanding social problems in a public health context. Approx. 250 pp. November ISBN 189-8 $17.50

From Suburb to Shtetl
The Jews of Boro Park
Egon Mayer

An analysis of the broad sociological factors that shaped the transformation of a conventional residential neighborhood in Brooklyn, New York, into one of the most important orthodox Jewish communities. 208 pp. 7 photos 1979 ISBN 161-8 $15.00

Black Testimony
Voices of Britain's West Indians
Thomas J. Cottle

In their own words, more than twenty black men, women, and children living in London discuss their homes, families, education, work and unemployment, immigration to England, and their feelings about their white fellow-citizens. 184 pp. 1980 ISBN 186-3 $12.50

Temple University Press
Broad & Oxford Sts. Philadelphia 19122

The long-awaited translation of
MAURICE HALBWACHS'
THE COLLECTIVE MEMORY
Introduction by Mary Douglas
translated from the French by Francis J. Ditter, Jr. and
Vida Yazdi Ditter

A leading French sociologist of the 1920s and 30s and Emile Durkheim's foremost student, Halbwachs provided a major development in the theory of the sociology of knowledge. He separated the elements of social life that contribute to the collective memory, an achievement that has been largely responsible for contemporary sophistication on the subject. Here, in this work, is the essence of his thinking on collective memory. "No one before Halbwachs had dared to take on the question of considering how it is that the institutional framework of society affects memory . . . . he fashions new questions that no others in that tradition have examined." —Robert K. Merton

WE THE PEOPLES

Introducing

Harvard Encyclopedia of American Ethnic Groups

Stephan Thernstrom, Editor/Ann Orlov, Managing Editor/
Oscar Handlin, Consulting Editor

An indispensable reference work for home, library, and office, the Harvard Encyclopedia gives every ethnic group in the United States an honored place. And its authoritative accounts of origins, histories, culture, distinctive characteristics, and current status make lively reading indeed.

"There is literally no other work which approaches it in comprehensiveness. Even more impressive, however, is the quality of the articles. The editors should be congratulated."
—Seymour Martin Lipset

Harvard Encyclopedia of American Ethnic Groups. 87 maps 1076 pp.
$49.50 until December 31, 1980; $60.00 thereafter.

Marx Against Marxism

JULIUS LOEWENSTEIN
Leo Baek Prize Winner
Translated by Harry Drost

This book traces the origins, contradictions and consequences of Marx's teachings on his followers. Loewenstein uses Marx's own words to speak against the rigid dogmatism inherent in much of Marxism, and concentrates on the interpretations of Marx's work by Max Weber.
October $20.00

Sociology, Work and Industry

TONY J. WATSON
Lecturer in Industrial Sociology,
Trent Polytechnic, Nottingham

Designed as a text for sociology and social science students specializing in the fields of work, industry and organization, the author seeks to integrate these often disparate study topics.

This edition of an already successful textbook broadens its scope to incorporate recent sociological research.
$12.95, paper $5.00

London Patidars

A Case Study in Urban Ethnicity
HARALD TAMBS-LYCHE
Lecturer in Social Anthropology,
University of Bergen
Foreword by Professor John Rex

The Patidars, a landowning caste from India, have adopted a merchant ideology which, among those living in London, has become inseparable from their ethnic self-image. This book is an examination of how this form of ethnic boundary relates to the individual within it, and why it is maintained.
October $35.00
International Library of Sociology

The National Front

NIGEL G. FIELDING
Lecturer in Sociology, University of Surrey

This examination of one of Britain's most controversial political parties is aimed particularly at students of the sociology of deviance, political sociology and political science. It describes the ethnography, history, electoral performance and some demographic characteristics of its membership, and investigates key aspects of the party ideology — race, nationalism and conspiracy theory.

Exploring the City

Inquiries Toward an Urban Anthropology

ULF HANNERZ. In this bold first attempt to provide a coherent and unified theoretical basis for the study of urbanism, Ulf Hannerz draws together central ideas about the city and urbanism from anthropological, historical, sociological, and geographical sources. This wide-ranging analysis considers the contributions to urbanism from a variety of individuals, groups, and schools, including Weber, Simmel, Marx via the Chicago School, and the Manchester School. 384 pages, $15.00

Social Science Research and Decision-Making

CAROL H. WEISS with MICHAEL J. BUCUVALAS. This book examines the relationship between social science research and the choices and decisions of government officials and agency managers. It identifies the kinds of social science studies that officials pay attention to, explains when and how they find research studies useful, and shows how they apply the lessons of research to their work. 352 pages, $22.50

The Coming Crisis in British Penology

A. E. BOTTOMS, EDITOR. In essays ranging from "The Justice Model—Analysis and Development" to "The Future of Social Policy in Regard to Crime," ten British sociologists and social workers look at the future of justice and imprisonment in Britain. *Distributed in the U.S. and Canada for Scottish Academic Press.* 224 pages, $12.50 paper

DAVID NACHMIAS and CHAVA NACHMIAS, both of the
University of Wisconsin, Milwaukee

A basic text for courses in social science research methods, this widely praised book has been updated and expanded, taking into account the advice of both instructors and students who have used the First Edition. New chapters in the Second Edition cover the conceptual foundations of research, research design of pre- and quasi-experiments, questionnaire construction, and scaling and index construction.

Study Guide and *Instructor's Manual* available with the new edition.
February 1981 hardcover

Population
Demography and Policy
ROBERT H. WELLER, *Florida State University,* and
LEON F. BOUVIER, *Population Reference Bureau*

Taking a sociological perspective, Weller and Bouvier examine world and national patterns of population change, growth, and distribution. They look at the social and economic consequences of these trends as well as the individual and societal determinants of population behavior—fertility, mortality, and migration.

Instructor's Manual available. November 1980 hardcover

Society and Freedom
An Introduction to Humanist Sociology
JOSEPH A. SCIMECCA, *George Mason University*

This provocative new text introduces the basic elements and issues of the humanist perspective in sociology. It integrates fundamental sociological concepts with the themes of freedom, legitimacy, inequality, and political change to stimulate thoughtful class discussion.
February 1981 paperbound

Criminal Behavior
Readings in Criminology
edited by DELOS H. KELLY, *California State University, Los Angeles*

Criminal Behavior introduces the student to criminology through an appealing mix of theoretical essays and descriptive accounts of criminal careers. The articles illustrate how various types of crimes and criminal careers evolve, are maintained, and may be transformed.

August 1980 paperbound

Single Life
Unmarried Adults in Social Context
edited by PETER J. STEIN, *William Paterson College*

Single Life is the first comprehensive collection of essays dealing with the diverse population of single adults—a large, growing, and often misunderstood segment of today's society. The selections examine the life styles and major life issues of the divorced, separated, and widowed, as well as the never married.

February 1981 paperbound

The Sociology of Health and Illness
Critical Perspectives
edited by PETER CONRAD, *Brandeis University,* and ROCHELLE KERN, *New York University*

Organized around critical issues in the sociology of health and illness, these readings represent a variety of perspectives. Together, the selections explore the social roots and manifestations of the health care crisis in American society.

February 1981 paperbound

It's A Living
Work in Modern Society
GALE MILLER, *Marquette University*

It's A Living looks at the ways in which people make their livings and give meaning to their work. The text examines a wide range of activities, including professional and factory work, peasant labor, housework, and work in alternative communities.

February 1981 paperbound

New Books in Sociology . . .

Now Available

Understanding Abusive Families
James Garbarino and **Gwen Gilliam,**
Boys Town Center for the Study of Youth Development
288 pp. ISBN 0-669-03621-8 $19.95

The Maltreatment of the School-Aged Child
edited by **Richard Volpe, Margot Breton**, and **Judith Mitton**, University of Toronto
Foreword by **David G. Gil**
244 pp. ISBN 0-669-03463-0 $18.95

Discretion and Lawlessness: Compliance in the Juvenile Court
James T. Sprowls, The University of Wisconsin-Milwaukee
Foreword by **Daniel Katkin**
144 pp. ISBN 0-669-03540-8 $14.95

Jurors and Rape
A Study in Psychology and Law
Hubert S. Feild, Auburn University, and
Leigh Buchanan Bienen, Department of the Public Advocate, State of New Jersey
ISBN 0-669-01148-7 Now Available

Public Policy and the Family
Wives and Mothers in the Labor Force
Z. I. Giraldo, Duke University
240 pp. ISBN 0-669-03762-1 $22.95

Minimum-Drinking-Age Laws
An Evaluation
edited by **Henry Wechsler**, The Medical Foundation, Inc.
208 pp. ISBN 0-669-03380-4 $18.95

Economics and the Family
edited by **Stephen J. Bahr,**
Brigham Young University
208 pp. ISBN 0-669-03623-4 $19.95

Social Policies and Programs on Aging
Louis Lowy, Boston University
ISBN 0-669-02342-6 Now Available

Forthcoming

The Law and Politics of Abortion
edited by **Carl E. Schneider** and **Maris A. Vinovskis,**
Michigan Law Review Association
ISBN 0-669-03386-3 November 1980

Network Television and the Public Interest
A Preliminary Inquiry
edited by **Michael Botein** and **David Rice,**
New York Law School
Foreword by **Charles D. Ferris**
ISBN 0-669-02927-0 November 1980

Deviant Street Networks
Prostitution in New York City
Bernard Cohen, City University of New York-Queens College
Foreword by **Marvin E. Wolfgang**
ISBN 0-669-03949-7 November 1980

Adolescent Sexuality
A Study of Attitudes and Behavior
Helen F. Antonovsky,
Ben'Gurion University of the Negev
ISBN 0-669-04030-4 December 1980

Lexington Books

The Whole World Is Watching

Mass Media in the Making and Unmaking of the New Left

Todd Gitlin

"No phenomenon in American life cries for examination more than the impact of the news media on persons, movements and events. One need not accept all of Gitlin's provocative conclusions to praise the exacting scholarship that has gone into this study of what happens to an anti-establishment movement performing on an establishment stage." —*Daniel Schorr*

"Refreshingly supple and realistic." —*The Nation*
$12.95

Growing Old in Silence

Gaylene Becker

In this first book-length study of deaf people in old age, Becker describes how they adapt to their disability and analyzes its particular implications for becoming old. She adds an important new dimension to our knowledge of both aging and disability.
$10.00

Deafness and Child Development

Kathryn P. Meadow

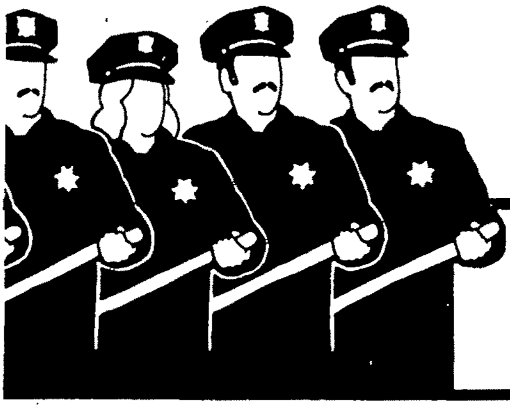
Meadow surveys the central work done on the social, linguistic, cognitive, and psychological effects of profound deafness in children and offers practical discussions with abundant concrete examples. The result is a book that provides a context for understanding research in childhood deafness and ways to apply its findings.
$12.95

Papal Power

A Study of Vatican Control over Lay Catholic Elites

Jean-Guy Vaillancourt

A thoughtful analysis of the papacy's manifold controls over the laity. Vaillancourt answers the fundamental question: "To accomplish its mission, does the Catholic Church need at its head a religious leader who also rules a temporal state and controls enormous wealth, or should it not divest itself of the trappings of power and wealth and function in a more egalitarian manner?"
$16.95



Breaking and Entering

Policewomen on Patrol

Susan Ehrlich Martin

Writing from a feminist as well as a sociological perspective Martin examines the problems female officers face "breaking and entering" into police patrol work, a job traditionally dominated by men.

SOCIOLOGY

A Text with Adapted Readings
Seventh Edition

by LEONARD BROOM, PHILIP SELZNICK,
& DOROTHY BROOM DARROCH

The book that defined the discipline is now extensively redesigned to be the most readable text in the field. Richly documented and systematically organized, the text reflects significant changes in context and organization. It retains its scientific orientation without sacrificing its academic integrity to become a "pop" sociology text.

Broom, Selznick, and new coauthor Dorothy Darroch have clearly modernized all subject areas and terminology in the text. All chapters have been significantly revised. This edition incorporates current and extensive research into new chapters on the life cycle, the sexes, deviance and diversity, and sociological methods. Points made in this visually striking full-color edition are reinforced with adapted readings—30 percent of which are new—and brief text inserts. To further reinforce comprehension, a glossary is included in this edition.

Also available: An instructor's manual with test bank and a study guide.

608 pages/tentative. ISBN 0-06-040991-6. February 1981.

To request examination copies, write to Suite 3D, Harper & Row, 10 East 53d Street, New York, N.Y. 10022. Please include course title, enrollment, and present text.

Notice to Contributors

A processing fee of $10 is required for each paper submitted, except for comments; such fees will be waived for student members of ASA. A check or money order, made payable to the American Sociological Association, should accompany each submission. The fee must be paid in order for the review process to begin.

The length of an *ASR* paper is generally ten (10) printed pages or thirty (30) typed pages. However, the *ASR* is happy to accept manuscripts up to fifty (50) typed pages in length for review. We also are interested in receiving manuscripts for a Research and Notes Section.

To permit anonymity in the review of manuscripts, keep identifying material out of the manuscript. Attach a cover page giving authorship, institutional affiliation and acknowledgments, and provide only the title as identification on the manuscript and abstract.

ASA Multiple Submissions Policy: Submission of a manuscript to a professional journal clearly implies commitment to publish in that journal. The competition for journal space requires a great deal of time and effort on the part of editorial readers whose only compensation for this service is the opportunity to read papers prior to publication and the gratification associated with discharge of professional obligation. For these reasons, *the American Sociological Association regards submission of a manuscript to a professional journal while that paper is under review by another journal as unacceptable.*

SUBMISSION AND PREPARATION OF MANUSCRIPTS

1. Submit four (4) copies and retain the original for your files. Copies may be Xerox, mimeograph or multilith, but not carbons.
2. Enclose a stamped self-addressed postcard for acknowledgment of manuscript receipt. *Manuscripts will not be returned.* Please do not send your original copy.
3. All copy must be typed, doublespaced (including indented material, footnotes and references) on 8½ by 11 inch white opaque paper. Lines must not exceed six (6) inches. Margins must be a minimum of one inch.
4. Include four (4) copies of an abstract of no more than 150 words.
5. Type each table on a separate page. Insert a location note at the appropriate place in the text, e.g., "Table 2 about here." Send copies, retain originals.
6. Figures must be drawn in India ink on white paper. Send copies, retain originals.
7. Clarify all symbols with notes in the margins of the manuscript. Circle these and all other explanatory notes not intended for printing.
8. Footnotes should not be placed in the body of the text. Type them (doublespaced) and attach them as a separate appendix to the text. Number them consecutively throughout the text. Footnotes are to be kept to a minimum and used only for substantive observations. Source citations are made within the text rather than in footnotes.
9. Acknowledgments, credits and grant numbers are placed on the title page with an asterisk.

REFERENCE FORMAT

A. *In the text:* All source references are to be identified at the appropriate point in the text by the last name of the author, year of publication and pagination where needed. Identify subsequent citations of the same source in the same way as the first, not using *"ibid.," "op. cit.," or "loc. cit."* Examples follow:

1. If author's name is in the text, follow it with year in parentheses. [". . . Duncan (1959) . . ."]
2. If author's name is not in the text, insert, in parentheses, the last name and year, separated by a comma. [". . . (cf. Gouldner, 1963) . . ."]
3. Pagination (without "p." or "pp.") follows year of publication after a colon. [". . . Kuhn (1970:71)."]
4. Give both last names for dual authors; for more than two use "et al." in the text. When two authors have the same last name, use identifying initials in the text. For institutional authorship, supply minimum identification from the beginning of the complete citation. [". . . (U.S. Bureau of the Census, 1963:117) . . ."]
5. Separate a series of references with semicolons and enclose them within a single pair of parentheses. [". . . (Burgess, 1968; Marwell et al., 1971; Cohen, 1962) . . ."]

B. *In the appendix:* List all source citations by author, and within author by year of publication, in an appendix titled "References." The reference appendix must be complete and include all references in the text. The use of "et al." is not acceptable in the appendix; list the names of all authors. (See A. 4. for text format.)
If there is more than one reference to the same author and year, distinguish them by the letters, a, b, etc. added to the year. [". . . Levy (1965a:331) . . ."] Give the publisher's name in as brief a form as is fully intelligible. For example, John A. Wiley and Sons should be "Wiley." If the cited material is unpublished, use "forthcoming" with name of journal or publisher; otherwise use "unpublished."
Use no underlining, italics or abbreviations.
Examples follow:

1. *Books:* Jud, Gerald J., Edgar W. Mills, Jr. and Genevieve Walters Burch
   1970 Ex-Pastors. Philadelphia: Pilgrim Press.
   U.S. Bureau of the Census
   1960 Characteristics of Population. Volume 1. Washington, D.C.: U.S. Government Printing Office.
   Bernard, Claude
   [1865] 1957 An Introduction to the Study of Experimental Medicine. Tr. Henry Copley Greene, New York: Dover.
2. *Periodicals:* Conger, Rand
   Forthcoming "The effects of positive feedback on direction and amount of verbalization in a social setting." Pacific Sociological Review.
   Merton, Robert K.
   1963a "The ambivalence of scientists." Bulletin of The Johns Hopkins Hospital 112:77–97.
   1963b "Resistance to the systematic study of multiple discoveries in science." European Journal of Sociology 4:237–82.
3. *Collections:* Davie, M.
   1938 "The pattern of urban growth." Pp. 133–61 in G. Murdock (ed.), Studies in the Science of Society. New Haven: Yale University Press.

See recent issues for further examples. **Revised 1980 ASR**

SCOPE AND MISSION OF AMERICAN SOCIOLOGICAL REVIEW: The *American Sociological Review* publishes work of interest to the discipline in general, new theoretical developments, results of research that advance our understanding of the most fundamental social processes, and important methodological innovations. Like other publications of the Association, emphasis is given to exceptional quality. Unlike the more specialized journals of the Association, the *American Sociological Review's* primary focus is on whatever has the most general bearing on the knowledge of society.

Concerning manuscripts, address: Editor, *American Sociological Review*, Department of Sociology, University of Illinois, Urbana, Illinois 61801. (217) 333-6515.

The *American Sociological Review* (ISSN 0003-1224) is published at 49 Sheridan Avenue Albany, New York, bimonthly in February, April, June, August, October, and December.

Applications for permission to quote from this journal should be addressed to the Executive Office

Copyright © 1980 American Sociological Association.

Annual membership dues of the American Sociological Association, $20–$120 ($10 of this amount may cover a subscription to the *American Sociological Review*); Associate, $25; International Associate, $25; Student Associate, $12.

Application for membership and payment of dues should be made to the Executive Office. Subscription rate for members, $10; nonmembers, $15; institutions and libraries, $30; nonmember students, $10. Single issue, $4.

New subscriptions and renewals will be entered on a calendar year basis only.

Change of address: Six weeks advance notice to the Executive Office and old address as well as new are necessary for change of subscriber's address.

Concerning advertising, changes of address, and subscriptions, address: Executive Office, American Sociological Association, 1722 N Street, N.W., Washington, D.C. 20036.

Claims for undelivered copies must be made within the month following the regular month of publication. The publishers will supply the missing copies when losses have been sustained in transit and when the reserve stock will permit.

Second class postage paid at Washington, D.C. and additional mailing offices.

AMERICAN SOCIOLOGICAL REVIEW

THE PRESIDENTIAL ADDRESS: THE CHALLENGE AND OPPORTUNITIES OF APPLIED SOCIAL RESEARCH*

PETER H. ROSSI
Social and Demographic Research Institute
University of Massachusetts–Amherst

American Sociological Review 1980, Vol. 45 (December):889–904

Introduction

The stance of our profession toward applied work of all sorts in sociology has been one of considerable ambivalence. On the one hand, applied work is decidedly below basic or theoretical work in the hierarchy of preference, prestige, and esteem. Correspondingly, academic employment is very strongly preferred over nonacademic positions, even though salary levels for the latter are often considerably higher. When we scan the credentials of job applicants or bibliographies appended to grant applications, articles published in journals that feature applied work are assumed to be of lesser quality than ones published in mainstream professional journals. Most sociologists are embarrassed when we are confused with social work or with family therapists. Indeed, some of our colleagues gloss over their applied work as if it were a vice best kept from public view.

On the other hand; our roots in applied concerns are old and very much alive. Our ranks always have been full of ministers and ex-ministers, radicals and ex-radicals, even a few conservatives and ex-conservatives, all of whom were attracted to sociology because our discipline appeared to have some relevance to social reform or its prevention. And when it comes to facing outward toward the public—and especially toward our benefactors—we are very quick to point to the many complicated social problems that justify our existence and need for support. Our public stance is often enough that a properly supported sociology will point the way to a better society with a lowered level of social troubles.

Thus, our ambivalence consists in believing—at one and the same time—that applied work is not worthy of our best efforts and our best minds and that an important reason for our existence is that sociology will lead to important practical applications.

Some of our critics apparently understand this ambivalence sufficiently to be able to exploit it and, occasionally, will criticize us on both counts. For example, earlier this year, Congressman Ashbrook (Ohio) spoke out in support of his proposal to slash the NSF appropriation for the basic research program in the social and behavioral sciences—a sterile title that hides sociology, political science, and economics in a plain brown envelope. He accused us (on the one hand) of being off in the cloudy heights of theory and speculation and, hence, not attending to the very real needs of our society, yet (on the other hand) of seriously endangering the moral order of our society by implicitly endorsing, through research on such matters, the dreadful patterns of deviance that afflict our society.

It should be pointed out that sociology

---

* Direct all correspondence to: Peter H. Rossi; Social and Demographic Research Institute; University of Massachusetts; Amherst, MA 01003.

Presented as the Presidential Address to the American Sociological Association at its annual meeting in New York City, August, 1980.

Grateful acknowledgements are due to James F. Short, Alice S. Rossi, Stanley Lieberson, Clark C. Abt, James D. Wright, Howard Freeman, and Richard Berk whose comments on an early draft helped to improve this paper.

is not the only discipline that holds an ambivalent view of applied work: this is a viewpoint we share with the other social sciences and with the natural physical sciences as well.

There must be some important reasons why this ambivalence persists, over time, in sociology and other disciplines. I will leave it to the sociologists of science to provide an understanding of why we have such mixed feelings toward applied work. My task here is to examine more closely the relationships between applied and basic work in our field, through taking up four themes:

First, I will explore what the differences are between basic and applied work, showing that the lines between the two are difficult, if not impossible, to draw.

Second, I will attempt to show that there has been considerable commerce between the two parts of our discipline, to the considerable enrichment of both. For polemical reasons, I will emphasize the contributions that applied research has made to basic sociology, an argument that may not give appropriate attention to the fact that the commerce between basic and applied work is certainly a two-way exchange. No one knows whether, in the long- or short-run, the balance of trade favors the one or the other side of the exchange—although there are many opinions on this issue.

Third, I will belabor the obvious a bit, pointing out what many of us already know quite well—namely, that applied social research has enjoyed a boom period over the last two decades, a prosperity in which sociology as a discipline has not participated strongly.

As my final theme, I will point out some of the implications of the current boom in applied social science for our field, indicating why we should become more involved and how we can do so.

There are several varieties of applied work in sociology, including clinical practice, policy analysis, consultation to businesses and government agencies on substantive issues, and applied social research. My main concern will be with applied social research, although many of the points made are, most likely, relevant to other kinds of applied work in sociology. I confine myself to applied social research mainly because I know more about that subfield of applied sociology.

The general argument running through this article is that applied social research has been a firm and fruitful part of the tradition of our discipline. Practitioners and their applied social research have not been given sufficient credit for their contributions to the development of our discipline. I argue for greater recognition to be given to applied social research—in the form of more attention to that activity within our curricula, in our professional journals, and in the rewards our profession gives for scholarly accomplishments.

A Modest Contribution toward Conceptual Clarity

It is easy to distinguish between applied and basic work in sociology if you consider only extreme cases. Using examples from my own work, it appears to be quite obvious that *After the Clean-Up . . .* (Wright et al., 1979) is applied social research, being an attempt to estimate the long-term effects of natural disasters (tornadoes, floods and hurricanes) on the population and housing stocks of small areas. It is, clearly, applied research because its main purpose was to assess whether there was any need for changes in federal policy to provide aid to communities and neighborhoods ameliorating the impacts of long-term negative effects of such natural-hazard happenings. In contrast, an apparently clear example of basic research is my recent article (Alves and Rossi, 1978) on uncovering the normative bases for distributive justice judgments concerning household earnings. What is it that appears to differentiate between the two examples? First of all, the research on the long-term effects of natural disasters was designed to serve an existing need for information for social policy decision making while the distributive justice study is far from current policy concerns. In contrast, income redistribution issues involving wage rates are not explicit issues on current political agendas of legislatures. Nor is there any consideration given to regulating earnings in the interest of increasing popular feelings about how just income discrepancies are among households. The fact that we found no discernible long-term community effects, stemming out of a decade's experience with natural disasters, meant that no relief measures designed to meet the needs of small areas were necessary. In contrast, there likely are no policy makers who are currently concerned with altering wages in order to increase the average sense of justice.

Note, however, that implied in the foregoing is the argument that for a given research to be clearly applied requires the existence of policy makers who would be interested in the outcome as well as in the possibility or existence of some policy to which the research was immediately addressed. So far, this does not appear to be a very satisfactory definition as its main provisions are not linked to the research activities per se but, rather, to the purposes to which the research might be put by some segment of our society. Indeed, this consideration points to the historical specificity of just what is often called applied social research. Because the interests and concerns of policy makers and other political partisans change, over time, research that is applied in one historical period may be basic research in another period—and vice versa. Legislatures might not be concerned *currently* with establishing new (and presumably more equitable) principles for setting wages and salaries, but it is certainly conceivable that they *might* do so. In that event, Alves and Rossi's (1979) study would become applied social research! (We will return again to this issue of historical specificity.)

A second point of difference between the two research examples lies, in the first instance, in the existence of a "client" who underwrote the costs of the research and who also had a direct interest in the outcomes of the research. The NSF-RANN program financed the research that went into the *After the Clean-Up* study because it showed promise (indeed, we actually *did* promise) to be relevant to policy issues. But the social science panel of NIMH that approved the distributive justice study apparently "couldn't have cared less" whether the research was needed for social policy or not. Nor did that grant application promise policy-relevant findings.

Having a client who is concerned about the outcome of a research project that he or she has sponsored often means a continuing connection between the researcher and client throughout the conduct of the research project. While the connection may take a variety of forms, all the way from "oppressive" supervision at the one extreme and benign neglect at the other extreme, applied research always means that somewhere there is less autonomy for the applied (as compared with the basic) researcher.

In applied work, there is more time-consciousness, deadlines to be met, interim and final reports to clients to be written; and, often, there is some specific person or group that is intensely enough interested in your work to attempt constantly to find out what you are up to, and doing, in quite specific terms. In contrast, even though basic researchers have to report to someone and be responsible in a general way for doing a job, the detail and constancy of supervision is simply not as great. I am sure that this is one of the reasons that applied research is valued less than basic research in which the autonomy of the researcher is always greater. Although the NSF-RANN program was far from the most intrusive clients I have had dealings with, my colleagues and I did have to suffer, albeit mildly, through a succession of advisory committee meetings, conferences with RANN staff members, and consultations with federal agencies that were concerned with disaster relief.

Basic research presents quite a contrast. I never again heard from NIMH, once the distributive justice grant was awarded. As requested, I sent copies of articles published as a result of work done under the support grant. If anyone on the NIMH staff actually read any of them, he/she certainly did not feel impelled to communicate either pleasure or displeasure or, for that matter, any other reaction. From almost any researcher's point of view, it is better to operate either without a client or with a very unintrusive client. Certainly, in that sense, basic research is to be preferred over applied research.

The major implication that flows from this discussion, so far, is that whether or not a given research or scholarly work is regarded as basic or applied is, at least partially, historically bound. Thus, subsequent history may treat very differently research conducted in an earlier period. For example, the now-classic 1947 NORC (Reiss, 1961) study of occupational prestige was originally applied social research conducted for a federal agency concerned at the time with the recruitment of natural scientists to federal employment. The agency was convinced that the prestige of federal employment had suffered a severe blow in the years immediately following World War II and had sponsored the research simply to get a better reading on how government scientists were viewed by the general public—as compared with their views of scientists who worked for private industry or for universities. What was, originally, a piece of applied work done for a particular client has become, with time, primarily basic research—at least in the way it has been viewed in the sociological literature.

Indeed, the NORC-North-Hatt occupational prestige research is rather instructive as an illustration of the interpenetration of applied and basic interests. It certainly would have been possible for NORC to have undertaken a study of occupational prestige that was focused exclusively on the occupations of interest to the client. However, the researchers in charge of the project convinced the client that the agency's interests would be better served by a research design that placed the occupations of policy interest into the context of the entire occupational structure. This enlargement of the original narrowly focused interest of the client into a much larger framework was guided largely by North and Hatt's interests in social stratification. The resulting study, of course, was considerably enhanced in value for basic sociology as a consequence.

Another example of applied research becoming basic is W. Lloyd Warner's study of Newburyport (Warner and Lunt, 1941). The immediate motivation for the Yankee City studies was to add a community context to the study of industrial work forces, an interest that had grown out of the Mayo and Roethlisberger Western Electric Hawthorne studies (Roethlisberger and Dickson, 1939). One can dispute whether or not the Yankee City studies were even at all relevant to the applied concerns they were designed to serve, but the fact remains that, initially, Warner was working for a client with quite specific interests and the Yankee City studies were initially conceived of as applied research.

The course of history may also turn a basic study into an applied one. Thus, Benjamin Bloom's work (Bloom, 1964) on the stability of IQ during early childhood became one of the intellectual pillars of President Johnson's Head Start program, as policy makers and their staffs searched through existing literature to find data on where best in the lives of children to intervene with compensatory educational programs. Bloom's work noted the apparent stability of IQ from the first grade on, suggesting that preschool intervention would be most effective. In the same way, E. Franklin Frazier's monograph (Frazier, 1939) on the Negro family had almost slipped into scholarly oblivion when revived by Moynihan (Moynihan, 1965) to provide an apparent explanation of why there was so much "pathology" among contemporary black families.

I started out this discussion of the differences between basic and applied social research with examples in which the distinction is easy to make. For many researches, particularly large-scale studies, the distinctions are much more difficult to draw and, at the margins, the lines between applied and basic research are almost impossible to discern. For example, the Income Dynamics Study (Morgan et al., 1974) was sponsored initially by the Office of Economic Opportunity to provide information on how often, and why, families apparently drifted back and forth across the poverty line. Currently, this longitudinal study is being supported as basic research by the Social Science Division of the National Science Foundation. There can be little doubt that this study has simultaneously contributed to applied concerns and basic social science, aided considerably by the wide diffusion of public use data sets. Essentially nothing about the design changed as sponsorship shifted from OEO to NSF, nor was there much shift in subject matter. The question of whether this is basic or applied social research is somewhat irrelevant—as it seems to have been both. Of course, it should be emphasized that the principal investigators played an important role in designing the study (and its continuation) so that findings would be relevant both to current social welfare policy and to a host of basic concerns in several social sciences.

Another interesting example is the Equality of Educational Opportunity report (Coleman et al., 1966) and the data sets lying behind that report. In its inception, Coleman and Associates' study was certainly applied, mandated as it was in the 1964 equal rights legislation. While there were some policy concerns expressed specifically in the federal legislation it was relatively general in character, calling as it did for a survey to ascertain whether or not educational opportunities were equal across ethnic groups. The design created—and the analysis followed—by Coleman and his associates went considerably beyond the mandate of the Congress to provide, among other things, estimates of the effects of schools on the achievement of pupils. Is this an example of basic or applied research? The answer is that it is both: it is applied research—by virtue of having a client and a set of policy concerns to which the research was at least partially directed; but it is also basic research—in that the researchers went beyond a narrow research mandate to consider some general issues in the sociology of education.

Special note should be taken of the important role played by the researchers in the design of applied social research. A particular applied-research study may be so narrowly designed that basic sociological (or other social science) concerns would find very little of interest in the study or in its findings, or it can be designed to accommodate basic concerns as well. Indeed, given the fact that policy concerns are often vaguely stated and, furthermore, often shift over short periods of time, broad-focused applied studies are likely to be more useful to policy interests, as well as being of greater disciplinary interest.

I hope that I have given sufficient examples to illustrate that the line between basic and applied research is a fuzzy one, subject to redefinition by the researchers, by clients, and by the drift of historical change. The implication of such fuzzy boundaries is that it is difficult to decide what is applied work and what is not. Good applied work tends to be transformed into basic contributions, a process that does not disturb the conventional view of applied social research being, somehow, lower in value and quality than is basic research. A proper recognition of the origins of much of the work that we value in our history would support a more positive view of the contribution of applied work to the growth of our discipline.

Of course, the counter-arguments can be made that (1) I have selectively skimmed the best of applied social research in order to bolster unfairly the argument I have presented, and (2) the bulk of applied social research is of poor quality and hardly likely to contribute even to the discipline, let alone to the solution of social problems. There is some truth in this argument: Much of applied social research is best left in the fugitive Xerox reports in which they were issued. But low quality and irrelevance are characteristic of most of the work in our discipline, whether applied or basic. For example, more than three-fourths of all articles submitted to *ASR* are turned down. Whether or not applied work has more low-quality output than does basic work is problematic.

Some General Contributions of Applied Social Research to Basic Concerns

Because the line between basic and applied work in sociology is fuzzy and indeterminate, it is correspondingly difficult to make a definitive assessment of the interchange between basic and applied work. Today's applied work may be tomorrow's basic science—and vice versa.

Furthermore, what I may classify as "basic" may be defined by another sociologist as "applied." Indeed, about the best one can do is to provide examples of notable transactions in which applied work has made obviously significant contributions to basic social science concerns, in the optimistic hope that these outstanding examples are fair indicators of what is true generally.

To begin with, it is important to recognize that many of the most prominent sociologists have devoted some significant portions of their careers to applied social research: Even an incomplete listing of such persons is quite impressive, including Durkheim, Giddings, Ogburn, Stouffer, Park, Hughes, Lazarsfeld, K. Davis, Phillip Hauser, Sewell, O. D. Duncan, and Coleman. Indeed, a rough and informal count I made of the last thirty Presidents of the American Sociological Association yielded an estimate that eighteen had been involved significantly in applied social research. Clearly, this is an underestimate, relying as it does on the fallibility of one observer's memory. Among the remaining twelve, there are a few who did some applied work—as, for example, Pitirim Sorokin, though his general work was certainly not of that vein. Indeed, there are likely more than a few among the twelve others who may have been "closet" applied social researchers.

Most interesting and revealing, in light of the earlier discussion about the lower esteem accorded to applied work, is that so many of the eighteen Presidents are not generally remembered as applied social researchers because, over time, some of their most important applied research has been redefined as basic work. For example, how many of us recall (or ever knew) that Lazarsfeld's seminal work on personal influence (Katz and Lazarsfeld, 1955) stemmed from very applied work financed by MacFadden Publications in an effort to obtain evidence that would convince would-be advertisers that placing ads in *True Story* magazine would reach opinion leaders? Or that the very influential series of researches by Sewell and his associates (Sewell et al., 1976) on status attainment had its beginnings in a state-sponsored survey of Wisconsin high school seniors, the major purpose of which was to forecast the demand for higher education in that state?

One of the more visible characteristics of prominent sociologists who have participated in applied work is the predominance of quantitative empirical researchers in that group. This is a feature of some importance, as I will develop more fully, later in this discussion. For the present, this characterization is noteworthy as evidence that one of the most important contributions of applied research has been to technical developments in research methods.

Most of us are familiar with the fact that much of the basic work in statistical methods has come out of applied concerns in other fields, experimental work in agriculture, psychological test construction, quality control in industry, and so on. The outstanding examples are quite numerous, as the following list demonstrates: Student's T, analysis of variance, factor analysis, regression, and on and on. By and large, sociologists have been net borrowers of research methods vis-à-vis other fields, especially with respect to statistical models.

Sociologists have played a more important role in the development of data collection methods. Along with other social scientists, we have made important contributions to the science and art of sample surveys. Much of the early work that went into the development of sampling methods, interview construction, and the like was undertaken within applied contexts, by sociologists in collaboration with other social scientists. Area probability sampling was developed at the Bureau of the Census out of a need to conduct valid periodic estimates of the labor force. Psychologists and sociologists—working for the most part with the advertising industry, newspapers, and political candidates—developed the attitude survey. Scaling methods, at least in part, developed out of the work in Stouffer's (Stouffer et al., 1950) Research Branch in the Information and Education Division of the War Department. Indeed, the Research Branch, a decidedly applied activity, did a great deal to train a fairly large set of young sociologists who became the postwar specialists in sample surveys and, more generally, helped to establish the use of sample surveys of all sorts as a prime research tool for our field. The most recent development in sample surveys, random digit dialing, was developed initially by persons working on commercial sample surveys; it is now gradually finding its way into use by sociological researchers.

In addition, one must recall that Hollerith was a Census employee when he came up with the idea of the punch card and mechanical tabulating equipment. And the first commercial version of the electronic computer, UNIVAC I, was at least partially speeded toward development by the demand for its use in the 1950 Census of Population and Housing.

Other frequently used techniques in social research were also either developed in pursuit of applied interests or heavily influenced by being used in applied research. For example, the intense postwar public policy interest in the issue of overpopulation gave a large impetus to the further development of demographic methods. Sociometric techniques had their start as Moreno (1934) developed a device for optimizing the residential arrangements of young women in a training school. Social field experiments had an early start with Dodd's (1934) randomized experiment in Syria on techniques for instilling appropriate drinking water treatment procedures in rural areas.

Qualitative research methods also have roots in applied work. The earliest American community study (Williams, 1906), conducted by a rural sociologist housed in an experimental station, was concerned with the impact of changing agricultural technology on a rural town. As mentioned earlier, Warner's study of Newburyport grew out of the Mayo and Roethlisberger work on worker productivity. The Lynds' first Middletown study (Lynd and Lynd, 1938) was financed by a foundation with a concern for studying the impact of social change on the moral life of Americans.

The technological and methodological contributions of applied to basic sociology loom large because new methods are easier to transfer across substantive fields. In contrast, theory and empirical knowledge are more closely tied to substantive fields and, hence, do not travel as easily. Perhaps most of the transfer from applied to basic work in substantive theory and empirical findings has occurred because much applied work has dealt with subject matters that are at the very heart of sociological concerns—stratification and inequality, organizations, collective behavior, deviance and social control, race relations and discrimination, life chances and health care, family, work and occupations, and so on. Indeed, there are few substantive areas that have not been studied with an applied focus.

Yet, it is difficult to point out clear one-way contributions of applied work to basic work—mainly because the interchange has been an interactive one. Some contributions of applied work (such as the concept of personal influence and opinion leadership) are directly and easily traceable to the applied work from which they originated. Others (such as the concept of relative deprivation) are indirect contributions arising out of commentaries upon or secondary analyses of applied work. In still other cases, concepts arising in theoretical work have been refined in applied work—and vice versa. Examples of the joint development of concepts include status attainment, occupational prestige, and anomie. Other examples, I am sure, will occur to the reader. Of course, one of the more important contributions of applied social research has been to the refinement of—and sometimes negations of—concepts derived from general sociology. The empirical testing of concepts that are incorporated into applied research has led often enough to their being disconfirmed. For examples: there is little empirical evidence for labelling theory, virtually no evidence for a "culture of poverty," meager support for differential association, and so on. Although it would certainly be an exaggeration to state that sociology would not have advanced at all over the past three decades without the help of applied work, it would be equally foolish to claim that applied work has not made a strong contribution to the progress that sociology has made in that period. Basic and applied work in our discipline are complementary endeavors.

Some Challenges and Pitfalls of Applied Social Research

The products of applied social research have made, as I have attempted to show, strong contributions to the development of our discipline. Although the hope of making such contributions might be sufficient to motivate one to engage in applied social research, there are also some intrinsic satisfactions to be derived from the inherent nature of applied work. There are also some pitfalls of which the would-be applied social researcher must at least be aware. Both the attractions and the dangers of applied social research have their roots in the politicized nature of such research, as I will now attempt to show.

Applied social research often demands greater technical skills than does basic research. Because the results of applied social research may be used in the political process, it is clearly important that it be done well. After all, an article in a major professional journal, or a monograph, has little consequence except upon the career of the writer and, perhaps, except for attracting the attention of the handful of other social scientists who have been doing work on the same topic. In contrast, the product of applied social research might be used in the formation and change of public policy; and an error in applied work might have consequences not only for the social scientists involved but also for institutions, agencies, policy makers, and the intended beneficiaries of the policies in question.

Although the discipline may be concerned with whether research reported upon in an *ASR* or *AJS* article is based on good samples, used good measurement instruments, used a research design of appropriate power and methods of analyses that are robust, such concerns are not as salient as in applied work. This is one of the main reasons why much applied social research is on a so-much-larger scale than discipline-oriented research. Of course, editors and readers do deduct points for defects in any of these respects, but the fact of the matter is that there are so few good ideas and data in sociology that Type I errors are clearly less important than Type II errors in the judging of articles. In contrast, for example, estimating the work disincentive effects of transfer payments calls for good samples, precision and validity in measurement, and virtuosity in analysis—because an error in any of these might be translated into social policy affecting the well-being of poor households across the nation.

Of course, the fact that applied social research may be used in policy formation is also one of the pitfalls into which it is easy to stumble. It is very easy to become the center of rancorous controversy; contending parties in some policy dispute may use and abuse your work. There are few major applied researches that have not sparked controversy, as, for example, in the cases of the Coleman Report, the evaluation of Head Start, or the Income Maintenance experiments. Indeed, the controversial character of applied social research has spawned part-time employment of researchers as methodological critics hired by partisans to provide devastating criticisms of some applied social research.

Conflict over the results of applied social research is not without its positive side, however. The competition among divergent points of view has led to a considerable acceleration of progress toward higher and higher quality in applied social research. For example, the heavy criticism directed at quasi-experimental estimates of program effectiveness has sparked considerable progress toward understanding the role of a priori theory in devising research designs (Heckman, 1980).

New methodologies have been invented, old ones adapted to new problems; and interdisciplinary transfer of ideas has been accelerated through the critical evaluation of applied research. Of course, so-called basic and theoretical work is also subject to criticism, but the critical process for applied work is more timely and more intense, characteristics which may be somewhat more painful to the applied social researcher but which are more productive of relatively rapid progress in technical and conceptual quality.

The political character of applied social research is the source of another of its attractions, at least to those of us who are still concerned with improving our society. There is the possibility that the results of applied social research will do some good. Thus, one might be tempted to undertake research on the child-care arrangements used by working mothers in the hope that the resulting findings might pave the way for better and more effective child-care policies. There are, however, some restrictions on what one can do as an applied social researcher. First of all, problems are not set by the researcher alone but, often, are worked out on the initiative of some policy-oriented agency and, sometimes, by negotiation between the researcher and the agency in question. In practice, this means that, as an applied social scientist, one is not entirely free to frame research problems in the form that appears most fruitful to the researcher. One is ordinarily restricted to what is called "policy space"—that is, the range of alternative remedies for a social policy that appears to be politically acceptable. Thus, for example, the income maintenance experiments defined a set of payment plans that were thought to span what would be acceptable to Congress, a space that did not include what you and I might consider to be very generous payment plans. In short, there are politically imposed limits on subject matter and policy issues that can be considered in applied social research.

Applied social research tends to be conservative, devoted mainly to the examination of policy alternatives that are not radically different from existing social policies. Fine tuning, rather than revolution, is on the political agenda. At best, applied social research is politically congenial, both to those who are liberals and to the right of liberals.

While applied social research will not bring about revolutionary changes, it is in practice neither reactionary nor completely supportive of the status quo. At least in the present historical period, applied social research has had the characteristics of being a demystifying instrument, exposing the faults and inadequacies of existing institutions. Criminologists in their research have had profound impacts on American prisons. Applied research on schools has raised fundamental questions about what schools do. Applied research on alcoholism has certainly changed our understanding of that disorder. Such examples can be easily multiplied. The fact of the matter is that the social policy of the past few decades was conceived by persons with—at best—amateur social scientist status and, hence, most of it (as well as most long-standing institutions) cannot stand up very well under the scrutiny of a thoroughgoing empirical testing.

It should be kept in mind, however, that applied social research is no occupation for would-be philosopher kings. The applied researcher ordinarily does not get very close to the seats of decision making and policy formation. Often enough, policy appears impermeable to both the results of research and the advice of the researcher. Even at its best, applied social research does not substitute for the political process. It merely provides another input into the policy-making process. Indeed, who would have it otherwise? One of the virtues of our political system is that decisions are made often enough as the outcome of the pulling and hauling among a variety of interest groups, a process that may value the input of social science work but does not place the work on a pedestal of absolute authority.

It is not at all clear to me how one may measure whether the attractions of applied social research are outweighed by the negative aspects of politicized work, or vice versa. If you are attracted both to technically challenging work involving the fine tuning of our existing society and to the opportunities presented by relatively high levels of resources, and are not put off by the possibility that your work will be seemingly ignored by decision makers and possibly come under attack from fellow social scientists, then applied social research is an attractive activity. If you cannot stand verbal and written abuse, or want to work on fundamental changes in our society, then applied social research is clearly not for you.

These foregoing remarks are addressed to the question of whether one would or would not find the politicized aspects of applied social research a deterrent to participation. The negative consequences account, in part, for the reasons that applied social research is undervalued in our discipline. But such arguments do not address themselves to the scholarly contributions such work may make to the growth of our discipline. Applied social research is harder on the participant, but that is at least partially balanced by the greater intellectual challenges such work may provide and by the positive contributions it may make to our society and to the discipline.

The TARP Experiments: Concrete Illustration

The technically challenging nature of applied social research (as well as some of its politicized aspects) is perhaps best conveyed through a concrete illustration. I will draw upon work recently completed by my colleagues and myself (Rossi, Berk, and Lenihan, 1980; Berk, Lenihan, and Rossi, 1980), mainly because some of the more interesting aspects of such work do not get much attention in the formal publications.

The policy origin of the Transitional Aid Research Project (TARP) experiments was a legislative directive to the Department of Labor to help ex-felons to attain productive employment. The Department had tried a variety of programs including skills training, special employment placement efforts, and small amounts of financial aid. Some hope resulted from a small-scale experiment (Lenihan, 1978) which appeared to show that modest payments simulating unemployment insurance benefits were effective in lowering rates of arrest for property crimes.

These promising findings were not convincing enough to call for a national program as the pilot experiment was small, it was conducted in only one jurisdiction, and the payments were not administered by an established government agency. An experiment, the Department reasoned, conducted by a dedicated set of social science researchers, was not the same thing as a program that would be run by state or federal civil servants.

The TARP experiments, conducted with persons released in 1976 from the state prisons of Georgia and Texas, were designed to test whether or not a modest extension of unemployment insurance benefits to released prisoners would aid such persons to make the transition to civilian life without reverting to crime. Although aimed at reducing recidivism, the TARP experiments were far from being either revolutionary or even a very radical departure from existing social policy. The TARP intervention did nothing about the prison systems of the two states involved, nor did it address in a very direct way the causes of crime. Furthermore, TARP was scarcely responsive to several important theoretical systems current in criminology, especially the conflict and labelling perspectives. It was concerned with the current policy space of policy makers: an extension of unemployment insurance coverage to persons released from state prisons seemed to Department of Labor officials to be a policy change likely to achieve enough support in Congress to have a good chance to be enacted into policy, were it possible to show that such an extension could help released prisoners and have substantial equity benefits.

Yet the TARP experiments were not raw empiricism. A very respectable, quite traditional theoretical strain in criminology links together poverty and crime and regards criminal activities as attractive alternative occupations to poorly skilled and inexperienced poor youths. Abundant cross-sectional data link together poverty conditions and crime rates, but such correlations are hardly proof of causal relations. While no one with any shred of morality would ever design an experiment that used poverty as a treatment, it is quite acceptable to most moral sensibilities to provide the exactly opposite treatment, to make persons better off economically. The TARP experiments, then, may be regarded as part of the crime and poverty theoretical tradition providing some experimental evidence on a significant theoretical issue.

Technically, the TARP experiments were very challenging. First of all, it was necessary to design a research project that could produce results that would have high internal validity. A randomized controlled experiment was, therefore, decided upon as the study design. Persons released over a six-month period from the Georgia and Texas prisons were randomly assigned either to: (1) one of three treatment groups that were offered eligibility for at least 13 weeks of unemployment insurance benefits at the minimum benefit levels prevalent in the two states—$63 and $70 per week, respectively, in Georgia and Texas; or (2) an experimental group that was offered employment counseling through the state employment security agency; or (3) one of two controlled groups. Approximately 2,000 released prisoners in each of the two states participated in the experiment. About half of the participating prisoners were followed for a year beyond release with periodic personal interviews asking about their post-release employment experiences and tracking other important life events. In addition, all participating ex-prisoners were tracked through the computerized state arrest criminal justice files which recorded arrests and convictions and through unemployment insurance records which contained quarterly reports on earnings that were subject to the taxes on employers that supported the unemployment benefit systems. Following this extraordinarily transient group, over time, was a considerable tour de force of field work: the high response rates of over 85% for each of three follow-up interviews is an accomplishment that is a considerable tribute to the local interviewing crews and the overall orchestration by Kenneth Lenihan.

The resulting data constitute a considerable body of information on the post-release experiences of ex-felons, better and more detailed than any other data set, a considerable mine of information about the lives of members of this segment of the American underclass. These data are now in the public domain and can be used by any social scientist for a variety of purposes.

As often happens, the policy implications of the experiments' findings are a mixture of good and bad news. First of all, when looked at in the traditional analysis of variance perspective, the treatments clearly failed as administered. Experimental groups were neither more nor less likely to be rearrested in the postrelease year. Hence, it is clear that an extension of unemployment benefits within the existing unemployment benefit system will not avert arrests and the crimes that such arrests represent. Additional bad news was that the benefits had rather strong work disincentive effects, with those treatment groups receiving payments working considerably less, a perverse outcome for a treatment that was supposed to aid the ex-prisoners into normal civilian life.

In order to obtain good news from the experimental results, it was necessary to reexamine the theoretical foundations of the experiment and to depart from the traditional analysis of variance perspective. The reexamination of theoretical foundations led us to consider the recently revived economic interpretation of crime and to draw upon sociological thinking on occupations and work. The resulting theoretical model explained both the seeming lack of an effect of payments on arrests and the work disincentive effects of the payments. Briefly, the payment lowered arrests by lowering the incentives to criminal activities but increased arrests by lowering employment. These two effects cancel out each other, leaving no differences between experimentals and controls in rearrest rates but considerable differences in employment experiences. Modelling this process through simultaneous equation procedures produced results that were consonant with the theoretical model and which were similar in both Georgia and Texas. In addition we were able to show that the payments had the positive effect of enhancing wage rates when employed for persons in the experimental groups that were eligible for payments—the financial cushion supplied by payments allowed some of the leisure to find better employment.

The extended results obtained by broadening the theoretical bases of the experiments and departing from the analysis of variance technique has already generated controversy. We believe that the results justify attempting to set up a benefit system—the "severance pay model," as we have called it—that does not have a severe work disincentive built into it as does the unemployment benefit system that provides benefits only when one is unemployed. Our critics point to the analysis of variance results and claim that the more complicated and, hence, more delicate simultaneous equation modelling is speculative at best. My colleagues and I are sure to be under attack on substantive and technical grounds as soon as the monograph comes under review.

The point of mentioning the controversy that exists now (and that will most likely escalate) is not to elicit sympathy for the "pure scientists" under attack. Rather, it is to illustrate that politics and methodology are not separable. The failure of the policy as tested led the liberal-minded investigators to doubt that the analysis of variance results were the only and best description of the outcome of the experiments and to analyze the data further with more sophisticated approaches. More conservative minds, who might believe that criminals are not to be coddled because they are incorrigible, distrust the results of a more sophisticated approach and prefer to rest—content with the more robust analysis of variance.

The interpenetration of politics and methodology has both positive and negative effects. On the negative side, it can mean that policy-related research is rarely regarded as definitive. On the positive side, it certainly sharpens one's sense of responsibility concerning method, enhancing the care with which data are treated and the level of skill employed.

Has the experiment affected social policy? So far, not very much. When I made a presentation of the findings to the Secretary of Labor last year, I found that Secretary Marshall was quite intrigued with the ideas and was inclined to start policy changes; but subsequent federal budget difficulties have placed any such changes on the shelf.

The TARP experiments have all of the characteristics I outlined earlier. First, on the positive side, the problem of the relationship between poverty and crime is theoretically relevant, with the experimental results providing important new data illuminating the relationship. Hence, we hope that it makes a contribution to basic sociology and, especially, to theories of criminality. Second, the research was technically challenging, with sufficient resources made available to employ a powerful (and expensive) research design and to afford extensive data processing and advanced analytical methods. Third, the policy being tested was a "good" one—that is, if enacted it would provide benefits to persons who were in need and deprive no one else of very much. Indeed, because potential savings through averted arrests can be considerably greater than the costs of payments, taxpayer dollars can be saved.

On the negative side, first, one might view the experiment as tinkering with a system that needs major overhauling. The TARP policy was scarcely radical or very innovative. Second, controversy exists and is bound to increase over whether or not the experiments actually showed the results that we believe they showed. Finally, the experiments did not immediately affect social policy. The changes (in the way in which we treat ex-prisoners) that may result from the experiment have been postponed to the future—how far in the future, one may only speculate, given the possible changes in our federal government that this year's election might produce.

What is the balance between positive and negative? Given the slowness of the process by which new research findings are assimilated into the body of sociology, it is clearly too early to tell. Interestingly enough, the negative is experienced immediately, but the positive outcomes will take place, if at all, over the next decade. My colleagues and I have great hopes that, eventually, the score will show a decided positive balance.

Opportunities in Applied Social Research Today

Applied social research may or may not be as attractive as I have described it, but if there are no opportunities for participation in such activities, then that message may be enlightening—but irrelevant—to our discipline. Such is decidedly not the case, however: applied social research must be described as having been, during the last two decades, one of the growth sectors in our economy. Estimates (Abt, 1980) of the amounts spent in the federal budgets of the last few years on applied social research, in one form or another, vary from a high of two billion to a low of about one billion. The amount spent on the evaluation of educational programs alone was estimated to be more than 100 million in 1976. Whatever estimate one accepts, the numbers indicate that applied social research is big, strong, and flourishing—especially when compared to the support of basic social research program funds, which amount to only several hundred million for all the social sciences combined. In addition, private foundations also provide support, although on a smaller scale.

Note that these funds count only the federal budget allocations. State and local governments also support applied social research, perhaps not to the same extent but adding at least several hundred million more.

With all these funds going for applied social research, one might predict that sociology and sociologists would be wallowing in prosperity. Such appears to be far from the current state of our discipline. While we are not on the threshold of destitution and widespread unemployment, it does not appear that sociologists generally have participated fully in the last two decades of growth in applied social research. There are a variety of reasons for our failure to participate.

First of all, applied social research is certainly not the monopoly of sociology. Economics, psychology, political science, education, geography, anthropology, and such hybrid fields as business, communication, social work, and operations research are all fields that can and do participate in applied social research. Indeed, my best estimate is that economists, psychologists, and educational researchers are more deeply involved in applied social research than any other field. Of course, the three leaders in applied social research are bigger fields than sociology and, hence, such leadership reflects in part the fact that there are simply many more psychologists, educators, and economists than sociologists. But it also reflects the fact that, within those fields, applied work is accorded higher regard than in sociology. Sociology has been primarily an academic field, with far fewer sociologists employed outside the groves of academe, compared to the profile of economists and psychologists.

Second, much of the funds available for applied social research does not go to universities but to nonacademic organizations. Within the last decade, new organizations have appeared on the scene to provide the applied social research that was demanded by the existence of research funds. Older, nonacademic research organizations have also responded by increasing their staffs. Research organizations loosely connected with universities, such as NORC and Michigan's ISR, have expanded as well. Some of the larger research firms now dwarf university social science divisions. For example, Abt Associates, Inc., located in Cambridge, employs more social science Ph.D.'s on its staff than any of the universities in the Boston area. The Rand Corporation in Santa Monica has enough social scientists on its staff to offer a Ph.D. program in the social sciences.

The rapid increase in effective demand for applied social research has not been without accompanying problems. First of all, it appears that legislators often imposed impossible research demands—yet, at the same time, offered funds to do those impossible tasks, a situation that is a structured strain toward hypocrisy, and fraud on the part of suppliers. Literally scores of "beltway bandit" firms were started to bid on the offered contracts, often to accomplish tasks that could be done or completed within the allotted time or budget or with existing research technology. Second, the demand for applied social researchers exceeded the available supply, with the result that there were many persons who became social researchers by fiat. A serious negative consequence of the rapid growth in applied social research was that the quality of much of such research was exceedingly poor—especially in the earliest part of the growth period and especially on the state and local level. Fortunately, there is an apparent secular trend toward increased quality accompanied by a high failure rate among the "beltway bandits." The low quality of some of this research, however, has not helped to raise the status of applied social research among the academic disciplines.

Not all of the quality problems of applied social research have been solved. There are still many applied research projects that are ill-conceived, sloppily executed, and presented in a misleading fashion. Yet the best of applied social research is as good as the best social science going. Furthermore, the average quality is rising as quality standards diffuse more widely and as the critical process described earlier takes hold.

It is especially striking that the research-oriented universities and social science departments have not participated very much in the burgeoning market for applied social research. One of the major reasons has just been alluded to: often, the research tasks were impossible to accomplish and inadequately funded. But there are also additional reasons. First, applied social research is not very high on the academic totem pole of prestige. Second, even when the research tasks are attractive and of intrinsic interest, academicians find it difficult to respond quickly to the research procurement process and to mount the often-extensive, large-scale research projects that are called for. Whatever the reasons, the concentration of applied social research activities outside the university walls has meant that sociology as primarily an academic discipline has not been reached by this new prosperity.

Third, applied social research demands skills that not all sociologists have received through training or through practice. By and large, applied social research is quantitative research and I would venture that the level of relevant skills achieved on the average by sociologists is considerably below that of the social science fields that have been more successful in applied work. In addition, applied work requires an attentiveness to policy-related structural features of our society. For example, the TARP experiments are concerned not with altering the etiological conditions of crime in our society but with slight, inexpensive, and politically expedient alterations in our social services system that might avert a very small proportion of all crimes.

Whatever the reasons for our discipline's lack of participation in applied social research, it is clear that we are missing out on some important opportunities. Primary among these missed opportunities are those that relate to the intellectual health of our discipline. Applied social research, as I have tried to argue earlier, here, provides important opportunities to learn more about how society works for building theory and for strengthening our base of empirical knowledge.

There are also organizational reasons for building a stronger level of participation in applied social research. Academic employment for sociologists at present—and even more so in the future—is drying up. We can no longer afford to run undergraduate curricula that lead to no specific vocational opportunities for graduates. Few departments in the country are experiencing any increases in undergraduate enrollment and in majors. We appear to be losing out to fields in which there are clear employment opportunities beyond graduation. I suggest that junior-level applied research opportunity is one such vocational goal that we could emphasize in our teaching and training programs.

Applied social research is even more important for graduate-level training in our discipline. There are jobs out there in the applied social research "industry" that properly trained new sociology Ph.D.'s could enter.

In order to take greater advantage of these occupational opportunities for our undergraduate majors and those who earn graduate degrees, it is necessary for the discipline to build linkages to applied social research as an institutionalized activity. This means that academic sociologists will have to participate more in applied work. We have to learn how to compete successfully for the funds that are available, learn how to undertake the more complicated and extensive research tasks that are involved. This last point may mean that we have to build research organizations within universities or loosely connected with them that can efficiently and skillfully carry out the research tasks involved. Building such organizations will mean that academicians will have the experience to understand properly the research tasks involved and will be able to provide the apprenticeship-like hands-on experiences for undergraduate majors and graduate students that can make academicians attractive as researchers. We will also have to revamp our undergraduate and graduate curricula to reflect a greater emphasis on quantitative research and on policy-oriented research. Note that I am not suggesting that sociology become a monolithic discipline as far as research methods are concerned. All I am advocating is greater emphasis, especially at the undergraduate level.

Of course, all the changes suggested above imply a greater recognition to be given to applied work as crucial to the health of our discipline. That means that we should not lift our eyebrows when our better graduate students take nonacademic research positions, conveying the notion that by so doing they have left the company of the elect. It means that we evaluate applied social research as research and not automatically deduct points because it is applied. It also means that those of us who do both basic and applied work should be as proud of the latter as of the former. Applied social researchers should come out of the closet!

There are other institutional changes that would also be helpful. Our professional association currently has an academic bias that manifests itself in a variety of ways: our employment bulletin lists few nonacademic positions, and the editors of our professional journals are reluctant to consider articles that are clearly applied research. The American Sociological Association should be taking the lead in helping to bridge the distance between our discipline and the intellectual and employment opportunities in applied social research.

Sociology has deep roots in humanity's desire to understand and control the turmoil of social change and in its striving for ways to lessen the toll of humankind. It would be to deny our heritage to become more and more turned inward to an increasingly precious academic discipline. For the sake of our intellectual growth and our disciplinary strength, we need to provide a more respectable place for applied work, a move that will surely redound to our benefit in excitement, theoretical progress, and a renewed sense of the relevance of our work to the world around us.

MANUSCRIPTS FOR THE *ASA ROSE SOCIOLOGY SERIES*

Manuscripts (100 to 300 typed pages) are solicited for publication in the *ASA Arnold and Caroline Rose Monograph Series*. The Series welcomes a variety of types of sociological work—qualitative or quantitative empirical studies, and theoretical or methodological treatises. An author should submit three copies of a manuscript for consideration to the Series Editor, Professor Suzanne Keller, Department of Sociology, Princeton University, Princeton, NJ 08540.

SOCIAL PROCESS AND HIERARCHY FORMATION IN SMALL GROUPS: A COMPARATIVE PERSPECTIVE*

IVAN D. CHASE
State University of New York at Stony Brook

American Sociological Review 1980, Vol. 45 (December):905–924

The author investigates the theory, methods, and findings of animal behaviorists and social scientists studying dominance hierarchies in small groups. In both disciplines: (1) the literature argues that the explanations of hierarchy structure are based upon differences in individual characteristics among group members; (2) although critical examination reveals that these explanations require stringent conditions to account for commonly occurring kinds of hierarchies in humans and animals, the available data indicate such conditions are not met; and (3) the hierarchy-formation process has not been adequately studied. In an attempt to alleviate the current problems in hierarchy research, I present the results of a particular animal study and develop a general explanation as to how hierarchy structures arise. This approach applies to both humans and animals and serves as a model of how the cumulative patterns of interactions among individuals produce group social structures.

Despite great differences in social behavior in many human and animal groups, their dominance hierarchies are remarkably similar (see Brown, 1975; and Wilson, 1975, for general background on dominance hierarchies). Why should species so diverse as animals are from one another, and as all the animals are from humans, form dominance hierarchies so similar in structure? And, even more basically, how are we to study and explain the formation of dominance structures in small groups of men and animals? The goal, here, is to make a start toward answering these questions by developing a new approach to the study of hierarchy structures. This approach explains how hierarchies emerge from the interaction among group members rather than being generated by differences among those individuals. It treats hierarchy formation as a developmental process in which the outcomes of previous interactions influence the course of successive ones, and it indicates how patterns of interaction fit together to form the kinds of dominance hierarchies commonly observed.

This paper is in five parts: (1) a summary of the data collected on dominance hierarchies and the methods used to gather those data in both the animal behavior and the human social sciences literature; (2) a critical evaluation of the theories that have been proposed to explain hierarchy structures in both disciplines; (3) a presentation of the results of a study of hierarchy formation in an animal group; (4) a new approach to the theory of hierarchy formation; and (5) an evaluation of the new approach as well as a discussion of the implications of the results for continuing research.

An earlier version of this paper was presented at the 1978 Annual Meeting of the American Sociological Association in San Francisco. Many colleagues have commented on and contributed to this paper, and I am grateful for their support. In particular, I would like to thank Jack Hailman for his incisive discussion and general encouragement. Jeffrey Baylis, Ann Becker, Shelly Cohen, Ken Feldman, Mark Granovetter, Gene Weinstein, Bill Wimsatt, and one anonymous reviewer provided many helpful criticisms of earlier versions of the paper, and I am most appreciative of their efforts. I would like to thank Gordon Stephenson for help with the SSR System, Sara Edwards and Nancy Raffetto for assistance with data collection, and Erica Jen for computer wizardry and assistance with techniques of analysis. Veronica Abjornson, Carole Roland, and Rosemarie Sciales speedily turned rough draft into final copy, and Mary Ann Huntington drew the figures. Part of the research reported here was conducted under a grant to the author from the Harry Frank Guggenheim Foundation, and the observational data were gathered in the Department of Zoology, University of Wisconsin-Madison. The support of both the Foundation and the Department are gratefully acknowledged.

HIERARCHY STRUCTURES IN ANIMAL AND HUMAN GROUPS

The Animal Behavior Approach

One of the distinguishing features of the animal behavior or ethological tradition is the emphasis on behavioral observation and the use of ethograms (or catalogs of behavior) developed for each kind of animal or human group studied. In a typical ethological study, a group is observed for a period of time sufficiently long to discover the direction of dominance relationships among all possible pairs in the group. The direction of a dominance relationship in a pair is typically determined by asymmetries in the agonistic (a category including both aggressive and submissive behaviors) behavior of the individuals toward one another. For example, the individual who delivers all or the majority of aggressive acts in a pair is considered dominant, and the individual who receives the acts or initiates most of the submissive gestures is considered subordinate. The pattern of the relationships in a group is frequently represented in a "dominance matrix." A dominance matrix has either a "0" or a "1" in all off-diagonal cells: a "1" in the i, j cell indicates that individual i dominates individual j and a "0" indicates that j dominates i.

All the dominance relationships in a group, taken together, form the hierarchy structure. Theoretically, hierarchy structures can vary from linear, at one extreme, to the other extreme in which each individual in the group dominates an equal number of other individuals. In a linear hierarchy there is an individual A who dominates all others, an individual B who dominates all but A, and so forth, down to the last individual who dominates no one. An example of a dominance matrix for a linear hierarchy with five individuals is given in Table 1, and a matrix for a hierarchy as far away from linearity as possible—in which each animal dominates an equal number of animals—is given in Table 2.

Table 1. Dominance Matrix Showing a Linear Hierarchy

Dominant Animal	Dominated Animal					Number Dominated
	A	B	C	D	E	
A	—	1	1	1	1	4
B	0	—	1	1	1	3
C	0	0	—	1	1	2
D	0	0	0	—	1	1
E	0	0	0	0	—	0

A surprisingly uniform finding by ethologists is that hierarchies in small groups (less than about ten members) are frequently and perhaps predominantly linear or near-linear. This finding is stable across many individual researchers' work and across an extremely broad range of animal species from insects to primates. For example, linear and near-linear hierarchies have been found among certain kinds of wasps and bumble bees (Wilson, 1971); various birds—such as chickens (Guhl, 1975), chaffinches (Marler, 1955), and red crossbills (Tordoff, 1954); domestic mammals—such as cows (Schein and Fohrman, 1955) and ponies (Tyler, 1972); wild mammals—such as coyotes (Bekoff, 1976) and buffaloes (McHugh, 1975); and primates in the wild and in captivity—including rhesus monkeys (Sade, 1967), baboons (Hausfater, 1975), and vervets (Struhsaker, 1967). In the primates, hierarchies can become more complex through both the formation of coalitions and what is known as dependent rank (Jolly, 1972). In dependent rank, a particular individual (animal) is able to achieve dominance over another animal in the presence of a third animal (frequently its mother or consort) but not able to do so if the third animal is not present. However, even in those groups where coalitions and dependent rank are found, there is often a linear or near-linear

Table 2. Dominance Matrix Showing a Hierarchy in Which Each Animal Dominates an Equal Number of Other Animals

Dominant Animal	Dominated Animal					Number Dominated
	A	B	C	D	E	
A	—	1	1	0	0	2
B	0	—	1	1	0	2
C	0	0	—	1	1	2
D	1	0	0	—	1	2
E	1	1	0	0	—	2

hierarchy if relationships are examined between pairs when a coalition partner or third party conferring dependent rank is not present.

Researchers in the ethological tradition who have studied human groups have frequently focused on hierarchical relationships; many of these studies have been on preschool children (McGrew, 1972; Missakian, 1976; Strayer and Strayer, 1976), but adolescent groups have also been examined (Savin-Williams, 1977; 1979; 1980). In addition to using nonverbal, behavioral measures of dominance, as in the animal studies, some studies have also employed verbal indices of dominance—for example, if A gives an order to B and B obeys, then A is rated as dominant to B (Savin-Williams, 1977; 1979; 1980). As in the animal studies, findings indicate that human hierarchies are frequently linear or near-linear (Missakian, 1976; Savin-Williams, 1977; 1979; 1980). In those studies where data have been collected for some but not all possible pairwise interactions, the data indicate that only a few interactions deviate from those expected in a linear hierarchy (McGrew, 1972; Strayer and Strayer, 1976).

Another uniform trend is that most studies by ethologists have been static. That is, in the great majority, studies have described a given hierarchy structure at some particular time rather than either explaining how that hierarchy structure was established or examining the processes by which members of the group changed rank over time.

The Human Social Science Approach

The research of sociologists and social psychologists, like that of ethologists, has provided, for the most part, static descriptions of social structure in small groups. There are a few notable exceptions (such as Newcomb's [1961] work) but these tend to utilize self-reported preference (friendship) data rather than observational data on asymmetric relationships. These static descriptions indicate a strong hierarchical component in the social structure of a broad spectrum of human small groups. Three areas of research are of relevance here: the study of human small groups in laboratory settings, the study of these groups in "natural" situations, and the analysis of sociometric data.

When groups of unacquainted individuals are assembled in laboratory settings, a differentiation of members quickly emerges along such dimensions as frequency of originating and receiving various kinds of behavioral acts and ratings of leadership and likeability by fellow group members (see Collins and Raven, 1969; Gibb, 1969; and Hare, 1976, for comprehensive reviews). Some members show behavioral profiles that give them relatively high control over the actions of their fellows and over group activities in general, while other members exert relatively little influence on either group activities or their colleagues (e.g., see Bales and Slater, 1955, and the reviews cited above). Researchers using the status expectation paradigm have shown that external status characteristics—such as social class, race, and gender—influence the distribution of participation and prestige in these groups (see Berger et al., 1972, for a general statement of the paradigm and Fennell et al., 1978, for a provocative discussion of differences in male and female groups).

Although ethologists and laboratory small-groups researchers frequently collect the same kind of data—individual A directs an act of type X to individual B—their analyses of the data are different. As mentioned above, ethologists look at the hierarchy structures produced by all possible pairwise relationships among group members. Laboratory small-groups researchers, however, tend to concentrate on rank measures—the comparison of individuals in terms of total interaction rates or group preference scores. Bales et al. (1951) is a partial exception in that they give pairwise interaction frequencies for 18 aggregated sessions of six-man groups.

Studies in natural settings—such as those by Blau (1955) of a bureaucratic agency, Hanfmann (1935) of kindergarten children, Homans (1950) of an industrial work group, and Whyte (1955) of gangs—provide further confirmation of the hierarchical structure of human small groups. These studies all find clearly differentiated status rank systems based upon both the behavioral actions and sentiments of group members. Although most of these studies, like the laboratory small-groups studies, do not provide data on all possible pairwise relationships in their groups, the work of Hanfmann (1935) is an exception. Her data indicate the presence of a near-linear hierarchy in kindergarten children, comparable to those reported by ethologists for other human and animal groups. (See Mazur, 1973, for a pioneering comparison of hierarchies in humans and animals; his approach and conclusions, however, differ from those presented here.)

The studies of sociometric data by Davis (1970), Hallinan (1974), and Holland and Leinhardt (1970; 1971; 1972) provide some of the most sophisticated descriptions available of social structure in small human groups. Although one might expect preference choices to yield structures considerably different from those produced by dominance relationships, there are in fact considerable similarities. These researchers have discovered (with high consistency across studies and samples) that there is a strong trend toward transitivity in the preference relations of group members (for example, if A chooses B as a friend and B chooses C, than A will choose C also). As will be explained in greater detail, there is a similar strong trend toward transitivity in the dominance relationships of human and animal groups. In a linear hierarchy all possible triads have transitive dominance relationships; and, in a near-linear hierarchy almost all the possible triads have transitive relationships. Davis (1970:850) suggests that, with more refined data where the stronger preference relation for every pair in a group could be determined, "sociometric data would tend to fit the model of a transitive tournament." A transitive tournament is another term for a linear hierarchy and, if Davis's suggestion is correct, then social structures produced properly refined preference relationships, and dominance relationships would be identical.

THEORIES PROPOSED FOR THE EXPLANATION OF HIERARCHY STRUCTURES

I will now examine theories proposed—explicitly and implicitly—in both the animal behavior and human social sciences literature, to explain the formation of hierarchy structures. This examination is based upon previous research by the author (Chase, 1974). The procedure used in that study was this: various theories of hierarchy structure were expressed in their basic (core) form, and that core form was converted into a mathematical model, a simple mathematical expression of what the core form implied. Then the stringency of the conditions needed by each mathematical model to predict the empirically common linear and near-linear hierarchies was examined and the available data inspected, to determine if the conditions were met.

The two mathematical models that proved to encompass most of the explanations of hierarchies were a correlational model and a pairwise interaction model. For example: explanations that are basically correlational models are those that indicate that individuals' positions in a hierarchy are determined by their physical attributes, their genetic endowment, their hormonal state, their past social performance, their personality traits, the social labels that they have been given, or any composite of these factors. In order to account for linear and near-linear hierarchies, correlations between ranks in a hierarchy and their scores on any of the above-mentioned variables or composites would have to be .9 or greater (Chase, 1974). This theoretical result holds for linear and near-linear hierarchies no matter what species of animal, including humans, are involved and no matter what variables or composite of variables are used to predict rank in a hierarchy. This is a high correlation coefficient, indeed, and one which indicates that any correlational explanation must fulfill a stringent mathematical condition.

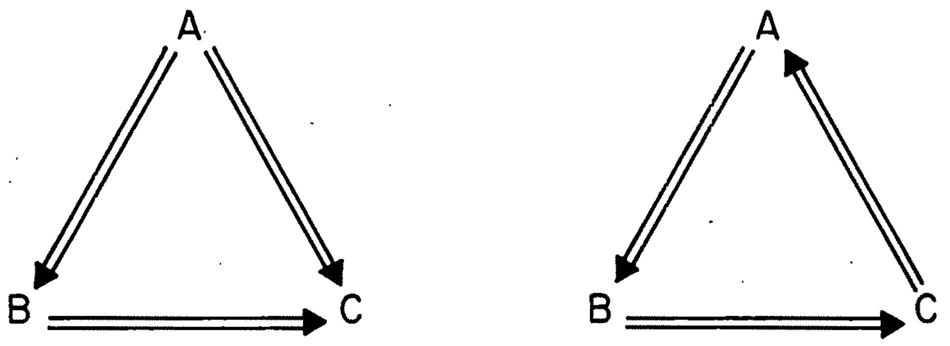
An examination of the literature indicates that correlations of .9 or higher are not usually found between a factor predicting dominance and rank in a hierarchy. Some of the best correlational data available are for animals and, specifically, for the premier animal of dominance studies—the chicken. Correlations vary in size for different investigations and, in studies that examined the association between an individual's aggressiveness—as indicated by its success in fights with other animals, and its place in a hierarchy—correlations ranged from about .4 to .8 (Chase, 1974). These correlations, then, were not as high as the target value of .9, although some were near.

Explanations of hierarchies that are pairwise interaction models in their canonical form are, for example, differences in fighting ability for animals, theories dealing with the interaction of personality types for humans, and exchange theories for humans. In this model it is assumed that each member of a group has a pairwise contest with each other member, that the winner of a contest dominates the loser in the group hierarchy, and that an individual has a particular probability of success in each contest. This model requires that there must be one individual with a .95 probability of dominating each other individual, a second individual with a .95 probability of beating every one but the first individual, and so forth down to the last individual who has only a .05 probability of beating any other individual (Chase, 1974). These results hold, regardless of the species of animal and regardless of what factors are assumed to explain success in pairwise interactions. As in the correlational model, these results indicate that stringent mathematical conditions must be fulfilled with the pairwise interaction model. Again, it has been found that data which best determined if these conditions were met were from animals, specifically chickens, and that the required conditions were *not* fulfilled (Chase, 1974).

It is not that correlational and pairwise encounter theories and measurements give us no useful information about the success of individuals in dominance interactions or the places of individuals in hierarchies; they do, indeed; but the kind of information they give us is not sufficient to account for a group level social structure, the overall hierarchy found in a group. Although individuals in a group may differ, it appears that the differences are not strong enough to explain empirically common dominance structures (see Hallinan, 1974, for a similar argument concerning individual differences and sociometric structures).

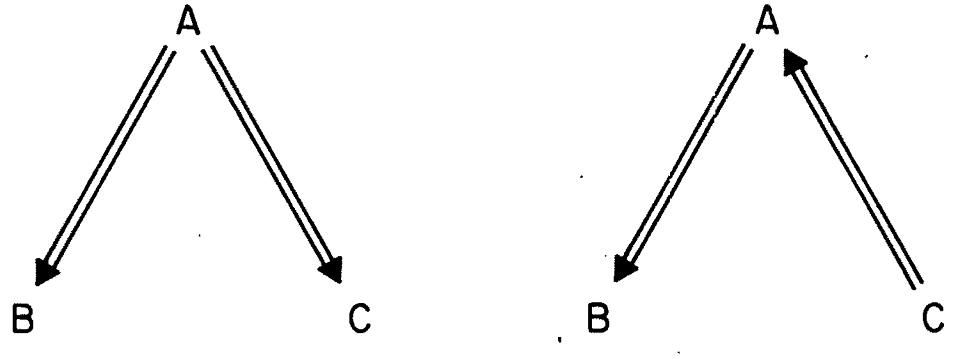
TRIADS AND THE FORMATION OF HIERARCHIES

If many of the currently accepted theories of hierarchies and dominance relations are not adequate, then what might explain the presence of linear and near-linear hierarchies so frequently found in human and animal groups? As discussed above, theories that attempt to explain hierarchy structure by correlations (or the characteristics of single individuals) and theories that use pairwise interactions (or the characteristics of pairs of individuals) appear to be inadequate. As Simmel realized long ago, three is a very important number in sociology, and I shall show that the structure of interaction in triads is very important for explaining the formation of linear and near-linear hierarchies. In order to understand the importance of triadic interaction, one must be aware of a simple mathematical fact: in a linear hierarchy all possible triads have transitive dominance relationships, and if a hierarchy is not linear it contains at least one triad with intransitive dominance relationships—and the fewer the intransitive triads, the closer the hierarchy to linearity. In a triad with transitive dominance relationships, if individual A dominates B and B dominates C, then A also dominates C. So, A dominates the other two members, B dominates C, and C dominates no one. Figure 1A shows a triad with transitive dominance relationships. In a triad with intransitive dominance relationships, the three individuals cannot be arranged in rank order because each individual dominates one other individual. That is, A dominates, say, B; B dominates C; and C dominates, rather than is dominated by, A. Figure 1B shows



A. Transitive Triad B. Intransitive Triad

Figure 1. The Configuration of Dominance Relationships in a Transitive and an Intransitive Triad



A. B.

Figure 2. (A.) Final Configuration of Dominance Relationships in All Triads Having Two Extant Dominance Relationships at the End of the Observation Period. (B.) Initial Configuration of Dominance Relationships in Triad with One Reversal

a triad with intransitive relationships. In a linear hierarchy all individuals can be ranked uniquely from top to bottom by the number of group members they dominate, and, therefore, any three can be ranked with respect to one another and form a transitive triad (this can be seen, for example, by taking all possible subgroups of three in Table 1). In a hierarchy which is not linear, not all individuals are uniquely ranked by the number of group members they dominate—there is at least one tie and, therefore, at least one intransitive triad. Table 3 shows the dominance matrix for a group in which there is a tie in rank between A, B, and C and one intransitive triad involving A, B, and C.

Table 3. Dominance Matrix Showing a Hierarchy with One Intransitive Trait Involving A, B, and C

Dominant Animal	Dominated Animal					Number Dominated
	A	B	C	D	E	
A	—	1	0	1	1	3
B	0	—	1	1	1	3
C	1	0	—	1	1	3
D	0	0	0	—	1	1
E	0	0	0	0	—	0

Experimental Design and Data Collection

Could linear and near-linear hierarchies be so common because animals and humans use behavioral processes which favor the formation of transitive triads and discourage the formation of intransitive triads? (Cf. Davis, 1970; Feld, 1980; Hallinan, 1974; Holland and Leinhardt, 1970; 1971; 1972 for discussions of forces promoting transitivity in preference relationships.)

In order to answer this question, I designed an experiment to determine the actual extent of transitive dominance relationships in groups of three individuals and, if transitivity were common, to discover the behavioral processes by which transitive relationships were generated. The species of choice for this experiment was the chicken; hierarchies in chickens are often linear or near-linear as are hierarchies in more socially complex species such as primates and humans, but at the same time the behavior of chickens is simple enough so that it is more tractable to analysis. In addition, the most extensive dominance research on any species is on the chicken.

In this experiment, groups of three previously unacquainted chickens were placed in a neutral cage, and all aggressive actions among the individuals were recorded. Twenty-four triads were observed; each chicken took part in three triads, and each chicken in a group had been in the same number of triads previously. The data recorded consisted of the identity of the chicken initiating an aggressive action (the attacker), the identity of the chicken attacked (the receiver), the kind of aggressive action (peck, feather-pull, claw (scratch), or jump-on), and the real (clock) time at which each attack occurred. Each triad was observed for four hours to give a grand total of 96 hours of observation time. A combined total of 2,801 aggressive acts was recorded, and the resulting average rate of aggression was 29.2 acts per hour or 116.7 acts per triad.

An SSR Keyboard was used to record the data. The data output from the Keyboard was converted to an electronic signal recorded on audio tape with a standard tape recorder, and the resulting data tapes were transcribed by computer to produce hard copies of the data record and files for later analysis by computer (see Stephenson et al., 1975, and Stephenson, 1979, for a description of the SSR Keyboard and its capabilities). An excerpt from a data record is presented in Table 4.

The Extent of Transitivity in Triads

When groups of previously unacquainted chickens are assembled, there are usually interchanges of aggressive actions between individuals although, in some pairs, one animal immediately submits to the other animal without ever fighting back. After either a short or more protracted series of interchanges, the asymmetric pattern of aggressive acts seen in established hierarchies develops: the interchanges stop and all or almost all of the aggressive actions are performed by one member of a pair against the other. At this point, one can think of a "decision" having been reached: a dominance relationship has been formed with one animal being dominant and the other subordinate.

In order to determine when a dominance relationship had been formed and, thus, to discover the extent of transitivity in the experimental triads, two criteria were used. One animal was considered to be dominant over another if: (1) it delivered any three aggressive actions in a row (any combination of pecks, feather-pulls, jump-ons, or claws) against the other animal and (2) there was a 30-minute period, following the third aggressive act, during which the receiver of the aggression did not attack the initiator. The involvement of either member of the pair

Table 4. Data Excerpt

Act Number	Real Time	Time Interval	Aggressive Acts
0	09:30:25.1	—	Session Begins
1	09:31:01.8	36.7 sec.	3P1[a]
2	09:31:03.5	1.7	3P1

[b] "C" is the code for a claw (scratch).
[d] "J" is the code for a jump-on.

with the third member of a triad was not considered in these criteria and neither was the length of time necessary for the completion of the three acts. Once formed, a dominance relationship could be reversed if the subordinate animal fulfilled the criteria. While somewhat arbitrary, these criteria have support as a valid index of stable dominance relationships—of the 54 dominance relationships meeting the criteria in this study, only two were later reversed within the four-hour observation period (afterward, each chicken was returned to its home cage). The average time required to fulfill the criteria in the 52 initially formed relationships was 82.6 minutes, and only two relationships were established within less than 30 minutes before the end of an observation period. There was, then, a sufficient time period after the formation of most relationships for reversals to occur.

An examination of the configuration of relationships at the end of each observation period indicated that 1 triad had no dominance relationships, 17 had two, and 6 had all three possible relationships. The 17 triads with two dominance relationships all had the same configuration—one animal dominated each of the other two. If the two dominance relationships were determined randomly, this configuration would have a probability of .25 and would be expected to occur, by chance, about four times in 17. This configuration is shown in Figure 2A. It is important to note that this configuration guarantees a triad with transitive dominance relationships regardless of which subordinate later comes to dominate the other (preliminary analysis of data from several groups of four chickens each, observed for 12 hours, indicates that subordinate animals tend to form dominance relationships among themselves, in time). If B later dominates C, there is a transitive triad with A on top, B in the middle, and C on bottom. If C later dominates B, there is a transitive triad with A on top, C in the middle, and B on the bottom.

Similarly, the 6 triads with three dominance relationships all had the same configuration, a triad with transitive relationships as shown in Figure 1A. A transitive triad has a probability of .75 of occurring if relationships are determined randomly—and would be expected to occur between four and five times out of six. Taken together, these findings demonstrate a marked tendency toward transitivity in the experimental triads, and this finding corroborates those of the studies of human and animal groups reviewed earlier.

An examination of the two groups with reversals in previously formed dominance relationships gives additional support for the tendency toward transitivity. In one of these triads, animal A initially dominated B but was herself dominated by C (see Figure 2B). With this configuration an intransitive triad would have developed had B come to dominate C or a transitive triad if C had come to dominate B. In actual fact, A and C reversed their relationship, and this produced the configuration shown in Figure 2A which guaranteed a transitive triad. In the other triad, the initial configuration of relationships was intransitive, as shown in Figure 1B. By the end of the observation period, A and B reversed their dominance, with the triad having a transitive relationship shown in Figure 1A resulting.

Behavioral Processes Leading to Transitivity

I now present a data analysis that shows how the interaction process in triads helps to explain the tendency toward transitive dominance relationships. The first part of the analysis treats the long-term structure of the interaction process and the second part, the short-term structure.

1. Long-term Processes. This analysis of long-term processes includes the 17 triads with two relationships and the 6 with three relationships and excludes the 1 triad with no relationships. The analysis examines the effect of "winning" and "losing"—that is, the impact of either gaining dominance or becoming subordinate upon the further aggressive behavior of a chicken.

The analysis begins with the 16 triads in which only two dominance relationships were formed (no reversals) and 1 triad with three relationships in which one animal first became dominant over the other two and then one of the subordinates became dominant over the other. (All other triads will be examined later.) An inspection of the first dominance relationship formed in each of the 16 triads with two relationships reveals that there is one uniform pattern of behavior followed by each animal becoming dominant, and another pattern by each animal becoming subordinate. The rule of strategy followed by each subordinate is to withdraw almost totally from all subsequent aggressive activity—not only against the animal that has become its superior but also against the bystander animal. None of the sixteen animals becoming the first subordinate in these triads ever became dominant over the bystander, nor did any ever reverse its relationship with its superior. In addition, the rate of aggressive activity of these animals dropped to almost zero after they received the third attack from the chicken to which they became subordinate; their average rate of aggressive activity before the third attack was 15.8 acts/hr. and after this attack it was 0.2 acts/hr. (significant at the $p < .02$ level, Wilcoxon signed rank test). On the other hand, each chicken winning the first dominance encounter went on to be aggressive toward the bystander and to gain dominance over her.

There is a slight variation on these rules found in the single triad in which one chicken first became dominant over the two others and then one of the subordinates became dominant over the other. In this triad, the strategy of the initially dominant chicken was the same as in the preceding paragraph; she went on to attack—and win dominance over—the bystander. The loser of the initial dominance encounter, however, showed a small variation in strategy. After the third attack by the animal to which she became initially subordinate, she initiated no aggressive acts at all for 115 minutes; then she began to attack the bystander, later winning dominance over her.

The next part of the analysis concentrates on 4 triads in which three dominance relationships were formed. Figure 3 shows the order of formation of dominance relationships in these triads. In these triads the chicken losing the first dominance encounter lost a second dominance encounter with the bystander, and, then, the animal who won the first dominance contest engaged the bystander (who had won the second dominance contest in the group) in a contest to determine dominance. The strategy of the initial subordinate was the same as in the groups above: she decreased her aggressive activity, and she did not become dominant over the bystander or reverse her relationship with her initial superior. The strategy taken by the winners in these triads is similar to that of the winners in the groups above; winners here directed aggressive acts toward the animal not yet dominated—that is, the winner of the initial contest and of the second contest (the bystander) battled for dominance. Initial dominators won over bystanders in three out of four cases, but no matter which won, a transitive triad was guaranteed by the initial configuration of relationships (A and C both dominated B).

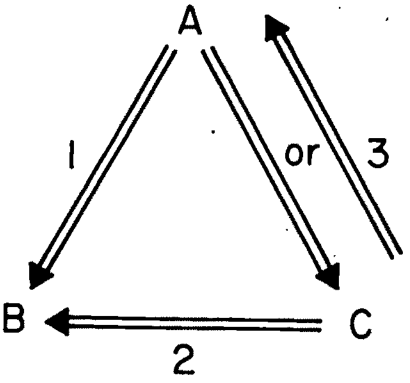

Figure 3. Configuration of Dominance Relationships in the Transitive Triad Resulting When the Initial Dominant and Bystander Engage in a Dominance Contest After Each Has Won over the Initial Subordinate

The final collection of groups to be examined are the 2 triads in which an initially formed dominance relationship was later reversed. There were two extant dominance relationships at the end of the observation period in one of these triads and three relationships in the other. Figures 4A and 4B show the order of formation of relationships in these triads. In the group ending with two relationships, the

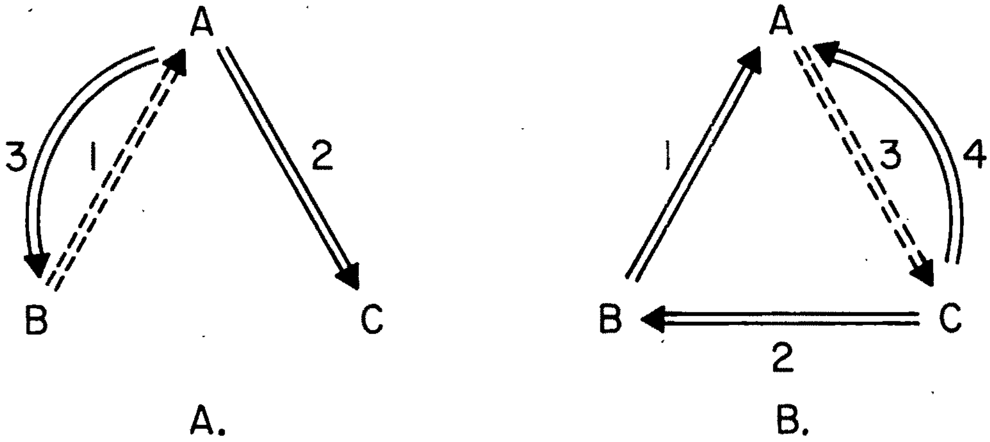

Figure 4. The Order of Formation of Dominance Relationships in the Two Triads with Reversals (Dominance Relationships Later Reversed Are Indicated by Dashed Lines)

initial subordinate became dominant over the bystander, and then reversed her relationship with the initially dominant chicken. The initial subordinate in this group did not follow the same strategy as losers of initial contests in the groups discussed above; she did not withdraw from aggressive activity. The winner of the initial contest also violated the usual strategy—she did not engage the bystander in a dominance contest. However, after the loser of the initial encounter became dominant over the bystander, she followed the usual winner's strategy of engaging the animal not yet dominated, and in this case the engagement resulted in a reversal.

In the group ending with three relationships, the initially dominant chicken was later dominated by the bystander, and the bystander was, in turn, dominated by the initially subordinate chicken. These relationships resulted in an intransitive triad until the bystander reversed her relationship with the initial subordinate to form a transitive triad lasting until the end of the observation period (see Figure 4B). In this triad, the bystander came to dominate the initial dominant rather than the initial subordinate as in the other triads in which the bystander forms a dominance relationship, the initially dominant chicken lost to the bystander (a rare event, it seems—based upon the data collected for this study, anyway), and the initial subordinate withdrew from aggressive activity only briefly and then won a dominance encounter against the bystander. At this point, each member of the triad was both a winner and a loser vis-à-vis the other triad members, and one of them (the bystander) followed a usual winner's strategy of engaging the animal not yet dominated; that engagement then resulted in a reversal and the formation of a triad with transitive relationships.

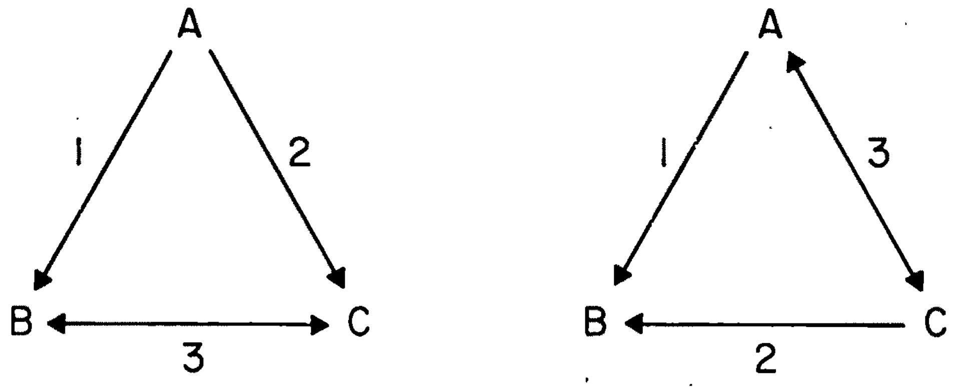
The usual strategies of both winners and losers (discovered here) help to explain the high proportion of triads with transitive relationships and triads guaranteed to be transitive. First, the withdrawal strategy of the initial subordinate guarantees that she will not be the dominant animal in the next relationship formed. Her withdrawal, therefore, obviates the possibility of a configuration of the type in which A dominates B and B dominates C. Without a configuration of this type there is no possibility for the formation of a triad with intransitive relationships (with a configuration of this type a transitive triad could still result, depending upon the direction of the third relationship). Second, the strategy of the initial winner—to engage the animal not yet dominated—guarantees the formation of at least two relationships in a triad. There are three subcases to be examined here. In the first subcase, the bystander does not win a dominance contest against either the initial subordinate or the initial dominant, and the initial dominant wins against the bystander. This results in a triad with a dominance configuration of the type in which A dominates both C and B, and such a triad is guaranteed to have transitive relationships, regardless of which of the subordinates later comes to dominate the other. In the second subcase, the bystander wins a dominance contest against the initial subordinate, and then both the initial dominant and the bystander follow the winner's strategy and engage in a dominance contest with each other. No matter which wins, a transitive triad will result; the transitivity is guaranteed by the configuration formed by the first two dominance relationships—A and C both dominate B. The third subcase is a residual collection in which, for example, a loser violates the usual strategy and wins against the bystander or a bystander wins against the original dominant in forming the second dominance relationship in a triad. In these situations the eventual employment of the usual winner's strategy of engaging the animal not yet dominated can result in a reversal and a transitive configuration or a configuration which guarantees transitivity (see the analysis of the triads with reversals, for examples).

2. *Short-term Processes.* Sequences of two successive aggressive actions can involve either just two, or all three, members of a triad. There are two possible kinds of sequences involving just two members: one animal attacks another twice in a row (Repeat sequence) or one animal attacks another and the receiver returns the attack (Interchange sequence). Acts numbers 1 and 2 in the Data Excerpt given in Table 4 are an example of a Repeat sequence, and acts numbers 2 and 3 are an example of an Interchange sequence.

These two pairwise sequences, in contrast to the triadic sequences that will be defined below, have no implication, in and of themselves, for the formation of transitive or intransitive triads. Therefore, although the pairwise sequences are interesting in their own right, the analysis here will concentrate on the triadic sequences.

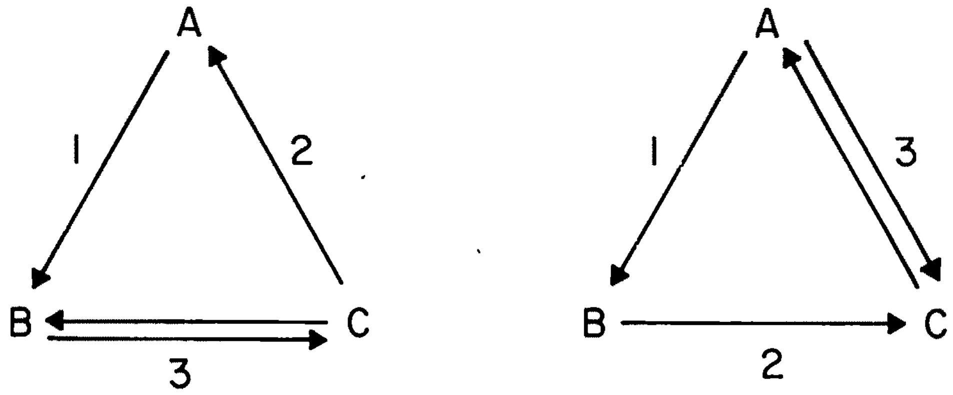
There are four possible sequences involving all three members of a triad. At some point, one member of the triad attacks another member—almost without exception in experimental groups of chickens, attacks involve only two individuals at a time (the problem of coordinated attacks involving three or more individuals at a time, in such animals as primates, will be discussed later). The attacker in this encounter is labeled as A, the receiver as B, and the bystander as C. After A attacks B there are four *and only four* possible sequences involving C. C and A can interact and there are two possibilities here: A can attack C or C can attack A. Or C and B can interact, and there are also two possibilities here: C can attack B or B can attack C. The resulting total of four possible sequences of attacks is shown in Figure 5. Pattern I is the Double Attack sequence: A first attacks B and then A follows with an attack on C. Pattern III is the Attack the Attacker sequence: A attacks B and then A is attacked by C. Pattern II is the Double Receive sequence: A attacks B and then C attacks B. Pattern IV is the Pass On (the Attack) sequence: A attacks B and then B attacks C. In the Data Excerpt of Table 4 acts numbers 3 and 4 form a Double Attack sequence; acts numbers 8 and 9, a Double Receive sequence; acts numbers 7 and 8, a Pass On sequence; and acts numbers 6 and 7, an Attack the Attacker sequence.

Two of these sequences have a different implication for the formation of transitive and intransitive triads based upon attack relationships than do the other two. (The reader should understand that transitivity and intransitivity are properties of relationships in general, not just of dominance relationships. Thus, if A dominates B, B dominates C, and A also dominates C, a transitive triad based on dominance relationships results; and if A attacks B, B attacks C, and A also attacks C, a transitive triad based on attack relationships results.) Patterns I and II, the Double Attack and the Double Receive sequences, guarantee the presence of a triad with transitive attack relationships—no matter what the direction of attack in the third pair of the triad. This lack of dependency upon the attack in the third pair is indicated by the double-headed arrows in Figures 5I and 5II. For example, in the Double Attack sequence, if B later attacks C,



I. Double Attack

II. Double Receive



III. Attack the Attacker

IV. Pass On

Figure 5. The Four Possible Triadic Attack Sequences (Attacks Are Numbered in Order of Occurrence)

the transitive triad in Figure 6A results; or if C later attacks B, the transitive triad in Figure 6B results. The problem of going from transitive triads based upon attack relationships to transitive triads based upon dominance relationships will be treated later.

In direct contrast, the Attack the Attacker and Pass On sequences can give rise to triads with either transitive or intransitive relationships, depending upon the direction of attack in the third pair. For example, in the Attack the Attacker sequence, if C attacks B, the transitive triad in Figure 7A results, but if B attacks C, the intransitive triad in 7B results. This dependency is signified by separate arrows in either direction for the third pair in Figures 5III and 5IV.

Given this difference in attack sequences, a question naturally arises: Are chickens favoring one or both of the sequences that guarantee transitivity over those not favoring transitivity? An analysis was performed to answer this question by determining the usage of the four triadic sequences. In this analysis, the first and second aggressive actions occurring in a triad were examined. If these two actions involved only two members of the triad, then the sequence was categorized as either a Repeat or an Interchange pattern as described above. If, however, the two actions involved first two members of the triad and then the third member, the sequence was categorized as one of the four triadic patterns. After comparing the first and second aggressive actions, the analysis continued by comparing the second and third

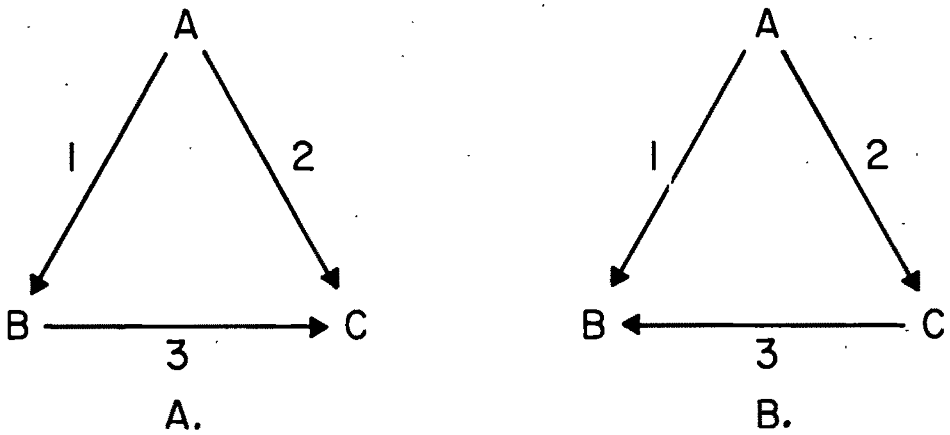


Figure 6. The Two Possible Transitive Triads Resulting from a Third Attack Following the Use of a Double Attack Sequence

actions, the third and fourth, and so on. As a result, in this method of analysis each action is considered once as the first act in a sequence and once as the second act. In addition, this method of analysis reidentifies the initial attacker, the initial receiver, and the bystander for each two-act sequence. Using this method of analysis on the data in Table 4, the first three sequences would be counted in this way: acts 1 and 2 are a Repeat sequence, acts 2 and 3 an Interchange sequence, and acts 3 and 4 a Double Attack sequence.

Distribution of the four sequences as frequencies as well as percentages of all triadic sequences observed in 23 triads combined are given in Table 5. (One triad was omitted from this analysis; this triad had no incidences of triadic sequences and showed only a single Repeat pattern.) Column 6 of the table indicates the total usage of the four sequences not broken down by time between the initial and following acts of the sequence. The Double Attack sequence composes the overwhelming majority of all triadic patterns—86.6%. The Double Receive, Pass On, and Attack the Attacker sequences account for comparatively small percentages—2.7, 5.3, and 5.4, respectively—of all triadic patterns. If attacks are at random, each of the four patterns has an equal (.25) probability of occurring. The actual distribution of sequence patterns is, however, markedly different from that expected by chance

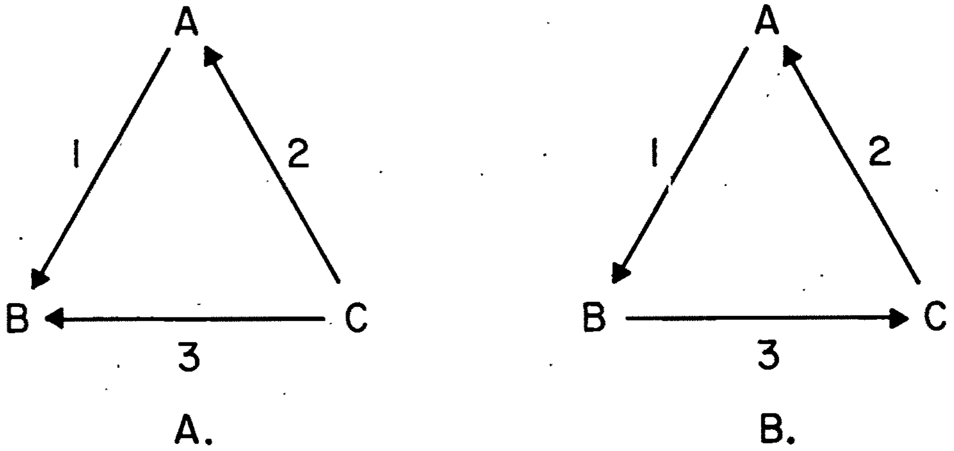

Figure 7. The Possible Transitive (A) and Intransitive (B) Triads Resulting from a Third Attack Following the Use of an Attack the Attacker Sequence

Table 5. Percentage and Frequency Distribution of Triadic Sequences by Time Interval between First and Second Acts (Frequencies Are in Parentheses)

	Time Interval (in sec.)					
Triadic Sequence	0–9.9	10.0–29.9	30.0–59.9	60.0–299.9	Over 300	Total
Double Attack	87.9 (123)	90.3 (102)	88.0 (73)	88.4 (137)	76.8 (76)	86.6 (511)
Double Receive	1.4 (2)	2.7 (3)	2.4 (2)	2.6 (4)	5.0 (5)	2.7 (16)
Pass On	7.1 (10)	.9 (1)	4.8 (4)	4.5 (7)	9.1 (9)	5.3 (31)
Attack the Attacker	3.6 (5)	6.2 (7)	4.8 (4)	4.5 (7)	9.1 (9)	5.4 (32)

(significant at the $p < .001$ level, using a multivariate normal test).

The finding that the Double Attack pattern comprises the large majority of all patterns is robust across sequences, with different time periods between intitial and following acts. This can be seen by examining the first five columns of Table 5 in which sequences are broken down by the time, in seconds, between the initial and following acts. For the first four time periods, the proportion of Double Attacks hovers around 90%, and in the longest period of separation, 300 seconds (five minutes) or more, the proportion drops somewhat to 76.8%.

The finding that most triadic sequences are Double Attacks is also robust across individual experimental groups. Of the 24 experimental triads, there were 10 triads (41.7% of all triads) in which Double Attacks composed more than 90% of all sequences, four triads (16.7%) with between 80% and 89% Double Attacks, five triads (20.8%) with between 70% and 79% Double Attacks, and five triads (20.8%) with 43% or lower Double Attacks. (Considering the distribution of triadic sequences in each triad as a sample point, the vector of mean percentages for the patterns is significant at the $p < .001$ level, using a multivariate normal test.) In 79.2% of the triads, then, Double Attacks composed 70% or more of all triadic sequences, and the mean percentage of Double Attacks in the triads was 74.6%.

These data indicate that: (1) in most triads, most of the time, the chickens use the Double Attack pattern—a kind of sequence that guarantees triads with transitive attack relationships, and (2) in most triads, they only rarely use the Pass On and Attack the Attacker sequences that could possibly lead to intransitive triads. These findings suggest that the extremely high proportion of transitive triads and triads that are guaranteed to be transitive (one animal dominates the other two but the relationship between the subordinates is not settled), based on *dominance* relationships, results from the short-term interaction process of chickens in two ways. First, one chicken in a triad tends to repeatedly enact Double Attacks and, in so doing, she fulfills the dominance criteria vis-à-vis the two other members of the group. Second, although chickens may on occasion use the Pass On and Attack the Attacker sequences, all three chickens in a triad do not enact these sequences in a sufficiently consistent and frequent manner so that dominance criteria over the animals being attacked are actually met. That is, in order to have a triad with intransitive *dominance* relationships there must be sufficient and consistent Pass Ons and/or Attack the Attackers to such a degree that a configuration of the sort in which A dominates B and B dominates C results *and*, further, sufficient and consistent Pass Ons and/or Attack the Attackers to such a degree that C comes to dominate A. Pass On and Attack the Attacker sequences are rare, to begin with, in most triads; and the few that do occur are not used consistently enough by the animals to meet the dominance criteria over their fellows in the proper pattern to form a triad with intransitive *dominance* relationships.

THE FORMATION OF LINEAR AND NEAR-LINEAR HIERARCHIES

I now present two empirically testable hypotheses based upon generalizations from the triad study. I propose that the hypotheses can help to direct research efforts and to explain the formation of linear and near-linear hierarchies—not only in groups of chickens larger than triads but also in other animal species and humans. (Data for some primate species will also be reviewed.) The first hypothesis originates from the long-term structure of the interaction process and the second from the short-term structure.

The first hypothesis is as follows:

> A) the winner of a dominance contest tends to subsequently engage and dominate other individuals not yet dominated, but not individuals to which it is already subordinate;
>
> B) the loser of a dominance contest tends not to attack any bystanders until the individual who has defeated it becomes dominant over the bystanders; and
>
> C) if either or both of the two above conditions are violated, so that either a triad with intransitive dominance relationships or an initial configuration that could lead to an intransitive triad arises, then one individual will reverse an existing relationship in such a manner that a transitive triad or an initial configuration guaranteeing a transitive triad will result.

This necessarily somewhat complicated way of verbally stating the hypothesis simply implies that the initial configuration of dominance relationships (in most of the possible triads making up a large group) will be of the type in which A dominates both B and C or in which A and C both dominate B but not in which A dominates B and B dominates C. If either of the first two configurations is present, a triad is guaranteed to be transitive; and if all or most of the possible triads in a group have transitive dominance relationships or are guaranteed to be transitive, the hierarchy formed by the concatenation of the triads will be linear or near-linear. One possible scenario of hierarchy formation arising from this hypothesis—and which I predict to occur very frequently—is as follows: One individual in a group wins successive dominance contests with all the other group members and each loser, in turn, withdraws from aggressive activity. After this first member has finished, one of the subordinates initiates and wins contests with all the other subordinates who again temporarily withdraw from aggressive activity. Then, a second of the original subordinates gains dominance over all but the initial dominant and the first subordinate, and so on, until a complete linear hierarchy is established. In another likely scenario, two individuals each win one or more dominance contests with other group members. After this, the two winning individuals meet in a dominance encounter, and the winner goes on to dominate any remaining group members not yet dominated, while the loser withdraws temporarily from aggressive activity according to part B of the hypothesis.

As indicated, intransitive triads and initial configurations that could lead to intransitive triads do arise when the usual strategies of winners and losers are not followed. Part C of the hypothesis suggests that (1) these structures are not as stable as actual transitive triads or configurations which guarantee transitivity, and (2) previously formed dominance relationships will be reversed to give transitive structures. Part C, in effect, indicates how individuals respond when there is an exception to parts A and B. Other researchers have also found that intransitive triads are not as stable as transitive ones in animals and tend to be converted to transitive structures (Murchison, 1935; Tordoff, 1954). Similarly, Hallinan (1974) and Holland and Leinhardt (1971) postulate that humans have a strong tendency to transform initially intransitive configurations of preference relations to transitive ones.

The second hypothesis states: The Double Attack pattern will be the most frequent of all sequences of two successive attacks involving more than two individuals. In other words, this hypothesis suggests that, of the four possible triadic sequences and the one possible tetradic sequence (A attacks B followed by C attacks D), the most frequent sequence will be the Double Attack pattern. If this hypothesis is supported, then most sequences that occur will generate configurations of attack relationships that guarantee transitivity and those that generate configurations that do not guarantee transitivity will be rare. I would like to hedge (somewhat) my bet on this hypothesis by suggesting that in groups larger than three and which remain together for longer periods there might be a considerable occurrence of Double Receive sequences. This hedge is based upon preliminary observation of larger groups of chickens and on some data for primates which will be reviewed below. In some groups there is what might be called "scapegoating"—several members successively attack one low-ranking individual. These successive attacks on the "scapegoat" generate large numbers of Double Receive patterns. In any event, the Double Receive pattern, like the Double Attack, guarantees a transitive attack configuration, and either one or both patterns working together would help produce linear and near-linear hierarchies.

AGGRESSIVE SEQUENCES IN PRIMATES

The hypotheses presented above are derived from my own observational studies of chickens, and one might question the applicability of these hypotheses to other animal species and to humans. Are there indeed similar long- and short-term processes in the interactions of humans and other species that help to explain the reported prevalence of linear and near-linear hierarchies? As I mentioned earlier, animal behaviorists, sociologists, and social psychologists have provided relatively few studies of the dynamics by which hierarchies are formed. It is, therefore, not possible at the present time to rigorously test the validity of these hypotheses for human and other animal groups. There are, however, some suggestive reports in the primate literature and these shall now be reviewed. These studies give information about sequences of aggressive acts in primate groups with previously established relationships rather than sequences during the formation of dominance relationships as in the chicken experiment.[1] I have found no quantitative studies of the strategies used by winners and losers during the formation of relationships in primate groups.

Each of the four triadic sequences described has also been reported in various primate species. For example, the Double Receive sequence is reported in rhesus monkeys, Java monkeys, baboons, and langurs (Varley and Symmes, 1966; De Waal et al., 1976; Cheney, 1977; Hall and DeVore, 1965; Jay, 1965). Although the Double Attack sequence figures prominently in the results reported here, it has received relatively little recognition as an explicit sequence in primates (which is not to say that it is rare). It is, however, reported in Java monkeys, baboons, and langurs (De Waal, et al., 1976; Hall and DeVore, 1965; Jay, 1965). The Pass On pattern is most recognized as an explicit sequence in primates, and it is referred to by a variety of terms including "redirected," "transferred," or "displaced" aggression. Pass On sequences are reported for rhesus monkeys, Java monkeys, and baboons (Altmann, 1962; Kaufmann, 1967; Jay, 1965; De Waal, et al., 1976; Hall and DeVore, 1965). In some cases an animal attacked redirects the aggression to an inanimate object (Hall and DeVore, 1965). The Attack the Attacker sequence is frequently observed in primate groups when an individual aids a related animal being attacked, but it also occurs among nonrelated animals. This sequence is reported for pig-tailed monkeys, Java monkeys, and langurs (Tokuda and Jensen, 1968; De Waal, et al., 1976; Jay, 1965).

Of these studies, only the one by De Waal et al. (1976) on Java monkeys, close cousins of the more familiar rhesus monkeys, reports the actual frequencies of occurrence of the four triadic sequence patterns.[2] Their study group was considerably different from those in my experiment; it consisted of 17 animals of both sexes and of varying ages from infants to adults. The individuals had been together for a relatively long time, and it is probably safe to assume that most dominance relationships were firmly established rather than in the process of being formed. Their methods of counting triadic sequences were also different from those used in the chicken study. In order to count as a triadic sequence, A had to attack B and one of these two had to be involved in an attack with C less than 15 seconds later. If the second attack took more than 15 seconds, the interactions counted as separate dyadic attacks rather than as one triadic sequence.

---

[1] A particular aggressive sequence used during the formation of dominance relationships may have a different implication than the same sequence used after dominance relationships have been formed. For example, if A attacks B, and B passes on the attack to C, then there is at least a logical possibility that C might later attack A to form an intransitive triad if A does not already dominate C. On the other hand, if A already dominates both B and C and B dominates C, then the same Pass On sequence would not make an intransitive triad possible because C, in all probability, would not later attack A.

Their data indicate that as proportions of all triadic sequences there were 39.7% Double Receives, 22.2% Double Attacks, 20.6% Pass Ons, and 17.5% Attack the Attackers (De Waal et al., 1976:273). In these data, the Double Recieve pattern was used most frequently, with Double Attack a relatively distant second, followed closely by Pass On and Attack the Attacker. Although the Double Attack pattern does not make up the majority of all sequences in the Java monkeys as it did in the chickens, in both groups sequences which guarantee triads with transitive attack relationships are considerably more frequent than those which can lead to either transitive or intransitive triads. That is, the Double Receive and the Double Attack patterns, together, account for 61.9%, a majority of all triadic sequences in the monkeys. There is, then, agreement on the high proportion of sequences guaranteeing triads with transitive attack configurations between the experiment for chickens and one for a primate group under quite different conditions.

These data provide partial corroboration of the second hypothesis proposed above, but they also suggest certain refinements may be necessary for primates. Additional experiments under controlled conditions for both chickens and primates are required to ascertain the extent of the refinements. One necessary refinement concerns the presence of coalitions in primate groups. By coalition in this context I simply mean two or more individuals directly coordinated, interspersed aggressive acts toward another individual. Coalitions in primate groups are mainly of two sorts: (1) two or more animals join in attacking a third, and (2) one or more animals come to the defense of an animal being attacked and attack the original aggressor. These kinds of coalitions are commonly observed, for example, in baboons, rhesus monkeys, vervet monkeys, langurs, and Java monkeys (Cheney, 1977; Southwick et al., 1965; Varley and Symmes, 1966; Struhsaker, 1967; Jay, 1965; De Waal et al., 1976). The first kind of coalition can be considered as a modified type of Double Receive sequence; in this case the successive attacks are made by animals actively coordinating their aggressive actions. In a similar fashion, the second type of coalition can be considered as a variant of the Attack the Attacker sequence. Thus, the hypothesis proposed above concerning the short-term structure of aggressive interactions can be tested in socially complex species like humans and primates as well as in socially simpler animals using both the simple and modified forms of the triadic sequence patterns.

CONCLUSION

For both social scientists and animal behaviorists there are, arguably, three central issues in the study of social structure in small, face-to-face groups: formation, delineation, and consequence. Confronted with a small-group social structure, a researcher in either field might ask how the relationships came about, what the pattern of relationships was like, and what privileges or liabilities were associated with various positions in the structure. Both social scientists and animal behaviorists have made considerable progress with the last two of these issues, but neither group, as I have shown here through the example of hierarchy studies, has dealt satisfactorily with the formation of social structures. An analysis of the extant research demonstrates that common conceptual and methodological problems underlie the inadequacies of each field in dealing with the formation of hierarchy structures. Although it takes many different outward appearances, the conceptual machinery in both fields mainly tries to explain the formation of dominance hierarchies by differences in individual characteristics (including differences of ability in pairwise encounters). Given this conceptual machinery, social scientists and animal behaviorists have developed a variety of sophisticated techniques to measure differences among individuals along a variety of dimensions. I have indicated here that, no matter how sophisticated the techniques of measurement or the models using individual differences, stringent mathematical conditions must be met before this approach can satisfactorily explain the empirically common linear and near-linear hierarchies. This emphasis on measuring things about individuals before they join a group, and correlating these measurements with their subsequent positions, leaves out what happens in between: the behavioral process by which individuals come to take their positions. Thus, the present theoretical approach in both human social sciences and animal behavior has led to a relative absence of empirical studies of the dynamics of hierarchy formation.

---

[2] Although Kummer (1975) does not count frequencies of behavioral sequences, he does present a stimulating analysis which suggests that interactions in mixed-gender triads can help to explain dominance relationships and sexual alliances in larger groups.

Herein, I offer a new and more satisfactory conceptual and methodological framework for the study of hierarchy formation. Here, the structure of the interaction process is seen as explaining the formation of a hierarchy, and the associated methodology deals with recording and analyzing the interactions among group members. Here, also, this approach is shown to view social structure as emerging from the web of interactions, and it naturally requires studies of the dynamic processes which result in hierarchy formation.

The application of this alternative approach led to the discovery of a short-term process, the predominant use of the Double Attack sequence, and a long-term process (usual patterns of behavior by winners and losers) that helped to explain the presence of actual transitive triads and configurations guaranteeing transitivity. These findings generated two hypotheses which proposed explanations for the presence of linear and near-linear hierarchies in animal and human small groups. A review of the primate literature offered partial support for one hypothesis, and it suggested modifications to make the hypothesis more generally applicable.

The results presented here suggest three major implications for future research on hierarchy formation, in particular—and on other kinds of social structures, in general.

The first implication is that the explicit and implicit assumptions made by explanations for the formation of various kinds of social structures should be critically examined. Other explanations based upon individual differences may also suffer from inherent liabilities similar to those for dominance hierarchies. This critical examination would, in appropriate circumstances, include explanations in both human social science and animal behavior. For example, profitable areas of investigation are likely to be wealth and income distribution in humans, resource distributions (mates, territories, etc.) in animals, and leadership and role structure in human small groups (see Chase, 1980, for a criticism of population genetics models as proximate explanations of cooperative and noncooperative behavior in animals).

The second implication is that dynamic studies of dominance and other kinds of relationships can greatly increase our knowledge of small-group phenomena. The lack of such studies is partly explained, as discussed above, by the conceptual framework of present approaches and, partly, it seems likely, by the previous lack of efficient equipment for the recording, storage, and analysis of the necessarily large volumes of interactional data. The growing availability of microcomputer systems and computer-assisted devices for dealing with interactional data is rapidly alleviating this problem.

The third implication is that there is a certain "lawfulness" in the structure of interactions that can explain the configurations of social relationships in small groups. This article demonstrates "lawfulness" in the interactions of chickens in triads, and it goes on to suggest the units of interaction that are responsible for hierarchy formation in larger groups across species. The model developed here indicates how interactions at a micro level—among individuals—can be cumulated to explain how a macro level structure—a dominance hierarchy—is produced.

I suggest that this kind of approach has applicability beyond hierarchy research to the study of other types of social structure in human and animal groups. Future research is needed to assess the validity of this implication.

WEBER'S LAST THEORY OF CAPITALISM: A SYSTEMATIZATION*

RANDALL COLLINS
University of Virginia

American Sociological Review 1980, Vol. 45 (December):925–942

A systematic formulation is given of Weber's theory of the origins of large-scale capitalism, based upon the lectures given just before his death. This last theory is predominantly institutional, unlike the emphasis upon religious ideas and motivations in his early Protestant Ethic thesis, and unlike his analyses of the world religions. Weber's institutional theory involves a sequence of causal conditions. The outcome of the sequence is capitalism characterized by the entrepreneurial organization of capital, rationalized technology, free labor, and unrestrained markets. Intermediate conditions are a calculable legal system and an economic ethic combining universal commercialization with the moderate pursuit of repetitive gains. These conditions are fostered by the bureaucratic state and by legal citizenship, and more remotely by a complex of administrative, military, and religious factors. The overall pattern is one in which numerous elements must be balanced in continuous conflict if economic development is to take place. Weber derived much of this scheme in explicit confrontation with Marxism. His conflict theory criticizes as well as deepens and extends a number of Marxian themes, including a theory of international capitalism which both criticizes and complements Wallerstein's theory of the world system.

Max Weber had many intellectual interests, and there has been considerable debate over the question of what constitutes the central theme of his life work. Besides treating the origins of capitalism, Weber dealt extensively with the nature of modernity and of rationality (Tenbruck, 1975; Kalberg, 1979; 1980; Seidman, 1980), and with politics, methodology, and various substantive areas of sociology. Amid all the attention which has been paid to these concerns, one of Weber's most significant contributions has been largely ignored. This is his mature theory of the development of capitalism, found in his last work (1961), *General Economic History*.

This is ironic because Weber's (1930) first major work, *The Protestant Ethic and the Spirit of Capitalism*, has long been the most famous of all. The argument that the Calvinist doctrine of predestination gave the psychological impetus for rationalized, entrepreneurial capitalism is only a fragment of Weber's full theory. But many scholars have treated it as Weber's distinctive contribution, or Weber's distinctive fallacy, on the origins of capitalism (e.g., Tawney, 1938; McClelland, 1961; Samuelsson, 1961; Cohen, 1980). Debate about the validity of this part of Weber's theory has tended to obscure the more fundamental historical and institutional theory which he presented in his later works.

The so-called "Weber thesis," as thus isolated, has been taken to be essentially idealist. Weber (1930:90) defines his purpose in *The Protestant Ethic* as "a contribution to the manner in which ideas become effective forces in history." He (1930:183) polemically remarks against the Marxists that he does not intend to replace a one-sided materialism with its opposite, but his correcting of the balance sheet in this work concentrates largely on ideal factors. The germ of Weber's institutional theory of capitalism can also be found in *The Protestant Ethic* (1930:58, 76).[1] But it remained an undeveloped backdrop for his main focus on the role of religious ideas. The same may be said about his (1951; 1952; 1958b) comparative studies of

I am indebted to Vatro Murvar and other participants at the Max Weber Symposium at the University of Wisconsin at Milwaukee, March, 1978, and to Samuel W. Kaplan, Stephen Kalberg, Guenther Roth, Walter Goldfrank, Norbert Wiley, and Whitney Pope, for their suggestions on an earlier version of this argument.

[1] The list of institutional characteristics given on pp. 21–25 of the English-language edition of *The Protestant Ethic* (1930), however, are not in the 1904–5 original, but are from an introduction written in 1920 (1930:ix–x).

the world religions. These broadened considerably the amount of material on social, economic, and political conditions, but the main theme still stressed that divergent ideas made an autonomous contribution to the emergence of world-transforming capitalism in the Christian West rather than elsewhere in the world.[2] Thus, Parsons (1963; 1967) treats these works as extending the early Weber thesis from Protestantism to Christianity in general, describing an evolution of religious ideas and their accompanying motivational propensities from ancient Judaism up through the secularized achievement culture of the modern United States.

From these works, and from (1968) Part II of *Economy and Society*, it is possible to pull out an extensive picture of institutional factors which Weber includes in his overall theory of capitalism. But *Economy and Society* is organized encyclopedically, by analytically defined topics, and does not pull together the theory as a whole. There is only one place in Weber's works where he brings together the full theory of capitalism as a historical dynamic. This is in the *General Economic History*, and, especially, in the 70-page section comprising Part IV of that work. These lectures, delivered in the winter and spring of 1919–20, before Weber's death that summer, are Weber's last word on the subject of capitalism. They are also the most neglected of his works; *General Economic History* is the only one of Weber's major works that remains out of print today, both in English and in German.

One important change in the *General Economic History* is that Weber pays a good deal more attention to Marxian themes than previously. This is a significant difference from the anti-Marxist comments scattered through *The Protestant Ethic* (e.g., pp. 55–56, 61, 90–91, 183). In the *General Economic History*, Weber reduces the ideal factor to a relatively small place in his overall scheme. During this same period, to be sure, Weber was preparing a new introduction and footnotes for the reissue of *The Protestant Ethic* among his collected religious writings, in which he defended his original thesis about Calvinism. But his claims for its importance in the overall scheme of things were not large, and the well-rounded model which he presents in *General Economic History* does not even mention the doctrine of predestination. Instead, what we find is a predominantly institutional theory, in which religious *organization* plays a key role in the rise of modern capitalism but especially in conjunction with particular forms of political organization.

In what follows, I will attempt to state systematically Weber's mature theory of capitalism, as it appears in the *General Economic History*, bolstered where appropriate by the building blocks presented in *Economy and Society*. This argument involves a series of causes, which we will trace backward, from the most recent to the most remote. This model, I would suggest, is the most comprehensive general theory of the origins of capitalism that is yet available. It continues to stand up well in comparison with recent theories, including Wallerstein's (1974) historical theory of the capitalist world-system.

Weber himself was primarily concerned with the sensitizing concepts necessary for an interpretation of the unique pattern of history and, in his methodological writings, he disavowed statements in the form of general causal principles (cf. Burger, 1976). Nevertheless, Weber's typologies contain implicit generalizations about the effects of institutional arrangements upon each other, and statements of cause-and-effect abound in his substantive writings. There is nothing to prevent us from stating his historical picture of changing institutional forms in a more abstract and generalized manner than Weber did himself.

---

[2] Cf. the closing words of *The Religion of China:* "To be sure the basic characteristics of the 'mentality,' in this case practical attitudes towards the world, were deeply co-determined by political and economic destinies. Yet, in view of their autonomous laws, one can hardly fail to ascribe to these attitudes effects strongly counteractive to capitalist development" (1951:249), and of *The Religion of India:* "However, for the plebeian strata no ethic of everyday life derived from its rationally formed missionary prophecy. The appearance of such in the Occident, however—above all, in the Near East—with the extensive consequences borne with it, was conditioned by highly particular historical constellations without which, despite differences of natural conditions, development there could easily have taken the course typical of Asia, particularly of India" (1958b:343).

Weber's model continues to offer a more sophisticated basis for a theory of capitalism than any of the rival theories of today. I put forward this formalization of Weber's mature theory, not merely as an appreciation of one of the classic works of the past, but to make clear the high-water mark of sociological theory about capitalism. Weber's last theory is not the last word on the subject of the rise of capitalism, but if we are to surpass it, it is the high point from which we ought to build.

THE COMPONENTS OF RATIONALIZED CAPITALISM

Capitalism, says Weber (1961:207–8, 260) is the provision of human needs by the method of enterprise, which is to say, by private businesses seeking profit. It is exchange carried out for positive gain, rather than forced contributions or traditionally fixed gifts or trades. Like all of Weber's categories, capitalism is an analytical concept; capitalism can be found as part of many historical economies, as far back as ancient Babylon. It became the indispensable form for the provision of everyday wants only in Western Europe around the middle of the nineteenth century. For this large-scale and economically predominant capitalism, the key is the "rational permanent enterprise" characterized by "rational capital accounting."

The concept of "rationality" which appears so often in Weber's works has been the subject of much debate. Marxist critics of capitalism, as well as critics of bureaucracy, have attacked Weber's alleged glorification of these social forms (e.g., Hirst, 1976). On the other hand, Parsons (1947), in his long introduction to the definitional section of *Economy and Society,* gives "rationalization" both an idealist and an evolutionary bent, as the master trend of world history, involving an inevitable upgrading of human cognitive and organizational capacities. Tenbruck (1975) claims the key to Weber's works is an inner logic of rational development found within the realm of religious solutions to the problem of suffering.

It is clear that Weber himself used the term "rationalism" in a number of different senses.[3] But for his *institutional* theory of capitalist development, there is only one sense that need concern us. The "rational capitalistic establishment," says Weber (1961:207), "is one with capital accounting, that is, an establishment which determines its income yielding power by calculation according to the methods of modern bookkeeping and the striking of a balance." The key term is *calculability;* it occurs over and over again in those pages. What is distinctive about modern, large-scale, "rational" capitalism—in contrast to earlier, partial forms—is that it is methodical and predictable, reducing all areas of production and distribution as much as possible to a routine. This is also Weber's criterion for calling bureaucracy the most "rational" form of organization.[4]

---

[3] In Part I of *Economy and Society* (written 1918–20), Weber distinguishes formal and substantive rationality of economic action (1968:85–6). In "The Social Psychology of the World Religions" (written 1913), Weber (1946:293–4) defines three different types of rationalism: (1) a systematic world view based on precise, abstract concepts; (2) practical means-ends calculations; (3) a systematic method, including that of magic or prayer. In *The Protestant Ethic* (1904–5), Weber (1930:76–78) attacks the notion that the spirit of capitalism is "part of the development of rationalism as a whole," and says he is interested in "the origin of precisely the irrational element which lies in this, as in every conception of a calling." Kalberg (1980) points out that under one or another of Weber's types of rationality, *every* action, even the most superstitious, might be called "rational." Kalberg argues that only one type of rationality is relevant for the methodical conduct of affairs.

[4] It is plain that Weber (1968:85–6) is referring to what in *Economy and Society* he calls "formal" rationality, efficiency based on quantitative calculation of means, rather than "substantive" rationality, the adequacy of actions for meeting ultimate values. Such values could be criteria of economic welfare, whether maximal production, quality of life, or a socialist economic distribution, or they could be ethical or religious values. Weber makes it clear that formal and substantive rationality can diverge widely, especially in his late political writings about the dangers of bureaucracy (1946:77–128; 1968:1393–1415). Weber himself tended to defend the formal rationality of modern capitalism as coinciding to a fair degree with substantive rationality in meeting the value of maximizing the economic welfare of the population at large (1968:108–9). It goes

For a capitalist economy to have a high degree of predictability, it must have certain characteristics. The logic of Weber's argument is first to describe these characteristics; then to show the obstacles to them that were prevalent in virtually all societies of world history until recent centuries in the West; and, finally, by the method of comparative analysis, to show the social conditions responsible for their emergence.

According to his argument, the components of "rationalized" capitalism are as follows:

There must be *private appropriation of all the means of production,* and their concentration under the control of entrepreneurs. Land, buildings, machinery, and materials must all be assembled under a common management, so that decisions about their acquisition and use can be calculated with maximal efficiency. All these factors must be subject to sale as private goods on an open market. This development reaches its maximal scope when all such property rights are represented by commercial instruments, especially shares in ownership which are themselves negotiable in a stock market.

Within this enterprise, capital accounting is optimized by a *technology which is "reduced to calculation to the largest possible degree"* (1961:208). It is in this sense that mechanization is most significant for the organization of large-scale capitalism.

Labor must be free to move about to any work in response to conditions of demand. Weber notes that this is a formal and legal freedom, and that it goes along with the economic compulsion of workers to sell their labor on the market. Capitalism is impossible without a propertyless stratum selling its services "under the compulsion of the whip of hunger" (1961:209), for only this completes a mass market system for the factors of production which makes it possible to clearly calculate the costs of products in advance.

Trading in the market must not be limited by irrational restrictions. That is to say, noneconomic restrictions on the movement of goods or of any of the factors of production must be minimized. Such restrictions include class monopolies upon particular items of consumption (such as sumptuary laws regulating dress), or upon ownership or work (such as prohibitions on townspeople owning land, or on knights or peasants carrying on trade; more extensively, caste systems in general). Other obstacles under this heading include transportation difficulties, warfare, and robbery—which make long-distance trading hazardous and unreliable.

Finally, there must be *calculable law, both in adjudication and in public administration.* Laws must be couched in general terms applicable to all persons, and administered in such a way as to make the enforcement of economic contracts and rights highly predictable. Such a legal system is implicated in most of the above characteristics of rational capitalism: the extension of private property rights over the factors of production; the subdivision and easy transferability of such rights through financial instruments and banking operations; formal freedom for laborers; and legally protected markets.

The picture that Weber gives us, then, is of the institutional foundations of the market as viewed by neoclassical economics. He sees the market as providing the maximal amount of calculability for the individual entrepreneur. Goods, labor, and capital flow continuously to the areas of maximal return; at the same time, competition in all markets reduces costs to their minimum. Thus, prices serve to summarize all the necessary information about the optimal allocation of resources for maximizing profit; on this basis, entrepreneurs can most reliably make calculations for long-term production of large amounts of goods. "To sum up," says Weber (1961:209), "it must be possible to conduct the provision for needs exclusively on the basis of market opportunities and the calculation of net income."

It is, of course, the model of the laissez-faire capitalist economy that Weber wishes to ground. At the extreme, this is an unrealistic view of any economy that has ever existed. Weber treats it as an ideal type and, hence, in a fuller exposi-

---

without saying that this is an empirical, not an analytical judgment.

tion would doubtless have been prepared to see it as only partially realized even in the great capitalist takeoff period of the nineteenth century. But it is worth noting that a critique of Weber along these lines could certainly not be a classical Marxian one. The central dynamic of capitalism in Marx's theory, in fact, depends even more immediately than Weber's on the unrestricted competitiveness of the open market for all factors of production (cf. Sweezy, 1942). And Weber and Marx agree in claiming that the initial breakthrough to an industrial society had to occur in the form of capitalism. Thus, although Weber may have a personal bias toward the neoclassical market economy, both as analytical model and as political preference, this would give no grounds for a critique of the adequacy of his explanation of this phase of world history. Even for a later period, Weber is hardly dogmatic. As we shall see, he recognizes the possibility of socialism emerging, once capitalism has matured—although he does not admire the prospect—and he even gives some indications of the forces that might produce it. Like German and Austrian non-Marxist economists of his generation, Weber includes socialism within his analytical scheme.

Weber's model of the modern economy is particularly striking with regard to the concept of the "industrial revolution." For it is not mechanization per se that is the key to the economic transformation, despite the far-reaching consequences of shifts from agrarian to inanimate-energy-based technologies (cf. Lenski, 1966). In Weber's scheme, technology is essentially a dependent variable. The key *economic* characteristic of mechanization is that it is feasible only with mass production (Weber, 1961:129, 247). The costs of even simpler machines such as steam-powered looms would make them worthless without a large-scale consumers' market for cloth, as well as a large-scale producers' market in wool or cotton. Similar considerations apply a fortiori to machinery on the scale of a steel rolling mill. But large-scale production is impossible without a high degree of predictability that markets will exist for the products, and that all the factors of production will be forthcoming at a reasonable cost. Thus, mechanization depends on the prior emergence of all the institutional factors described above.

Weber does not elaborate a systematic theory of technological innovation, but it would be possible to construct one along these lines. He does note that all the crucial inventions of the period of industrial takeoff were the result of deliberate efforts to cheapen the costs of production (1961:225–6, 231). These efforts took place because previous conditions had intensified the capitalist pursuit of profits. The same argument could be made, although Weber did not make it, in regard to the search for methods to improve agricultural production that took place in the seventeenth and eighteenth centuries. The "green revolution" which preceded (and made possible) the industrial revolution was not a process of mechanization (agricultural mechanization took place only in the late nineteenth century) but was, more simply, the application of capitalist methods of cost accounting to hitherto traditional agriculture. Thus, it is the shift to the calculating practices of the capitalist market economy which makes technological innovation itself predictable, rather than, as previously, an accidental factor in economic life (1961:231).[5]

THE CAUSAL CHAIN

What are the social preconditions for the emergence of capitalism as thus described?

Note, first of all, that economic life, even in the most prosperous of agrarian societies, generally lacked most of these traits. Property systems frequently tied land ownership to aristocratic status, while commercial occupations were often prohibited to certain groups and monopolized by others. The labor force was generally unfree—being either slaves or tied to the land as serfs. Technologies of mass production hardly existed. The market was generally limited either to local areas or to long-distance trade in luxuries, due to numerous near-confiscatory tax barriers, unreliable and varying coinage, warfare, robbery, and poor transportation. And legal systems, even in literate states, tended to be characterized by patrimonial or magical-religious procedures, by differential application to different social groups and by different localities, and by the practices of officials seeking private gain. Reliable financial transactions, including the operation of a banking system relatively free from political interference and plundering, were particularly handicapped by these conditions.

---

[5] Weber does mention "rational science and in connection with it a rational technology" (1961:232) as one of the features of the West important for modern capitalism. On the other hand he says: "It is true that most of the inventions of the 18th century were not made in a scientific manner. . . . The connection of industry with modern science, especially the systematic work of the laboratories, beginning with Justus von Liebig [i.e., *Circa* 1830], enabled industry to become what it is today and so brought capitalism to its full development." On the balance, I think science comes out as a secondary factor in the model.

The social preconditions for large-scale capitalism, then, involved the destruction of the obstacles to the free movement or economic transfer of labor, land, and goods. Other preconditions were the creation of the institutional supports for large-scale markets, especially the appropriate systems of property, law, and finance.

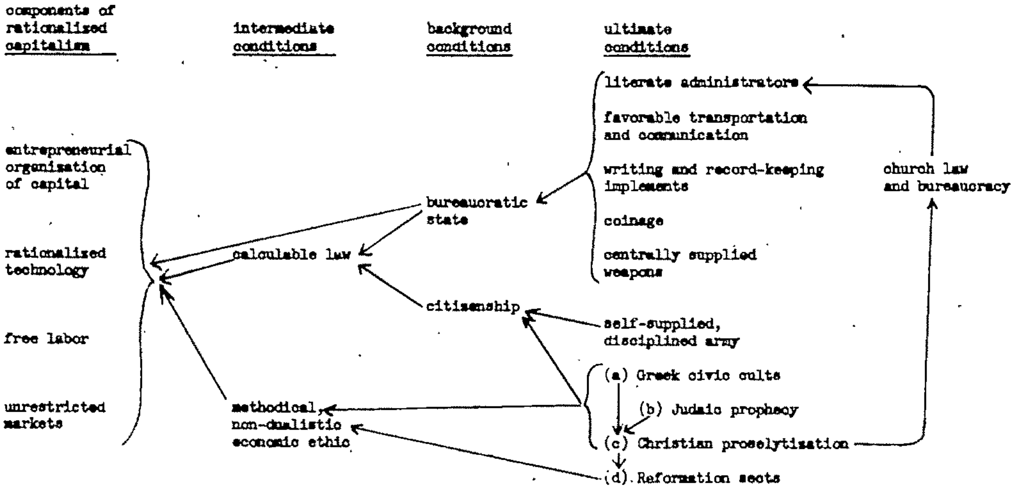
These are not the only preconditions of capitalism, but, specifically, Weber is seeking the organizational forms that made capitalism a world-transforming force in the West but not elsewhere. By a series of comparisons, Weber shows that a number of other factors that have been advanced to account for the Western takeoff cannot have been crucial. Against Sombart, he points out that standardized mass production for war cannot have been decisive for, although a good deal of this existed in Europe in the seventeenth century, and thereafter, it also existed in the Mogul Empire and in China without giving an impetus to capitalism (1961:229). Similarly, the enormous expenditures for court luxury found in both Orient and Occident were incapable of generating a mass market (1961:229–30). Against the simpler arguments of Adam Smith, which attribute the industrial division of labor to the extension of trade, Weber points out that trade can be found everywhere, even in the Stone Age. In ancient Babylon, for example, trade was such as to disintegrate "primitive economic fixity" to a considerable degree (1961:232). On the other hand, politically determined agrarian economies show how "specialization takes place without exchange" (1961:103). Nor is the pursuit of profit per se the crucial motive for mass capitalism; the "ruthlessness" and "unscrupulousness" of the traditional foreign trader was incapable of transforming the economy at large (1961:232). Nor can population growth have been the cause of Western capitalism, for the same trend occurred in China without the same result (1961:258–9). Neither, finally, can the price revolution of the sixteenth century, due to the influx of precious metals from the Americas, have been decisive (see the later discussion on Wallerstein).[6]

The features that Weber finds unique to the West constitute a causal chain.[7] I have represented this schematically in Figure 1. The characteristics of rational capitalism itself are the entrepreneurial organization of capital, rational technology, free labor, unrestricted markets, and calculable law. These make up a complex: the markets for goods, labor, and capital all mesh around entrepreneurial property using mass production technology; the operation of all of these factors together creates further pressures to both rationalize technology and expand each factor market—while yet distributing wealth in such a way as to further the demand. The legal system is both an ongoing prop for all of these features and a causal link backward to their

---

[6] Weber (1961:260) also mentions geographical conditions as more favorable to capitalism in Europe than in China or India, due to transportation advantages in the former via the Mediterranean sea and the interconnecting rivers. But he goes on (p. 261) to discount this, in that no capitalism arose in Mediterranean antiquity, when civilization was predominantly coastal, whereas early modern capitalism in Europe was born in the cities of the interior.

[7] Weber does not clearly describe a chain, and sometimes he lumps characteristics of rational capitalism with its preconditions. Although some of these preconditions continue into the operation of modern capitalism, a logical chain of explanation, I believe, requires something like the separation I have given. It should be understood that Weber gives a highly condensed summary in these lectures.



components of rationalized capitalism
intermediate conditions
background conditions
ultimate conditions
literate administrators
favorable transportation and communication
writing and record-keeping implements
coinage
centrally supplied weapons
church law and bureaucracy
entrepreneurial organization of capital
rationalized technology
free labor
unrestricted markets
bureaucratic state
calculable law
citizenship
self-supplied, disciplined army

(b) Judaic prophecy
(c) Christian proselytization
(d) Reformation sects
methodical, non-dualistic economic ethic

Figure 1. The Weberian Causal Chain

social preconditions. At this intermediate causal level there is a second crucial factor which, like the law, is essentially cultural, although not in the sense of disembodied ideas, but, rather, in the sense of beliefs expressed in institutionalized behavior. This is the "lifting of the barrier . . . between internal and external ethics" (1961:232).

In virtually all premodern societies there are two sharply divergent sets of ethical beliefs and practices. Within a social group, economic transactions are strictly controlled by rules of fairness, status, and tradition: in tribal societies, by ritualized exchanges with prescribed kin; in India, by rules of caste; in medieval Europe, by required contributions on the manor or to the great church properties. The prohibition on usury reflected this internal ethic, requiring an ethic of charity and the avoidance of calculation of gain from loans within the community (cf. Nelson, 1949).[8] In regard to outsiders, however, economic ethics were at the opposite extreme: cheating, price gouging, and loans at exorbitant interest were the rule. Both forms of ethic were obstacles to rational, large-scale capitalism: the internal ethic because it prevented the commercialization of economic life, the external ethic because it made trading relations too episodic and distrustful. The lifting of this barrier and the overcoming of this ethical dualism were crucial for the development of any extensive capitalism. Only this could make loans available regularly and promote the buying and selling of all services and commodities for moderate gain. Through innumerable daily repetitions, such small (but regular) profits could add up to much more massive economic transactions than could either the custom-bound or the predatory economic ethics of traditional societies.

What, then, produced the calculable legal system of saleable private property and free labor and the universal ethic of the pursuit of moderate economic profit? The next links in the causal chain are political and religious. The bureaucratic state is a crucial background determinant for all legal and institutional underpinnings of capitalism. Moreover, its legal system must be based on a concept of universal citizenship, which requires yet further political preconditions. The religious factor operates both as a direct influence on the creation of an economic ethic and as a final level of causality implicated in the rise of the rational-legal state and of legal citizenship.

The state is the factor most often overlooked in Weber's theory of capitalism. Yet it is the factor to which he gave the most attention; in *Economy and Society,* he devoted eight chapters of 519 pages to it, as opposed to one chapter of 236 pages to religion, with yet another chapter—the neglected but very important chap. XIV of Part II—to the relations between politics and religion. In the *General Economic History,* he gives the state the two penultimate chapters, religion the final chapter. For Weber, this political material was not an extraneous interest but, instead, the key to all of the *institutional* structures of rational capitalism. Only the West developed the highly bureaucratized state, based on specialized professional administrators and on a law made and applied by full-time professional jurists for a populace characterized by rights of citizenship. It is this bureaucratic-legal state that broke down feudalism and patrimonialism, freeing land and labor for the capitalist market. It is this state that pacified large territories, eliminated internal market barriers, standardized taxation and currencies. It is this state that provided the basis for a reliable system of banking, investment, property, and contracts, through a rationally calculable and universally applied system of law courts. One may even argue that the bureaucratic state was the proximate cause of the impulse to rationalization, generally—above all, via the late seventeenth- and eighteenth-century spirit of enlightened absolutism, which set the stage for the industrial revolution.

---

[8] Hence the role of "guest peoples" such as the Jews and the Caursines in Christian Europe, or the Christians in Islamic societies, or the Parsees in India, as groups of tolerated outsiders who were available for making loans, which otherwise would not be forthcoming within the controlled internal economy (1961:267).

There are three causal questions about the rational/legal state. Why did it rise to predominance? Where did its structural characteristics come from? How did its legal system take the special form of conceiving of its subjects as holding the rights of citizenship?

The first question is easily answered. The bureaucratic state rose to predominance because it is the most efficient means of pacifying a large territory. It is effective externally in that it can supply a larger military, with better weapons, than can nonbureaucratic states; and it is effective, internally, as it tends to be relatively safe against disintegration by civil war or political *coup.*[9]

The sources of the bureaucratic state are, to a degree, quite familiar. In the widely reprinted section on bureaucracy from *Economy and Society* (1968:956–1005), Weber outlines the prerequisites: literate administrators, a technology of long-distance transportation and communication, writing and record-keeping materials, monetary coinage. The extent to which these could be put into effect, however, depended on a number of other factors. Geographical conditions such as easy transportation in river valleys, or favorable situations for state-controlled irrigation (1961:237), fostered bureaucratic centralization, as did intense military competition among adjacant heartlands. Types of weapons which are centrally (rather than individually supplied) also favor bureaucratization. If such conditions make central control easy, however, bureaucratization need not proceed very deeply, and the society may be ruled by a thin stratum of officials above a local structure which remains patrimonial. In China, for example, this superficial bureaucratization constituted a long-term obstacle to capitalism, as it froze the economy under the patrimonial control of local clans.

The most thorough bureaucratization, as well as that uniquely favorable to capitalism, is that which incorporates a formalistic legal code based on citizenship. Citizenship meant, first of all, membership in a city; by extension, membership in a state and hence holder of political rights within it. This was an alien concept throughout most of history. In the patrimonial state, political office was a form of private property or personal delegation, and even in most premodern quasi-bureaucratic states the populace at large was only subject to the state, not holders of rights within it. The latter condition arose only in the West. In both Mediterranean antiquity and the European Middle Ages, cities came under the control of brotherhoods of warriors banded together for mutual protection. Such cities had their own laws and courts, administered by the citizens themselves, all of whom stood under it in relation of formal equality. Such citizenship rights remained historically significant after the original civic forms changed or disappeared. The formal rights and legal procedures originally applied only to a local elite, but when cities were incorporated into large-scale bureaucratic states, they provided the basis for a much more widely inclusive system of adjudication. This was the case when Rome, originally one of these military-fraternity cities, became an empire and, again, in the Middle Ages, when cities in alliance with kings lost their independence but contributed their legal structures to the larger states.[10]

---

[9] The main exception is that revolutions can occur after the military breakdown of the state itself due to foreign wars. But historical instances of these have occurred mainly in states which have been only partially bureaucratized. (See Skocpol, 1979.)

Nearing the end of our chain of causality, we ask: What factors enabled this distinctive type of city to arise in the West? Weber gives two conditions: one military, the other religious.

The military condition is that in the West the city consisted of "an organization of those economically competent to bear arms, to equip and train themselves" (1961:237). This was the case in the formative period of the ancient Greek and Italian cities and, again, in the medieval cities with their disciplined infantries fielded by the guilds. In both cases, the money power of the cities bolstered their military power and, hence, democratization and concomitant legal citizenship. In the Orient and in ancient Egypt, on the contrary, the military princes with their armies were older than the cities and, hence, legally independent cities did not arise; Weber attributed this pattern to the impetus to early centralization given by irrigation.

The second condition is that in the East, magical taboos prevented the organization of military alliances among strangers and, hence, did not allow formation of independent cities. In India, for example, the ritual exclusion of castes had this effect. More generally, in Asia and the Middle East, the traditional priests held monopolies over communion with the gods, whereas in Western antiquity it was the officials of the city who themselves performed the rites (1961:238). In the one case, the boundaries of religious communion reinforced preexisting group divisions; in the other, religious boundaries were an explicit political tool by which civic alliances could be established and enlarged. It is at this point that the two main lines of Weber's chain of causality converge.

We have been tracing the causal links behind the emergence of the rational/legal state, which is one of the two great intermediate conditions of the emergence of an open market economy. The other great intermediate condition (noted earlier) is an economic ethic which breaks the barrier between internal and external economies. Now we see that the religious factors that produced the citizenship revolution and those that produced the economic ethic are essentially the same.

Our last question, then, is: What brought about this religious transformation? Weber gives a series of reasons, each intensifying the effects of the last (1961:238). Ethical prophecy within ancient Judaism was important, even though it did not break down ritual barriers between Jews and Gentiles, because it established a tradition of hostility to magic, the main ethos within which barriers flourished. The transformation of Christianity from a Jewish sect into a proselytizing universal religion gave this tradition widespread currency, while the pentacostal spirit of Christian proselytization set aside the ritual barriers among clans and tribes, which still characterized the ancient Hellenistic cities to some degree. The Judeo-Christian innovations are not the whole story, however; the earlier development of Greek religion into the civic cults had already done much to make universalistic legal membership possible.

The religious factors, as we have seen, entwine with political ones, and their influence in the direction of legal citizenship and upon an economic ethic have fluctuated historically. There is no steady nor inevitable trend toward increasing rationalization of these spheres, but Western history does contain a series of episodes which happen to have built up these effects at particular points in time so that, eventually, a whole new economic dynamic was unleashed. On the political side, the Christian cities of the Middle Ages, drawing upon the institutional legacies of the ancient world, were able to establish religiously sworn confraternities which reestablished a legal system based on citizenship. A second political factor was fostered by religion: the Christian church provided the literate administrators, the educational system, and the example of its own bureaucratic organization as bases upon which the bureaucratic states of the West could emerge. And, on the strictly motivational side, the development of European Christianity gave a decisive ethical push toward rationalized capitalism.

---

[10] Contractual forms of feudalism also contributed somewhat to legal citizenship. Weber neglected this in the *General Economic History*, but considered it in *Economy and Society* (1968:1101). The earlier preconditions (military and religious) for contractual feudalism and for independent cities, however, are essentially the same.

Here, at last, we seem to touch base with Weber's original Protestant Ethic thesis. But in the mature Weber, the thesis is greatly transformed. Protestantism is only the last intensification of one of the chains of factors leading to rational capitalism. Moreover, its effect now is conceived to be largely negative, in the sense that it removes one of the last institutional obstacles diverting the motivational impetus of Christianity away from economic rationalization. For, in medieval Christianity, the methodical, disciplined organization of life was epitomized by the monastic communities.[11] Although the monasteries contributed to economic development by rationalizing agriculture and promoting their own industries, Weber generally saw them as obstacles to the full capitalist development of the secular economy. As long as the strongest religious motivation was siphoned off for essentially otherworldly ends, capitalism in general could not take off (1961:267–9). Hence, the Reformation was most significant because it abolished the monasteries. The most advanced section of the economy would, henceforth, be secular. Moreover, the highest ethics of a religious life could no longer be confined to monks but had to apply to ordinary citizens living in the world. Calvinism and the other voluntary sects were the most intense version of this motivation, not because of the idea of Predestination (which no longer receives any mention in Weber's last text) but only because they required a specific religious calling for admission into their ranks, rather than automatic and compulsory membership in the politically more conservative churches. Weber's (1961: 269–70) last word on the subject of Protestantism was simply this:

> The development of the concept of the calling quickly gave to the modern entrepreneur a fabulously clear conscience—and also industrious workers; he gave to his employees as the wages of their ascetic devotion to the calling and of co-operation in his ruthless exploitation of them through capitalism the prospect of eternal salvation, which in an age when ecclesiastical discipline took control of the whole of life to an extent inconceivable to us now, represented a reality quite different from any it has today. The Catholic and Lutheran churches also recognized and practiced ecclesiastical discipline. But in the Protestant ascetic communities admission to the Lord's Supper was conditioned on ethical fitness, which again was identified with business honor, while into the content of one's faith no one inquired. Such a powerful, unconsciously refined organization for the production of capitalistic individuals has never existed in any other church or religion.

WEBER'S GENERAL THEORY OF HISTORY

Is there an overall pattern in Weber's argument? It is not a picture of a linear trend toward ever-increasing rationality. Nor is it an evolutionary model of natural selection, in the sense of random selection of the more advanced forms, accumulating through a series of stages. For Weber's constant theme is that the *pattern of relations among the various factors* is crucial in determining their effect upon economic rationalization. Any one factor occurring by itself tends to have opposite effects, overall, to those which it has in combination with the other factors.

---

[11] Weber did not live to write his planned volume on medieval Christianity. If he had, I believe he would have found that the High Middle Ages were the most significant institutional turning point of all on the road to the capitalist takeoff. His commitment to the vestiges of his Protestantism argument may have kept him from recognizing this earlier. I will deal with this point in a subsequent article, "The Weberian Revolution of the High Middle Ages."

For example, self-supplied military coalitions produce civic organizations and legal systems which are favorable to capitalism. But if the self-armed civic groups are too strong, the result is a series of guild monopolies which stifle capitalism by overcontrolling markets. Cities, on the other hand, have to be balanced by the bureaucratic state. But when the state is too strong by itself, it, too, tends to stifle capitalism. This can happen by bolstering the immobility of labor (as in the case of "the second serfdom" produced in Russia and eastern Europe as absolutist states developed in the seventeenth and eighteenth centuries); or by directly controlling the division of labor by forced contributions instead of allowing a market to develop. In the areas of the world where bureaucratization was relatively easy, as in ancient Egypt or China, or the Byzantine Empire, the unrestrained power of the state stereotyped economic life and did not allow the dynamics of capitalism to unfold.

The same is true of the religious variables. The creation of the great world religions, with their universalism and their specialized priesthoods, was crucial for the possibility of breaking the ritual barriers among localized groups, with all the consequences this might have for subsequent developments. But, in the absence of other factors, this could actually bolster the obstacles to capitalism. This happened in India, where the development of Hinduism fostered the caste system; the universalistic religion set an external seal upon the lineup of particularistic groups that happened to exist at the time. Even in Christianity, where moral prophecy had a much more barrier-breaking and world-transforming effect, the Church (in the period when it was predominant) created another obstacle against its capitalist implications. This was the period of the High Middle Ages in Europe, when monasticism proliferated and, thus, channeled all the energy of religious motivation into a specialized role and away from the economic concerns of ordinary life.[12]

Weber saw the rise of large-scale capitalism, then, as the result of a series of combinations of conditions which had to occur together. This makes world history look like the result of configurations of events so rare as to appear accidental. Weber's position might well be characterized as historicist, in the sense of seeing history as a concatenation of unique events and unrepeatable complexities. Once a crucial conjuncture occurs, its results transform everything else—and not just locally but also in the larger world of competing states. This was true of the great charismatic revelations of the world religions, which shut off China, India, or the West from alternative lines of development as well as determined the ways that states upon these territories would interact with the rest of the world. Similarly, the full-scale capitalist breakthrough itself was a once-only event, radiating outward to transform all other institutions and societies. Hence, the original conditions necessary for the emergence of capitalism were not necessary for its continuation. The original religious ethic could fade, once the calculability of massive economic transactions had become a matter of routine. Hence, late-industrializing states need not follow the route of classic capitalism. In the advanced societies, the skeleton of the economic structure might even be taken over by socialism.

Weber's account of the rise of capitalism, then, is in a sense not a theory at all, in that it is not a set of universal generalizations about economic change. Nevertheless, on a more abstract level, Weber is at least implicitly proposing such a theory. On one level, he may be read as a collection of separate hypotheses about specific processes and their effects.[13] The foregoing caveat about the necessary balance among factors may be incorporated by specifying that the causal variables must operate at a given strength—that is, by turning them into quantitative generalizations specified to a given range of variation.

---

[12] This was also the time when the church took the offensive against incipient capitalism, in the form of pronouncements against usury (Weber, 1968:584–6).

[13] One clearly formulated proposition, for example, is that armies based on coalitions of self-supplied individuals produce citizenship rights. (For a series of such propositions, see Collins, 1975:356–64.)

On a second level, one may say that the fundamental generalizations in Weber's theory of capitalism concern the crucial role of balances and tensions between opposing elements. "All in all," says Weber in a little-known passage (1968:1192–3), "the specific roots of Occidental culture must be sought in the tension and peculiar balance, on the one hand, between office charisma and monasticism, and on the other between the contractual character of the feudal state and the autonomous bureaucratic hierarchy."[14] No one element must predominate if rationalization is to increase. More concretely, since each "element" is composed of real people struggling for precedence, the creation of a calculable, open-market economy depends upon a continuous balance of power among differently organized groups. The formal egalitarianism of the law depends upon balances among competing citizens and among competing jurisdictions. The nondualistic economic ethic of moderated avarice depends upon a compromise between the claims of in-group charity and the vicious circle of out-group rapaciousness.

The capitalist economy depends on this balance. The open-market system is a situation of institutionalized strife. Its essence is struggle, in an expanded version of the Marxian sense, but with the qualification that this could go on continuously, and indeed must, if the system is to survive.[15] Hence, if there is any generalization implicit in Weber's theory applicable to economic history after the initial rise of capitalism, it is this: The possibility for the follower-societies of the non-Western world to acquire the dynamism of industrial capitalism depends on there being a balance among class forces, and among competing political forces and cultural forces as well. In the highly industrialized societies also, the continuation of capitalism depends on continuation of the same conflicts. The victory of any one side would spell the doom of the system. In this respect, as in others, Weber's theory is a conflict theory indeed.

AN ASSESSMENT: WEBER'S CONFRONTATION WITH MARXISM

How valid is Weber's theory? To fully answer this question would require extensive comparative analyses and a good deal of explication of principles on different levels of abstraction. These tasks are beyond the scope of any one paper. What I can present is a confrontation between Weber's theory and the one rival theory of capitalism which claims a comparable degree of historical and theoretical comprehensiveness, Marxism. This is especially appropriate because Weber himself devoted a great deal of attention in the *General Economic History* to the points at which his analysis impinges on Marxist theories.

The book begins and ends on Marxian themes. The first chapter deals with the question of primitive agrarian communism. Characteristically, Weber finds it to be only one variant of primitive agriculture; where it does exist, it is usually the result of fiscal organization imposed from above (1961:21–36). The closing words of the book speak of the threat of working class revolution which appears once capitalism matures and work discipline loses its religious legitimation (1961:270). In between, there are numerous references to Marxism, far more than in any other of Weber's works. His attitude is critically respectful, as in his comment on the Engels-Bebel theory of the origins of the family: "although it is untenable in detail it forms, taken as a whole, a valuable contribution to the solution of the problem. Here again is the old truth exemplified that an ingenious error is more fruitful for science than stupid accuracy." (1961:40)[16]

---

[14] In other words, the main features of the West depend on a tension between the routinization of religious charisma in the church and the participatory communities of monks, and on a tension between the democratizing tendencies of self-supplied armies and the centralized bureaucratic state. These give us Weber's two great intermediate factors, a nondualistic religious ethic and calculable law, respectively.

[15] . . . . the formal rationality of money calculation is dependent on certain quite specific substantive conditions. Those which are of a particular sociological importance for present purposes are the following: (1) Market struggle of economic units which are at least relatively autonomous. Money prices are the product of conflicts of interest and of compromises; they thus result from power constellations. Money is not a mere "voucher for unspecified utilities," which could be altered at will without any fundamental effect on the character of the price system as a struggle of man against man. "Money" is, rather, primarily a weapon in this struggle, and prices are expressions of the struggle; they are instruments of calculation only as estimated quantifications of relative chances in this struggle of interests (Weber, 1968:107–8).

Weber's intellectual maturity coincides with a period of high-level debate in Germany and Austria between Marxian and non-Marxian economists. In the years between 1885 and 1920 appeared Engels's editions of the later volumes of *Capital*, as well as the principal works of Kautsky, Hilferding, and Luxemburg. On the other side, Sombart, Bortkiewitz, and Tugan-Baranowski provided what they considered to be revisions in the spirit of Marxian economics, while Böhm-Bawerk (1898) and Schumpeter (1954) launched explicit efforts to shore up the weaknesses of neoclassical economics vis-à-vis Marxism, and attacked the technical weaknesses of Marxian theory.[17] This period was in many ways the high-water mark in political economy for an atmosphere of balanced debate is beneficial for intellectual advance. Weber in particular was concerned to meet the Marxian challenge on its own grounds, leaving out nothing that must be conceded, but also turning up whatever factors the Marxists left out. Moreover, the German Marxists had suddenly become stronger with the end of the World War and the downfall of the German monarchy. Weber delivered his lectures in Munich just after the short-lived Communist commune of 1919, and his lecture room contained many radical students. It is not surprising that Weber was so much more explicitly concerned with Marxism in his last work than in the religious studies he published while the war was going on.

Weber had one great advantage over the Marxists. The discipline of historical scholarship reached its maturity around the end of the nineteenth century. Not only had political and military history reached a high degree of comprehensiveness and accuracy, but so had the history of law, religion, and economic institutions not only for Europe and the ancient Mediterranean but for the Orient as well. The historical researches of the twentieth century have not brought to light any great body of facts about the past that has radically changed our view of world history since Weber's day. Weber was perhaps the first great master of the major institutional facts of world history. By contrast, Marx, pursuing his assiduous researches in the 1840s and 50s, had much narrower materials at his disposal (Hobsbawm 1964:20–7). The histories of India, China, Japan, or Islam had scarcely begun to be available; the permeation of the ancient Greco-Roman world by religious institutions was only beginning to be analyzed; and the complex civilization of the European High Middle Ages was hidden beneath what Marx considered the "feudal rubbish" of the *Ancien Regime* of the eighteenth century. Marx wrote before the great coming-of-age of historical scholarship; Weber, just as it reached its peak. Weber thus represents for us the first and in many ways still the only effort to make a truly informed comparative analysis of major historical developments.

It should be borne in mind that Marx and most of his followers have devoted their attention primarily to showing the dynamics of capitalism, not to the preconditions for its emergence. Weber's concerns were almost entirely the reverse. Hence, it is possible that the two analyses could be complementary, Marx's taking up where Weber's leaves off. Only in the 1970s have there been efforts comparable to Weber's from within the Marxian tradition, notably that of Wallerstein (1974). Interestingly enough, Weber anticipated Wallerstein's major points in the *General Economic History*. On the other side, Wallerstein's revision of Marxism is in many ways a movement toward a more Weberian mode of analysis, stressing the importance of external relations among states.

---

[16] Weber goes on to say, "A criticism of the theory leads to consideration first of the evolution of prostitution, in which connection, it goes without saying, no ethical evaluation is involved." There follows (1961:40–53) a brilliant outline of a theory of the organization of the family as one set of variants on sexual property relations, in which material transactions and appropriations are fundamentally involved. Later versions of this line of theory are found in Levi-Strauss (1968), and in Collins (1975:228–59).

[17] Thus, Böhm-Bawerk (1898) and Schumpeter (1954) developed a previously missing link in classical and neoclassical economics, a theory of capitalist profits. This they based on time-lags in the competitive process and resulting time-preference among investment returns, displacing the Marxian theory of profit based on the exploitation of labor. Böhm-Bawerk also made an analysis of socialist economies. He regarded these as possible *politically* (as did Schumpeter and Weber), but denied that production would be organized differently than in capitalism. Socialism could affect only the distribution of capitalist profits among the populace. For the economic thought of this period, see Schumpeter (1954:800–20, 843–55, 877–85) and Sweezy (1942:190–213).

The classical Marxian model of the preconditions for capitalism covers only a few points (Marx, 1967: I, 336–70, 713–64; II, 323–37, 593–613; 1973: 459–514). Some of these are a subset of Weber's model, while two of them are distinctive to Marx. Weber and Marx both stressed that capitalism requires a pool of formally free but economically propertyless labor; the sale of all factors of production on the market; and the concentration of all factors in the hands of capitalist entrepreneurs. Marx did not see the importance of the *calculable* aspect of technology; at times, he seemed to make the sheer productive power of technology the central moving force in economic changes, while at others, he downplayed this as part of a larger economic system—much in the way Weber did. Unlike Weber, Marx gave no causal importance at all to calculable law, nor did he see the earlier links in Weber's causal chain: economic ethics, citizenship, bureaucratization, and their antecedents.[18]

The uniqueness of Marx's discussion is in two factors: primitive accumulation, and revolution. About the latter, Marx had surprisingly little to say beyond the dramatic imagery of revolution breaking the bonds imposed by the property system upon the growing engines of production (Marx, 1959: 43–4). Primitive accumulation takes up nearly the whole of his historical discussion. It means the accumulation of enough raw materials, tools, and food for laborers to live on before subsequent production was completed; hence, it is the quantitative prerequisite for any takeoff into expanded economic production. Such accumulation took place historically in two ways. One was by the expropriation of peasants from their land, which simultaneously concentrated wealth in the hands of the capitalists who received the lands and required the expropriated masses to sell their labor on the market. The other means of primitive accumulation was by usury and merchants' capital. Marx downplayed the importance of monetary factors by themselves, as they operated only in the realm of circulation and did nothing to productive relations; but he did assert that the growth of money capital furthered the dissolution of the feudal economy once it was already under way (1967:III, 596–7).

Of these two factors, Weber says almost nothing explicitly about primitive accumulation. However, the entire earlier sections of the *General Economic History* (1961:21–203) deal with the various forms of appropriation of material and financial means, which have made up, among other things, the capitalism that has been omnipresent throughout history, although not in a rationalized form. The idea that there must be a specific accumulation of surplus for the purpose of a capitalist takeoff, I suspect, is one that Weber would reject. The assumption ought to be subjected to proof. After all, agrarian societies already have the most extreme concentration of wealth at the top of the social hierarchy of any type of society in world history (Lenski, 1966); the industrial takeoff need only have been fueled by a shift in the use of this wealth, not by a further extraction process. As Weber understood, and as subsequent research has shown, capitalists do not have to rise "from below," having amassed their own wealth; it has been far more typical for the aristocracy themselves to go into capitalist production (Stone, 1965; Moore, 1966).[19]

---

[18] Marx (1973:459–514) gave a very general outline of early forms of property as based on family and tribal membership, and he recognized that the ancient cities were military coalitions. He missed the central organizing role of religion in these developments, and failed to see the crucial effect of the revolutions within the ancient cities upon the uniquely Western legal tradition. For Marx, the rise of cities simply meant the growing separation of town and country, an instance of dialectical antithesis, and of the progress of the division of labor (1967:I, 352). For the period immediately preceding the capitalist takeoff, Marx noted that the state had hastened the transition from feudalism to capitalism by creating public finance and conquering foreign markets. These effects Marx subsumed under his concept of "primitive accumulation."

Weber is somewhat more sympathetic to the importance of revolutions. Perhaps the final conditions for the capitalist takeoff in England were the revolutions of 1640 and 1688. These put the state under the control of political groups favorable to capitalism, thus fulfilling the condition of keeping markets and finances free of "irrational" and predatory state policies. Of more fundamental institutional consequence were the revolutions within the cities of ancient Greece and of medieval Italy. The latter, Weber lists among "the five great revolutions that decided the destiny of the occident" (1951:62).[20] For it was the uprising of the plebeians which replaced the charismatic law of the older patrician class with the universalistic and "rationally instituted" law upon which so much of the institutional development of capitalism was to depend (Weber, 1968:1312–3, 1325). In effect, this was a revolution in a system of property, but not in the gross sense of a replacement of one form of appropriation with another. For Weber, a system of property is a complex of daily actions—above all, the making of transfers and contracts and the adjudication of disputes. Hence, political revolutions are most crucial where they set the pattern for ongoing legal actions in a highly calculable form, with all the consequences noted above.

Wallerstein's (1974) theory, as developed in volume I, emphasizes two conditions in the origins of capitalism. One is the influx of bullion from the European colonies, which caused the price inflation of the 16th century. During this period, wages remained approximately constant. The gap between prices and wages constituted a vast extraction of surplus which could be invested in expanding capitalist enterprises (Wallerstein, 1974:77–84).[21] This is Wallerstein's version of the primitive accumulation factor.

Wallerstein's (1974:348) second condition also emerges from the international situation. "[C]apitalism as an economic system is based on the fact that economic factors operate within an arena larger than that which any political entity can totally control. This gives capitalists a freedom of maneuver that is structurally based." He (1974:355) goes on to say that the different states must be of different strengths, so that not all states "would be in the position of blocking the effective operation of transnational economic entities whose locus were in another state." Capitalists in effect must have opportunities to shift their grounds among varied political climates to wherever the situation is most favorable.

Weber (1961:259) was generally aware of both conditions. Regarding the effects of gold and silver influx, however, he was largely unfavorable.

> It is certainly true that in a given situation an increase in the supply of precious metals may give rise to price revolutions, such as that which took place after 1530 in Europe, and when other favorable conditions are present, as when a certain form of labor organization is in the process of development, the progress may be stimulated by the fact that large stocks of cash come into the hands of certain groups. But the case of India proves that such an importation of metal will not alone bring about capitalism. In India in the period of the Roman power, an enormous mass of precious metal—some twenty-five million *sestertii* annually—came in exchange for domestic goods, but this inflow gave rise to commercial capitalism only to a slight extent. The greater part of this precious metal disappeared into the hoards of the rajahs in-

---

[19] Weber also anticipated Barrington Moore's (1966) theory of the political consequences of different property modes in the commercialization of agriculture (1961:81–94).

[20] The others were "the Netherland revolution of the sixteenth century, the English revolution of the seventeenth century, and the American and French revolutions of the eighteenth century."

[21] To this, Wallerstein adds the argument that surplus is further extracted by coerced labor on the periphery, to be consumed in the core, where however (somewhat contrary to the point about the price revolution) labor is well enough paid to constitute a potential consumers' market for capitalist production.

> stead of being converted into cash and applied in the establishment of enterprises of a rational capitalistic character. This fact proves that it depends entirely upon the nature of the labor system what tendency will result from an inflow of precious metal.

In another passage, Weber (1961:231) does say that the price revolution of the sixteenth and seventeenth centuries "provided a powerful lever for the specifically capitalistic tendencies of seeking profit through cheapening production and lowering the price." This came about for industrial (but not agricultural) products, because the quickened economic tempo put on pressures toward further rationalizing economic relations and inventing cheaper technologies of production. Weber thus gives the influx of precious metals a place as a contributory factor, though apparently not an indispensable one, *within* the framework of economic institutions which had already appeared in Europe at the time.[22]

Weber (1961:249) largely agrees, however, with Wallerstein's argument about the international character of capitalism. Modern cities, he points out,

> came under the power of competing national states in a condition of perpetual struggle for power in peace or war. This competitive struggle created the largest opportunities for modern Western capitalism. The separate states had to compete for mobile capital, which dictated to them the conditions under which it would assist them to power. Out of this alliance of the state with capital, dictated by necessity, arose the national citizen class, the bourgeoisie in the modern sense of the word. Hence it is the closed national state which afforded to capitalism its chance for development—and as long as the national state does not give place to a world empire capitalism will also endure.

Here the coincidence with Wallerstein is remarkable. Weber does not emphasize the contours of Wallerstein's world system, with its tiers of core, semiperiphery, and periphery, but Weber does show the central importance of mobile capital among militarily competing states, and he gives a more specific analysis than Wallerstein of the mechanism by which this is transformed into an advantage for capitalism.

In general, there is considerable convergence, as well as complementarity, between Weber's last theory of the origins of capitalism, and the mature Marxian theory which is only now emerging. Weber largely rejects Marxian theories of primitive accumulation, or at least relegates them to minor factors. On the other side, Wallerstein, as well as modern Marxism in general, has moved the state into the center of the analysis. Weber had already gone much further in that direction, so that the main Weberian criticism of the Marxian tradition, even in its present form, is that it does not yet recognize the set of institutional forms, especially as grounded in the legal system, upon which capitalism has rested.

For Weber, the state and the legal system are by no means a superstructure of ideas determining the material organization of society. Rather, his theory of the development of the state is to a considerable extent an analogy to the Marxian theory of the economy. The key factor is the form of appropriation of the material conditions of domination. We have seen the significance of the organization of weapons for Weber's chain of causes of capitalism. In this connection, Weber (1961:237) remarks:

> Whether the military organization is based on the principle of self-equipment or on that of military equipment by an overlord who furnishes horses, arms and provisions, is a distinction quite as fundamental for social history as the question whether the means of economic production are the property of the

---

[22] Weber's (1961:223) comment on the economic benefits of the colonies is even more negative.

> This accumulation of wealth brought about through colonial trade has been of little significance for the development of modern capitalism—a fact which must be emphasized in opposition to Werner Sombart. It is true that the colonial trade made possible the accumulation of wealth to an enormous extent, but this did not further the specifically occidental form of the organization of labor, since colonial trade itself rested on the principle of exploitation and not that of securing an income through market operations. Furthermore, we know that in Bengal for example, the English garrison cost five times as much as the money value of all goods carried thither. It follows that the markets for domestic industry furnished by the colonies under the conditions of the time were relatively unimportant, and that the main profit was derived from the transport business.

> worker or of a capitalistic entrepreneur . . . [T]he army equipped by the war lord, and the separation of the soldier from the paraphernalia of war, [is] in a way analogous to the separation of the worker from the means of production. . . ."

Similarly, state bureaucracy depends upon a set of material conditions, and upon the separation of the administrator from treating the office and its incomes as private property (1968:980–3). Weber diverges from the Marxian analogy by being a more thoroughgoing conflict theorist. As we have seen, and as the quotation given above on the international basis of capitalism bears out, for Weber the conditions of rationalized organization, in political and economic spheres alike, depend upon a continuous open struggle.[23]

The main disagreements between Marx and Weber have less to do with the origins of capitalism than with its future. Weber thought that capitalism could endure indefinitely as an economic system, although political factors could bring it down. As we have seen, he thought that the disappearance of religious legitimation in mature capitalism opened the way for workers to express their discontents in the form of a political movement for socialism. Ironically, it is the rationalized world view promoted by the underlying conditions of capitalism that gave birth to rational socialism, a doctrine that proclaims that the social order itself, rather than the gods, is to blame for economic distress; and that having been deliberately instituted, that order is capable of being consciously changed (1961:217–8). For Weber, however, economic crises may be endemic to modern capitalism, but they are not caused by a fundamental contradiction in it, nor is there any necessary tendency for them to worsen toward an ultimate breakdown. He attributes crises to overspeculation and the resulting overproduction of producers' (but not consumers') goods (1961:217). To decide who is right on these points requires further consideration than can be given here.

CONCLUSION

Weber's last theory is still today the only comprehensive theory of the origins of capitalism. It is virtually alone in accounting for the emergence of the full range of institutional and motivational conditions for large-scale, world-transforming capitalism. Even so, it is incomplete. It needs to be supplemented by a theory of the operation of mature capitalism, and of its possible demise. And even on the home territory of Weber's theory, there remain to be carried out the comprehensive tests that would provide adequate proof. But sociological science, like any other, advances by successive approximations. The theory expressed in Weber's *General Economic History* constitutes a base line from which subsequent investigations should depart.

IMMIGRATION AND THE EXPANSION OF SCHOOLING IN THE UNITED STATES, 1890–1970*

JOHN H. RALPH
University of Delaware

RICHARD RUBINSON
Johns Hopkins University

American Sociological Review 1980, Vol. 45 (December):943–954

Our research analyzes the effects of immigration on the rate of growth of educational expansion in the United States from 1890 to 1970. Previous studies have shown that the presence of nativist, Protestant-millenial groups was associated with the early expansion of public primary enrollments. Immigrant groups provide an important contrast to such groups, and several interpretive histories of United States education stress the relationship between immigration and schooling. Using aggregate, time-series analyses, we find that: (1) immigration decreased the rate of growth of public primary and secondary enrollments between 1890 and 1924; (2) immigration increased the rate of growth of private primary and secondary enrollments during this period; (3) immigration increased the rate of growth of public primary and secondary enrollments between 1925 and 1970; and (4) immigration decreased the rate of growth of private primary and secondary enrollments during the period. These findings show that the effect of immigration on the aggregate rate of growth of schooling has varied as a function of the character of the immigrants themselves.

Formally organized education has become such a central institution for both national and individual development that we often assume that the explanation for its tremendous growth is not problematic. Government supports education because of its assumed importance to national goals, and individuals demand education because of its assumed importance to personal mobility. Educational expansion in today's world seems to be an almost self-generating process.

For example, an extensive cross-national study of educational expansion by Meyer et al. (1977) found that the rapid worldwide growth of enrollments from 1950 to 1970 could be explained primarily as a function of the available school-age population to be educated and by the level of enrollments in 1950. This study concludes that education has become of such importance that it now expands independently of the constraints and stimuli that economic, political, and social structures must have provided in previous times.

The United States is certainly one country where education is seen as fundamental to national purposes and where individuals and groups constantly demand more education. But if this characterization is true today, this has not always been the case. For during most of the period of educational expansion in the United States, the links between education and national development and between education and mobility were not assumed. In order to understand the growth of educational enrollments, then, we must analyze the long-term historical conditions that created the presently high levels of education. The purpose of this paper is to study one social factor that has often been suggested as important to educational expansion in the United States, the role of immigration. We want to investigate how the influx of immigration has affected the growth of educational enrollments.

While there are many interpretations of the rise of education in the United States, there are few systematic, long-term national studies. A recent study by Meyer et al. (1979) shows that it is important to separate the formalization of schooling—the rise of bureaucratic,

Keely, John Meyer, and Ludwig-Mosberg for critical readings of earlier versions. We also thank W. Vance Grant for making data available to us.

state-funded, and professionally managed education—from the creation and spread of enrollments. Using state-level data in a series of seven cross-sectional analyses every ten years from 1870 to 1930, the study finds that indicators of urban industrialization have consistently large effects on two measures of educational formalization, the average expenditures per pupil and the length of the school term. But these factors do not affect the measure of the spread of education, the level of public primary-school enrollments. Rather, the analyses show that two indicators of what they refer to as nation-building social movements, a measure of Republican party strength and a measure of evangelical Protestantism, increase the level of public primary-school enrollments. Their argument is that the expansion of schooling reflected the widespread ideology of the traditional Protestant-millenial groups in the United States. Local public education was a mechanism for organizing local community. Their study finds that the greater the presence in a state of such groups, the higher the total level of public primary enrollments. They argue that not only was it the children of these groups who went to school but that the greater the presence of these groups, the greater the total level of enrollment.

If the presence of such traditional groups as these had the consequence of increasing educational levels, then it is also necessary to study how the presence of other major groups affected the growth of enrollments. In the United States, immigrant groups provide an important contrast, for such groups were often viewed as fundamentally opposite to the traditional, nativist groups (Higham, 1974).

The assimilation of the immigrant through schooling has been a prominent concern in the interpretive histories of public education (Bowles and Gintis, 1976; Butts, 1978; Everhart, 1977; Greer, 1972). Recent revisionist histories of education suggest that public schooling was imposed on immigrant groups to acculturate them to the dominant economic, political, and social patterns of the country. Such studies simultaneously emphasize the resistance by these groups to attempts at imposition (Collins, 1976).

Census data reported in Table 1 show that as early as 1900 the rates of school enrollment for children aged six to sixteen were remarkably similar for both the children of immigrants and of native-born fathers. In addition, despite the concerns at that time over the problems of educating immigrants, data from this period summarized in Table 2 show that rates of school retardation were almost the same for the children of native-born and of foreign-born fathers, and even for foreign-born students. Thus, *rates* of attendance and of retardation were similar for the children of immigrants and of native-born fathers.

But to know that the rates of attendance were similar for these groups does not tell us what the consequences of immigration were for the general rate of educational enrollment. The influx of immigration may have caused an overall increase in the rate of growth of school enrollments if it initiated a status competition process in which other groups increased their rates of school enrollment to preserve their status distinctions over immigrants (Collins, 1971). Immigration may also have increased rates of school enrollments for everyone if the perceived threat posed by immigration to dominant cultural values caused local authorities to expand schooling as a mechanism of cultural solidarity. Immigration may also have decreased the rate of growth of *public* schooling and increased the rate of growth of *private* schooling either because immigrants chose or were subtly channeled to private schools, or because nonimmigrant groups sought to protect their status through private schooling. The effects of immigration on the rate of schooling involved social forces that may have altered

Table 1. Percent of Children 6 and under 16 at School by Nativity

Parentage Subgroup	% at School
Native-born Father	84.6
Foreign-born Father	84.2
Foreign-born Student	83.3

behaviors and expectations for a large number of groups. To answer the question of how immigration affected the growth of schooling, we need to study the aggregate relationship between immigration and enrollment rates. The aggregate, national analyses we present here cannot tell us why immigration affected the growth of schooling, but they can tell us if it did and how it affected that growth. Such analyses as these can also point to fruitful directions for other studies and, combined with more micro studies, can lead toward the development of an explanation for the growth of schooling in the United States.

Immigration, Public Policy, and Popular Reaction

The amount and character of international migration to the United States has always been subject to political policy. The United States initially had an open immigration policy, and after the Civil War the immigrant population rapidly increased. The number of immigrants declined during the depression of the 1890s but rose rapidly until World War I. During the war immigration declined, but public concern over the prospect of large-scale immigration in the 1920s led to the National Origins Quota Acts. Until 1921, the federal government had only restricted the immigration of Orientals and "defective individuals" such as prostitutes and criminals. By 1924, a quota system based on the individual's national origin was established, shifting the character of immigration from those coming from eastern, southern and central Europe to those from northern and eastern Europe.

Table 3 shows the changes in immigration by European regions. Until 1890, immigrants from northern and western Europe were the overwhelmingly predominant groups. The peak of this immigration occurred from 1881 to 1890 after 30 years in which this immigration exceeded 2,000,000 per decade. This amount was 100 times greater than the number of immigrants from eastern, central, and southern Europe. Between 1901 and 1910, the situation changed dramatically. During this decade the number of immigrants from eastern, central, and southern Europe was twice as large as the number from northern and eastern Europe. Furthermore, the total number of immigrants during the decade was more than double the level of the previous decade. Figure 1 shows the variation in total number of immigrants by year. After 1924 there was a decline in both the magnitude and variation of immigration. It is important for our analyses of schooling to highlight this change.

It was probably not the number of immigrants that provoked widespread public concern, but the differences in the social characteristics of these new immigrants. Professor Cubberly, a noted educational spokesman at Stanford, argued that the new immigrant was different and needed to be Americanized (Cubberly, 1909:15–6). These new immigrants were different. They came from different countries, their native languages were unfamiliar, and they were predominantly Catholic. The public clamor over these groups was a reaction to these social characteristics, but also a reaction to political changes. During this period, labor unions grew from 447,000 in 1897 to over two million by 1904 (U.S. Census, 1976). Labor strikes were becoming more frequent. In 1911 socialist party candidates were elected mayors in 73 municipalities, and socialist ideas became prominent in unions and local political groups. The political strength of socialism at the ballot box peaked in 1918, but strong anticapitalist sentiment and support for mass strikes lasted through the 1920s (Weinstein, 1968). In the public mind, radical politics and recent immigration were closely linked (Higham, 1974).

Table 3. European Immigration by Region: 1819 to 1954

			Regions			
Period	Total[1] Immigration	All Europe	North and West	East and Central	South	Other
Total, 1819 to 1954	40,173	33,764	19,457	8,549	5,715	43

[5] January 1, 1861 to June 30, 1870.

Civic leaders of this period proclaimed their faith in the ability of schools to indoctrinate consensual values and desirable attitudes in the new groups. Good citizenship, they argued, could overcome class politics, and the public school system was to be the agent through which immigrant children would learn American ways (Roberts, 1912). Schooling and the character of immigration became linked during this period.

Revisionist educational histories emphasize the struggle over the imposition of schooling. Bowles and Gintis (1976:175) argue that immigrants did not oppose education, but they did oppose education they could not control. These issues have direct consequences for the relationship between immigration and schooling. During the Progressive Era, the influx of immigration stimulated political, economic, and cultural elites to strengthen public education as an agent of assimilation and stratification. As a consequence, the influx of immigration and the reaction it provoked may have led to an expansion of the overall rate of schooling. But immigrant groups also resisted the imposition of public schooling. Historically, the public schools had been stamped with the character of Protestant values and outlook (Tyack, 1970; Meyer et al., 1979), and one of the prominent features of these new immigrants was their Catholic heritage. After 1900, Greek Orthodox, Roman Catholic, and Lutheran schools flourished in most metropolitan areas (Ravitch, 1978). And Smith (1967) has documented the desire of immigrants to initiate their own educational programs. These considerations imply that the influx of this immigration may have decreased the rate of public school growth and increased the rate of private school growth.

The empirical analyses we now present investigate the relationship between the influx of immigration and the growth of schooling in the United States from 1890 to 1970. These aggregate, national analyses do not distinguish among the several reasons why the rate of schooling was affected by immigration, but they can show us if it was, and how. These analyses investigate the relationships

Figure. 1. Immigration, 1820–1970 (in thousands)

between immigration and the growth of primary and secondary school enrollments, both public and private, distinguishing between the periods 1890 to 1924 and 1924 to 1970.

Model Specification and Data

The analyses. consist of a series of time-series regression analyses using annual national enrollment and immigration figures. In order to estimate the effects of immigration on enrollments, we need to develop a basic model of the growth of enrollments within which the effects of immigration can be studied. Following the work of Nielsen and Hannan (1977) and of Meyer et al. (1977), the basic model for the growth of primary education is as follows:

$$\begin{aligned} &P_t - P_{\Delta t} = \\ &x + B_1 P_{\Delta t}(\mathrm{PRIPOP}_{\Delta t} - P_{\Delta t}) \\ &+ B_2 \mathrm{PRIPOP}_{\Delta t} \\ &+ B_3 \mathrm{IMM}_{\Delta t} + e, \qquad (1) \end{aligned}$$

where: P_t and $P_{\Delta t}$ = primary-school enrollment at time t and an earlier time Δt; PRIPOP = primary age-group population; and IMM = number of immigrants.

This model is based on the following ideas. As an institution, schooling is to some extent self-perpetuating. Once in school, we would not expect parents to withdraw students from school or government agencies to totally withdraw support. Therefore, the maintenance of a constant number of students in school between time t and some previous time Δt is not problematic. What is to be explained is the change in the number of students in school. The dependent variable, then, is the difference in the number of students between time t and Δt. The growth of enrollments, as in most growth processes, is not linear. The rate of educational expansion begins slowly at low levels of enrollment, increases rapidly at middle levels of enrollment, and slows down as enrollments approach their ceilings of the total eligible age-group population (OECD, 1971). The term $P_{\Delta t}(\mathrm{PRIPOP}_{\Delta t} - P_{\Delta t})$ models this S-curve process of growth. This term says that the growth of enrollments in primary school is a function both of the earlier number of people in school, $P_{\Delta t}$, and of the number of people in the eligible age-group not in school, $PRIPOP_{\Delta t} - P_{\Delta t}$. The eligible age-group population at the earlier time, $PRIPOP_{\Delta t}$, is also included in the model to control for the effect of changes in the size of the age-group population of changes in the number of students enrolled. These terms in Equation 1, then, model the organizational and demographic factors affecting the growth of school enrollments. The effect of immigration and other variables is analyzed within the context of this model. The model used for secondary education is the same except that since the number of students enrolled in secondary education depends on the number in primary education, a term representing this succession process is included.

The analyses consist of a number of time-series regressions on annual, national data for primary and secondary education, both public and private, from 1890 to 1970. School enrollment data are from the *Biennial Survey of Education* (called the *Annual Report of the United States Commissioner of Education* until 1916).[1] Data for the age-group population are from *Current Population Reports* (United States Bureau of the Census, 1974). For the primary age-group population we use the population 5 to 13 years of age, and for the secondary age-group population we use the population 14 to 17 years of age.[2] The number of immigrants per year is from the *Historical Statistics of the United States* (1976). Since the effects of immigration on enrollments necessarily imply some time period for their operation, we use both 5- and 10-year time lags (Δt).[3]

The Growth of Public School Enrollments

We begin by analyzing the effects of immigration on public school enrollments at primary and secondary levels from 1890 to 1970. We divide this time period into two parts, 1890 to 1924 and 1925 to 1970.[4] We analyze these periods separately to take into account the dramatic change in the character of immigration brought about by the National Origins and Quota Acts of 1924.

Table 4 presents the regression estimates and t-scores for public primary and secondary enrollments lagged 5 and 10 years for the period 1890–1924 in the top panel, and the estimates for the period 1925–1970 in the bottom panel. Inspecting the equations for primary enrollment (equations A, B, E, F), we see that both the term modelling the S-curve growth process and the eligible age-group popu-

---

[1] These enrollment figures are from annual national population surveys of schools. The *U.S. Historical States, Colonial Times to 1970* presents these figures for even-numbered years after 1918 (Series 422, 424, 427, 429). The figures for the omitted years were supplied by W. Vance Grant of the United States Office of Education.

[2] In preliminary analysis of the school data, there was a strikingly high proportion of the eligible age-group population enrolled in public primary school as early as 1870. This observation led to a reexamination of the raw data. One conjecture was that the simple calculation of an enrollment rate for schooling (number of pupils enrolled/number of eligible-age individuals) contains a source of bias in the denominator. The bias derives from differential rates of grade-level promotion (the advancement of pupils from one grade-level to the next) that have changed over time. The possibility arises that a significant portion of enrolled students may be older than the range of eligible ages standardized for in the denominator. In this case, the enrollment rate will be biased upward for those historical periods characterized by large amounts of grade level "flunking." We constructed two other enrollment series based on calculations of the number of overage students in primary and secondary school. The new enrollment figures were not substantially changed, at least not to the extent that would "explain away" the high levels of enrollments with which we were initially concerned. Second, preliminary analyses were run using all three sets of enrollment figures, the original data plus the two transformed time-series. The resulting estimated effects of the coefficients also were substantially unchanged. (See Ralph, 1978, for full details.)

[3] The choice of lag periods in which the process by which immigration affects enrollment were selected as five and ten years to allow for both shorter- and longer-term processes. We present both lag periods here as a means to show consistency of the results. It is possible to interpret the five- and ten-year lags as representing different mechanisms for the effects, but we choose not to do so here until the potentially different mechanisms can be theoretically specified.

[4] Equation 1, for a five-year lag, then, specifies that $P_t - P_{\Delta t}$ is primary enrollment in 1894– primary enrollment 1890, primary enrollment 1895– primary enrollment 1891, etc; and that $IMM_{\Delta t}$ is immigration in 1890, 1891, etc. No data overlaps the two time periods of 1890 to 1924 and 1925 to 1970.

D. Secondary Enrollment, 1890–1924, 10-year lag	.3E-2(9.97)	−.5(−2.04)	−.006(−.34)	.92	.64
E. Primary enrollment, 1930–1970, 5-year lag	.8E-4(4.52)	.73(34.6)	.18(2.03)	.99	.92
F. Primary Enrollment, 1930–1970, 10-year lag	.2E-3(10.8)	.78(63.4)	.29(5.4)	.996	.95
G. Secondary Enrollment, 1930–1970, 5-year lag	.17E-3(1.13)	.9(9.37)	−.1(−.93)	.89	.52
H. Secondary Enrollment, 1930–1970, 10-year lag	.4E-3(1.16)	.68(15.2)	.45(5.25)	.96	.69

NOTES: * Table entries are slope, with T-statistics shown in parentheses.

[a] The enrollment variables are constructed as difference terms, 5 years apart in the 5-year lags and 10 years apart in the 10-year lags; e.g., enrollment $_{1896}$ − enrollment $_{1890}$.

[b] The growth term as discussed in the text is enrol$_{t-5}$ (eligible-age pop.$_{t-5}$ − enrol$_{t-5}$).

[c] The population variables are also constructed as difference terms at 5- and 10-year intervals.

[d] Immigration variable is the number of immigrants arriving each year, lagged 5 or 10 years.

lation are positive and significant. The number of immigrants has a negative effect for both lag periods between 1890 and 1924 in equations A and B, but the coefficient is not significant for the 10-year lag. In contrast, the number of immigrants has a significant positive effect in the period from 1925 to 1970 as shown in equations E and F. A similar pattern appears in the results for secondary-school enrollment. The growth term again is, as expected, positive in each equation for both time periods. The eligible age-group population is, however, negative in the earlier period (equations C and D); though its effects return to positive in the later period.[5] The pattern of effects of immigration on secondary enrollments is similar to its effects on primary enrollments. In the earlier period, the effects of immigration are negative (equations C and D), though the coefficient is not significant for the 10-year lag. In the later period, the effect of immigration is negative, but not significant for the 5-year lag; but this effect is positive and significant for the 10-year lag.[6]

The general conclusion from Table 4 is that immigration has had a negative effect on the rate of public primary- and secondary-school expansion between 1890 and 1924; but, after the enactment of the National Origins and Quota Acts, the effect of immigration has been positive. During the period 1890–1924, when there was widespread concern with the character of immigration, and nativist sentiment

---

[5] The negative effects of the eligible age-group population for secondary enrollment in the earlier period probably reflect the relatively low levels of secondary enrollments at the start of the period. The dominant demographic effect, then, is due not so much to increases in the eligible population but rather to the interaction of the eligible population and already enrolled individuals as embodied in the growth term.

[6] The Durbin-Watson statistics reported in these tables do not always reach significant levels, meaning that we cannot reject the hypothesis of first-order autoregressive serial correlation. The presence of such serial correlation may affect the significance of the coefficients, but the coefficients are still unbiased. We base our arguments in the text on the consistency of the signs of the coefficients for immigration on both public and private enrollments in the two time periods. When equations contain lagged endogenous variables as specified in Equation 1, the Durbin-Watson statistic is not always an appropriate test for first-order autoregressive serial correlation.

[e] Unemployment variable is lagged 5 or 10 years.

was greatest, the effect of immigration on the growth of public schooling was negative. We see that immigration has had a positive effect on the expansion of public schooling only after legislation had altered the character of immigration in favor of those from northern and western Europe.

Before we accept the conclusions from Table 4, however, we need to take account of economic conditions. Variations in immigration have always been related to the business cycle; and school enrollments have often responded to cycles of the economy, with more people staying longer in school during bad economic times. Therefore, in analyzing the effects of immigration on school expansion, we need to control for the potentially confounding effects of economic conditions. Table 5 shows the consequences of immigration on schooling when the unemployment rate, our measure of economic conditions, is added to the equations in Table 4. The data on unemployment are from Lebergott (1964) and the United States Department of Labor (1972). Table 5 shows that the effect of unemployment is generally positive and significant, as was expected. Where it is not positive (equations D, G, and H), its effect is not significant. More importantly, the inclusion of unemployment does not alter the effects of immigration.[7]

These findings show that the effects of immigration on aggregate rates of the growth of public-school enrollment have varied as a consequence of the character of the immigrants themselves. The finding that immigration had a negative effect on the growth of public schooling during the period when the immigrants were predominantly from eastern, central and southern Europe, and that the effect of immigration was positive during the period when the immigrants were predominantly from northern and western Europe, leads toward explanations based on the societal reactions of political and economic elites and of nativist groups to the different types of immigrants in the two periods. It may be argued, however, that the negative effect of immigration between 1890 and 1924 was due to the presumed fact that the schooling capabilities and motivations of these immigrants were lower than those from northern and western Europe. As a consequence, these children may have been less likely to go to school at every grade or, if in school, their lower capabilities resulted in higher rates of failure. Both of these mechanisms could produce a negative effect of immigration on the growth of enrollments during this earlier period. Certainly the public controversy at this time presumed that these new immigrants lacked motivation and the same level of natural abilities as the older immigrant groups from northern and western Europe (Higham, 1974; Kamin, 1974). But the data presented in Tables 1 and 2 argue strongly against such an explanation for the negative effect of immigration on enrollment. For these tables reveal that, in the period when we would expect these differences in schooling experience to be most marked, the rates of school attendance and of retardation, or of flunking, were basically the same for the children of immigrants and of native-born fathers.

---

[7] Change in GNP was also used as a measure of economic business cycles in parallel analyses. The results of these equations were similar to those using unemployment.

But we can go further in our analyses. If these schooling experiences of the children of immigrants and of native-born fathers were similar, and there is a negative effect of immigration on enrollment growth of public schooling during this period, then we should expect to find a positive effect of immigration on the growth of private-school enrollments from 1890 to 1924. We turn now to an analysis of private schooling.

The Growth of Private School Enrollments

The growth of private education has often been interpreted as a consequence of the desire of minority groups to maintain their separate identities when they feel public schooling is imposing dominant cultural values on them (Katz, 1968; Meyer, 1970; Meyer and Roth, 1970). Parochial education exemplifies the desire and commitment to maintain and reinforce religious identities and values that differed from the Protestant-dominated public schools (Tyack, 1970). It is equally plausible that the children of immigrant groups attended private schools as a result of the inability or unwillingness of public schools to incorporate them, rather than as an assertion of their independent status (Ravitch, 1978:58). As with the analysis of public schooling, our data do not allow us to determine the exact reasons for any relationship between immigration and the growth of private schooling, but we can find if such a relationship does exist.

The enrollment data for private schooling does not appear separately for primary and secondary levels throughout our time periods. Table 6, then, reports the effects of immigration within the two time periods for combined primary and secondary private schooling, including equations with and without the inclusion of unemployment. As in Tables 4 and 5, the effect of the growth term is always positive and significant in all equations except equation C. As before, the eligible age-group population has negative effects in the earlier period and positive effects in the later period.

The effects of immigration on the growth of private schooling support our expectations. As shown in Equations A through D, the effect of immigration during the period 1890 to 1924 is always positive and significant. Unemployment, though positive, is not significant and it does not affect the relationship between immigration and enrollments. The effect of immigration in the later period, however, is consistently negative, though significant only in equation E. Unemployment has a negative but not significant coefficient, and its inclusion does not alter the relationship between immigration and enrollments.[8]

The findings in Table 6 stand in marked contrast to those in Tables 4 and 5. Those two tables showed that the effect of immigration had been to lower the rate of growth from 1925 to 1970. The effects of immigration on private school enrollments have been just the opposite. In the period 1890 to 1924, immigration increased the

---

[8] The consistent nonsignificant effects of unemployment on private enrollments can be interpreted to mean that the general tendency of people to stay in school during bad economic times holds true for public schooling but not for private.

[e] Unemployment variable is lagged 5 or 10 years.

rate of growth of private schooling and decreased this rate from 1925 to 1970.[9]

Conclusion

The major conclusion from our empirical analyses is that the effect of immigration on the expansion of education has varied as a function of the character of the immigrants. From 1890 to 1924, during the period of the new immigration from eastern, central, and southern Europe, the effect of immigration was to decrease the rate of growth of public-school expansion and to increase the rate of growth of private-school expansion. After 1925, when the character of immigration shifted to favor the older immigrant groups from northern and western Europe, the effect of immigration was to increase the rate of growth of public-school expansion and to decrease the rate of growth of private-school expansion.

How do these findings contribute to the development of a theory of school expansion? Most importantly, they show that the growth of schooling responds to the character of social groups as this affects their interaction with other, more established, groups in society. The study by Meyer et al. (1979) showed that the early expansion of public primary schooling was a function of the cultural and organizational role of the nativist millenial-Protestant groups in the United States. Our findings complement and expand on this process by which educational expansion develops as a consequence of the social character of groups and their interaction with each other. The new immigrant groups which came to the United States between 1890 and 1924 were generally viewed as a cultural and political threat by many established groups. They were, in most respects, seen as carrying cultural and political traditions opposite to those of dominant elites and nativist groups and their presence generated a great deal of cultural and political conflict. Our findings, then, stand in a complementary relationship with those of Meyer et al. (1979). He showed that the presence of the nativist millenial-Protestant groups increased the aggregate rate of public school expansion. Our findings have shown that the influx of groups of opposite character decreased the aggregate rate of public-school expansion and increased the rate of private-school expansion. After the National Origins and Quota Acts of 1924 shifted the character of the immigrants, immigration increased the rate of growth of public schooling and decreased the rate of growth of private schooling.

---

[9] These results also clarify a finding in the analyses by Meyer et al. (1979). They found a negative effect of the proportion of the population that was Catholic and an insignificant negative effect of the proportion of the population that was immigrant on public primary enrollment. As they did not have enrollment for private schools, they could not readily interpret these effects and used them as control variables. Our tables show that the effect of immigration was different for public and private enrollments.

The argument of Meyer et al. (1979) emphasizes the cultural values and world view of the traditional, nativist groups as the cause for their constructing a widespread system of public schooling. They emphasize the role of Protestantism and independent entrepreneurship. The immigrants who came to the United States between 1890 and 1924 were predominately Catholic and working-class laborers. The evidence we have presented here, however, does not lead us to emphasize the cultural values and world views of these immigrants as an explanation for our findings. Rather, what seems to be important is that these groups were different and were perceived as oppositional to the established groups in the United States. The rates of schooling of the children of immigrants and of native-born fathers were similar; therefore, the consequences of immigration for variation in the aggregate rate of growth in public and private schools from 1890 to 1970 must be understood as the net result of the actions of a large number of groups, not just of the schooling behavior of the immigrants and their children.

Contemporary theories of schooling which emphasize the actions of a wide range of groups are often divided into functionalist, class-conflict, and status-conflict perspectives (Bowles and Gintis, 1976; Collins, 1971; Ravitch, 1978). Functionalist and class-conflict theories stress the role of public schools as agencies of imposition which properly socialize groups to the cultural and political system of the United States. Since the immigration from 1890 to 1924 was clearly seen as a cultural and political threat, such theories imply the expansion of public schooling during this period as cultural, economic, and political elites supported increased schooling as a mechanism of imposition. But our analyses are not consistent with such a process, for our findings have shown that, during the period of such immigration, immigration had a negative effect on the rate of public primary- and secondary-school expansion. When the character of the immigrants changed—that is, when their origins no longer represented a cultural and political threat—then immigration had a positive effect on the rate of growth of public schooling. A status-conflict process of schooling can better explain our findings. Under this perspective, schooling is seen as an asset for group mobility. A status-conflict view is consistent with our findings that the influx of immigration between 1890 and 1924 caused a decrease in the rate of growth of public schooling and an increase in the rate of growth of private schooling, as the threat to the dominant status group could cause a restriction in the growth of public schooling, causing immigrant status groups to concentrate in private schools.

However, our findings alone are not enough to substantiate these more general theories about growth rates in education. One reason is that these theories have not been specified enough to deduce the effects of different groups on educational expansion. A second reason is that it is not the findings about any one specific group's consequences for education that will differentiate such theories. Rather, in order to develop a general body of empirical findings that can be used in the development of a theory of educational expansion, we need to accumulate a series of such studies across groups which vary in their relationships to other groups in society.

THE MEEK SHALL NOT INHERIT THE EARTH: SELF-EVALUATION AND THE LEGITIMACY OF STRATIFICATION*

L. RICHARD DELLA FAVE
North Carolina State University

American Sociological Review 1980, Vol. 45 (December):955–971

Stratified social orders are maintained through a wide variety of mechanisms, one being broad-based legitimation of the notion of unequal distribution of primary resources. My attempt to develop a set of propositions provides at least a partial explanation of how such legitimation is generated and maintained. I argue that both conflict and functional theory point, at least implicitly, to the importance of the effect of unequal distribution of resources on the development of the self—constructing my argument through application of Mead's theory of the self to the case of stratification. This application is shown, in turn, to be compatible with several lines of theorizing in social psychology, including equity and status attribution theory. Once basic propositions are developed, I discuss ways in which major social institutions maintain legitimacy through their effect on the self and explore some possible sources of delegitimation.

One of the most persistent features of human societies has been the existence of some form of stratification. Theorists have tried to explain it: functionalists (Parsons, 1949; 1953; Davis and Moore, 1945; Davis, 1948; Baltzell, 1958; Keller, 1963) have stressed the unequal functional importance of occupational roles; elitist conflict theorists (Pareto, 1935; Mosca, 1939; Dahrendorf, 1959; Lenski, 1966) have emphasized the inherently unequal ability of people to pursue the struggle over scarce resources; and radical conflict theorists (Marx and Engels, 1959; Miliband, 1969; Habermas, 1973; Anderson, 1977; Harrington, 1976) have pointed to a succession of historically specific types of social systems whose very structures (principles of organization) insure continuing inequality.

Despite their considerable differences, each type of theorist (Strasser, 1976)[1] regards legitimation as an important mechanism through which stratification is perpetuated (Coser, 1956; Habermas, 1973). Legitimation refers to a belief on the part of a large majority of the populace that institutionalized inequality in the distribution of primary resources (Rawls, 1971)[2]—such as power, wealth, and prestige—is essentially right and reasonable (Feagin, 1972; Rainwater, 1974; Jasso and Rossi, 1977; Alves and Rossi, 1978). While the specific rationales used to justify inequality vary from one time and place to another (Bendix, 1956; Dumont, 1970; Wilson, 1973), the essence of legitimation is based in the existence of some set of such justifications which is widely believed—indeed, justifications sometimes so taken for granted as not even to

This is a much-revised version of a paper presented at the meeting of the Society for the Study of Social Problems, September, 1978, San Francisco.

I would like to thank Robert L. Moxley and two anonymous reviewers for *ASR* for their most helpful comments on an earlier draft of this paper.

[1] In his analysis of the work of classical theorists, Strasser (1976) argues they can be classified along at least two dimensions: (1) in terms of their basic model of society (order or conflict) and (2) according to their fundamental political orientation (radical or conservative). For a thorough exposition of this classification scheme see Strasser (1976:19–27). Basing his analysis of contemporary stratification theory upon the Strasser typology, Kerbo (1975) has shown that for this group of theorists the radical-order cell is empty. Considering the macrotheorists to be discussed in this paper, Marx falls into the radical-conflict cell, Mosca into the conservative-conflict cell, and Parsons the conservative-order cell.

[2] It should be noted that the focus of this paper is social stratification which is ultimately concerned with *distribution* of resources. In contrast, the emphasis of Marxist class analysis lies in the sphere of *production*. While the relationship between these two spheres is enormously complex and will not be discussed here, it is important to realize that the attainment of socialism (Marx, 1959) or, more specifically, worker control of the means of production (Blumberg, 1968) is far from synonymous with the elimination and/or delegitimation of stratification itself.

be questioned (Shibutani and Kwan, 1965; Dumont, 1970; Moore, 1978).

Given the importance of legitimation in these writers' works, it is surprising that none, with the exception of Habermas (1973)[3], has attempted to develop a systematic theory of legitimation, one that would specify its causes, explain its strength under various conditions, and describe the process through which it ultimately becomes part of the individual's thought. The propositions I will develop should be a component of this type of theory.

In developing a theory of legitimation it is important to understand that legitimation is only one of a number of means of maintaining stratification, namely through gaining at least the tacit consent of the populace, especially those who are relatively disadvantaged. In fact, legitimation is only one of several consent-generating mechanisms. Others include hopes for future upward mobility for self or children (Chinoy, 1955; Lane, 1962; Lopreato and Hazelrigg, 1972; Form, 1976); fear of jeopardizing one's absolute standard of living (Mankoff, 1970); a feeling of powerlessness (Wright, 1976); fear that the freedom and popular influence existing under representative democracy could be lost in a revolution aimed at bringing about greater equality (Anderson, 1977); and the inability to imagine any egalitarian alternative model of society (Dahl, 1967; Mann, 1970; Sennett and Cobb, 1972; Sallach, 1974; Moore, 1978).

A comprehensive theory of stratification would need to consider all those mechanisms as well as all-important nonconsensual factors such as coercion (Lenski, 1966; Anderson, 1977), the influence of moneyed interests over government (Mills, 1956; Domhoff, 1967; 1971; Prewitt and Stone, 1973), and the structural imperatives of institutions in class-ridden societies (Miliband, 1969; Parkin, 1971, Harrington, 1976). While the development of such a comprehensive theory is far beyond my intended scope here, this work can be seen as one aspect of some such larger project to which a growing number of social scientists are contributing.

Legitimation, we should be careful to note, can apply to any one of at least four system levels: (1) the particular status occupied by a given individual or group, (2) the particular regime in power, (3) a particular system of political economy, and (4) stratification itself (Della Fave, 1974). The propositions to be developed here will focus primarily upon the fourth—the most general—level. However, the multileveled nature of legitimation must be kept in mind in order to understand how it is possible to make sense out of the seemingly paradoxical coexistence of interest group conflict, even to the point of revolution, and the continued legitimation of some form of stratification.

My objective is to develop propositions concerning legitimation through the use of the concept of self-evaluation.[4] Throughout, legitimation is treated as a process in which the structure of the larger society becomes incorporated within the inner consciousness of the individual (Mead,

---

[3] Habermas (1973) has approached the problem of legitimation by asking specifically, within the context of advanced capitalism, under what conditions the legitimacy of the existing inequalities of wealth—so integral to the system—will be seriously challenged. His answer is that this cannot happen until the economic crises that result from the working out of the internal contradictions of the system become displaced into the administrative (political) sphere. When this occurs, the contradictions remain, but their socially undesirable effects can no longer be attributed to the "nature-like" invisible hand of the impersonal market. Rather, they are traceable to the concrete decisions of identifiable government officials. This opens these decisions to public scrutiny and has the distinct potential for raising demands that violate the terms of the unequal status quo, what Habermas (pp. 68–9) calls the asymmetrical "class compromise" of advanced capitalism.

But here Habermas begs what I take to be the central question—namely, In the context of public discussion of this issue, under what conditions could the privileged members of a society mount effective, convincing arguments for their more privileged access to resources? As we shall see, the self-evaluation hypothesis addresses this question by specifying that successful arguments can be mounted only if the participants bring differential self-evaluations with them to such discussions.

[4] The concept of self-evaluation is not identical with that of self-esteem. The latter is far more general and refers to an individual's overall feeling about him/herself (Wells and Marwell, 1976; Coopersmith, 1967; Rosenberg, 1965). The concept of self-evaluation is specified later, herein.

1964:141). I will show the compatibility of this approach with three widely differing orientations—in macrosociology, in the microsociology of social behaviorism, and with empirical evidence derived from both survey and observational research dealing with a wide range of specific topics.

Then, first, I review relevant aspects of the work of Marx, Mosca, and Parsons (representing three major approaches in macrosociology—namely, radical conflict theory, elite conflict theory and functionalism), respectively (Strasser, 1976), pointing out, despite their differences, important similarities in their treatment of legitimation. Second, I turn to social psychology (namely, Mead's theory of the self, recent work on status attribution and equity theory, and Bem's critique of cognitive dissonance theory); I define the concept of self-evaluation, explicate its role in the legitimation process and, at that point, specify propositions. Third, I discuss the role of social institutions in the legitimation process and, four, conclude by exploring possible sources of delegitimation.

Macrosociology

The work of Marx, Mosca, and Parsons that I review is macrosociological in that its major focus is understanding why whole societies are organized as they are and why they change in particular ways. This does not mean that there is no concern with the social psychological processes that affect structure and change in societies—far from it. In fact, if these works lacked a social psychological side, it would have been far more difficult to identify relationships between them and the more explicitly social psychological work which I will also discuss.

Marx. Given Marx's view of capitalist society as rent by an irreconcilable conflict of interest between proletariat and bourgeoisie (Marx and Engels, 1959), he was faced with the task of explaining why this objectively defined conflict was not translated directly into class warfare over the very existence of the capitalist system itself. The answer, of course, lay in the concept of class consciousness. Workers display class consciousness in its rudimentary form as a result of their concrete struggles with employers over wages and working conditions (Marx, 1963:170–5; Marx and Engels, 1959: 19–20; Marx, 1906:396–7). Marx was confident that, after prolonged struggle and with the help of the radical party, workers would realize that only by overthrowing the capitalist system itself could they put an end to their own exploitation. He also believed they would come to see the pivotal role assigned to the working class by history—that of the liberator, rescuing mankind from the exploitation of class society (Marx and Engels, 1959:19)—by which action it would usher in a new era of equality and human freedom (Marx, 1959).

Marx (1959) was convinced, however, that even a successful revolutionary proletariat would still be under the sway of a capitalist-oriented ideology that justified more than trivial inequalities in the distribution of primary resources. Only after a period during which the revolutionary proletariat had actually been running the society would the working class arrive at a level of consciousness that would support the idea of equality, with exceptions based solely on the basis of need. Therefore, it is understandable how, in the absence of fully developed class consciousness, bitter conflict could coexist with the legitimation of stratification (a point to which we will return, later). While Marx fails to explain how the ideology of the ruling class became incorporated in the consciousness of the workers in the first place, he gives us some potentially fruitful insights into the legitimation process, insights that can best be understood if we look at the way stratification is supposedly delegitimated.

In Marx's schema, three things precede the delegitimation of stratification. First, the workers embrace an ideology that casts them in the role of the deliverers of mankind from oppression. Second, they are actually victorious in revolution. And third, they have the experience of successfully running an entire society by themselves, without the aid of their "betters." All three things, especially when taken together, are powerful sources of confidence in one's ability to control one's world, to act competently. Conversely, the experiences faced by workers (in their subordinated positions within the normal workings of capitalism) work to undermine that confidence—to make them feel dependent, powerless, and of little value.

In our subsequent discussions of the work of Mosca and Parsons we shall see that similar implications can be drawn, despite the sharp disagreements between each of these writers and Marx and, indeed, despite their differences with each other.

Mosca. Unlike Marx, Mosca saw no Utopian vision of equality nor freedom from the domination of some type of elite. In fact, central to his approach is the notion, often credited to Pareto (Meisel, 1965), that the few, everywhere and always, shall rule the many (Mosca, 1939).

While Mosca readily acknowledged that the dominance of elites rested heavily upon the use and threat of force, he was acutely aware of the importance of legitimation. Regardless of which elite happened to be in power, it promulgated a political formula that emphasized the allegedly superior qualities of its members (Mosca, 1939:82–92), by portraying them as being especially intelligent, moral, energetic, and/or strong. Most importantly, that political formula always portrays the ruling elite as embodying the society's most cherished values in greater measure than do other classes. Here, he introduces a theme that later recurs in the writing of Schumpeter (1951) as well as of functionalists such as Parsons (1949; 1953) and Davis and Moore (1945)—that is, the notion that members of the elite claim superior competence in precisely those activities (functions) that are most crucial to the particular society's survival and prosperity, those things such as military virtue, ritual purity, commercial acumen, or impartial justice.

Despite the variability in types of society and the qualities claimed by elites, his political formula is everywhere and always based upon the premise that superior people deserve to rule and enjoy the perquisites thereof. The successful promulgation of such a political formula cannot help but enhance, among members of the ruling elite, their feelings of competence and of being important and valued and yet undermine, among the masses, those same feelings.

Parsons. Turning now to the leading writer in the functionalist tradition, Talcott Parsons, we note a very different model of society than is characteristic of either Marx or Mosca. For Parsons (1949; 1951; 1953), a society is an organic whole in which the parts are differentiated, yet coordinated, to work toward the best interests of the whole. However, the functions (occupational roles) performed by the various parts are not of equal importance. In fact, there is a hierarchy of functional importance, with those roles most central to the survival and prosperity of society occupying the highest ranks (Parsons, 1953:102–3; 1949:83–4).

For Parsons there is well-nigh total consensus among all segments of the population concerning the functional importance of the various occupational roles, a consensus embodied in the very moral order of society (Parsons, 1949:69–70). Successful performance of these highly ranked roles represents the highest level of conformity to society's norms. And since all societies must reward conformity and punish deviance, the incumbents of the most functionally important roles receive the greatest amount of rewards in the form of primary resources. For it to be otherwise would seem incongruous and wrong to any properly socialized member of a society.[5]

Thus, the legitimacy accorded the unequal distribution of primary resources is based upon the deeply internalized norms of the society and is not subject to instrumental considerations of individual self-interest (Parsons, 1951:551).[6] This implies

---

[5] Parsons is certainly sophisticated enough to allow for the effect of factors other than functional importance in influencing the distribution of primary resources, factors such as the selfish use of power in garnering privilege (Parsons, 1953:95–6). However, the Parsonian model treats the effects of power as a form of disturbance, just as Manchester economics treated monopoly in its model premised upon "perfect competition." Nowhere do the effects of power become an integral part of the model, as they are for all varieties of conflict theory.

[6] Parsons is worth quoting here:

> Institutionalization of cultural patterns means, as we have often emphasized, in the integrated sense internalization of the same patterns in the person-

that the belief in the superiority of those in the most functionally important positions is nearly universal and deeply internalized as well.

Parsons's notion of an internalized moral order, with its hierarchy of roles based upon the idea of differential functional importance for society, elevates the sense of worth of the functionally most important, while that of most others is humbled (Parsons, 1949:73).

We have seen a common thread running through the work of writers as diverse as Marx, Mosca, and Parsons. In each case there is an ideology that justifies a highly stratified system of resource allocation. But this ideology also allocates feelings of potency, competence, and, above all, importance and self-worth in a manner congruent with that of primary resources. In order to better understand the mechanisms through which distributions of primary resources are reflected in and reproduce congruent distributions of feelings of self-worth, we now examine works in social psychology.

Social Psychology

Any theory of legitimation must ultimately answer the question of how legitimations of stratification become part of the consciousness of the individuals who make up society. By focusing, primarily, on the concept of self, I will describe the various phases of a process through which this might occur, beginning with the work of Mead.

Mead. For Mead (1934) the self was a crucial concept in the study of human behavior because only by having a self does the human organism become a conscious, reflective person. The self is truly a creature of society as it can develop only from the reactions of others. We become conscious of ourselves when we realize that our gestures, including verbal ones, call out the same response in others as they do in ourselves. Once we have established this, we can then take the role of the "other" and anticipate others' reactions to us or to a third party. Thus, we become aware of ourselves through the reactions of others. (Mead, 1934:141–9).

Because of the prolonged and acute dependency of the human infant we develop strong emotional bonds with those who satisfy our vital needs. They become our first significant others, and their reactions take on great importance. As we mature, our needs become more diversified and, as our circle of contacts broadens, we acquire a growing number of significant others.

As the development of the self continues, we become aware of certain similarities between what others expect of us and how they react to us. People, in general, see us as bright or dull, attractive or ugly, strong or weak, capable or incapable. This amalgam of perceived generalized expectations and reactions constitutes the generalized other. It is through the generalized other that we come to discover who we are and what is expected of us. Though our views (of who and what we are) vary not only over time but also from one situation to another, for most of us there remains a degree of consistency and stability commonly associated with maturity and mental health.

In an illustration of how the generalized other develops, Mead (1964) uses the example of the way in which we come to develop conceptions of the value of different goods in the marketplace—through observing how others react to the goods and, specifically, by noting for how much they offer them for sale and, in contrast, how much they are prepared to pay for them. Keeping in mind the ability of the self to view itself as object, we can see that selves are able to develop a conception of their own social value in very much the same way as they are able to understand the value of goods (Blau, 1964). This important idea will be developed further when we review some of the work in equity theory.

Recent work in social psychology, rele-

---

ality. Psychologically an internalized pattern is no longer an object of the situation. It is not possible to treat it as an instrumental means or condition. There is a specific model of cathectic integration of the actor's need dispositions with an internalized pattern. This fact has a fundamental methodological significance. It means that the orientation of "instrumental rationality" *cannot* be the attitude defining the actor's orientation to internalized patterns. (Italics in the original.)

vant to the problem at hand, has stemmed from two related lines of theoretical development—namely, equity theory and status attribution theory. Both have benefitted from extensive laboratory experimentation. Once they have been described, they will be linked to Mead's theory of the self through the work of Bem (1967).

Equity theory. Equity theory is based upon the notion of a balance—that is, individuals have a built-in tendency toward cognitive consistency (Heider, 1958; Festinger, 1957). Its main principle is that human beings carry around in their heads a notion that rewards should be proportional to investments, an idea Homans (1974; 1961) calls distributive justice. When the principle of distributive justice is violated, people become angry—morally outraged, one might even say. The individual who contributes more to the activities of a collectivity ought to receive a greater share of the rewards than one who contributes less.[7] Contributions can be in the form of expenditure of energy, lending of expertise, donation of money, acceptance of responsibility, etc. Evidence supportive of this approach for small groups is abundant (Leventhal, 1975; Homans, 1974; Ofshe and Ofshe, 1970).[8]

The relevance of equity theory for a theory of legitimation of inequality in larger societies has been pointed out by Lerner (1975) and Walster and Walster (1975). Those in power are assumed to be contributing more and, therefore, are seen as deserving of greater rewards. If ego is not among the major contributors to the group, even he/she comes to feel deserving of lesser rewards. Thus, inequality is made to seem legitimate. However, the unanswered question is, *Why* do people tend to perceive those in power as contributing more? For an answer we must turn to status attribution theory. Before doing this, however, it is important to keep in mind several relevant differences between small groups and whole societies—especially large, highly differentiated ones. In societies, inequality of resources is enormous, as compared with small groups. In most small groups (certainly those studied in the laboratory), coercion is not available to enforce inequality, as it is in societies. Also, the life of small groups is very short; in fact, they lack a history. Thus, inequality cannot become institutionalized over generations. Finally, small groups are, by definition, collectivities in which the members interact face to face. There is none of the remoteness as exists between leaders and populace in large societies. Among other things, this means that it is much more difficult to manufacture an impressive image of oneself, thereby to inflate one's importance, in a small group than in a large society.

Status attribution theory. The development of status attribution theory, like that of equity theory, is based upon the assumption of a strain toward cognitive consistency within the individual. The central problem lies in how an individual assesses the status of another when only one (or a few) status-relevant clues are known (Berger et al., 1972; Webster and Driskell, 1978). Normally, the individual generalizes from what is known and assumes that a person's unknown status-relevant characteristics are consistent with the known ones.

Since status attribution theory describes the process through which the overall picture of an individual's status is pieced together from fragmentary clues, we can see, once this picture is completed, how it is used to assess, retrospectively, the individual's "contributions."

The need to assess an individual's "contributions" in this manner is strongest when direct, face-to-face contact is at a minimum, which is the case with leaders in large, highly differentiated societies. Equity theory then describes how this, in turn, becomes the basis for an estimate of the level of reward deserved (Cook, 1975). Thus, equity theory and status attribution theory are complementary. What is crucial is that the entire process through which the appropriate level of reward is determined is *circular,* in that the very fact of being wealthy or powerful influences our assessment of "contributions" and, on the basis of such assessment, we judge that person worthy of such a high reward.

---

[7] This same idea is implicit in the functionalists' use of the concept of differential functional importance and even in Schumpeter's (1951) and Mosca's (1939) use of the notion of elites contributing disproportionately to a society's survival and prosperity.

[8] For example, laboratory subjects who are led to believe that individual A has contributed most to the group's success, individuals B and C have contributed moderately, and individual D very little tend to say that rewards should be divided in such a way so as to favor A most, B and C somewhere in between, and D least (Leventhal et al., 1972).

In large societies the degree of inequality of resources is most often very great (Lenski, 1966), making it likely that the disadvantaged will be awed by the size of the gap and attribute very large differences to "contributions."

Bem. As impressive and promising as status attribution theory and equity theory appear to be in developing propositions about legitimation, their primary assumption—that there exists a strain toward cognitive consistency within the individual psyche—has been challenged by Bem (1967). He argues that a whole range of heretofore inexplicable findings in laboratory research dealing with balance theory can be readily explained, were that assumption altered.

Bem (1967) suggests that we do not postulate any hypothetical strain toward cognitive consistency but, rather, we assume that an individual derives judgements as to what an "objective outside observer" would view as reasonable. This shift in assumptions solves an important problem. Social psychologists have long been plagued by the accusation that their findings reflect culture-bound thought patterns rather than universal human tendencies (Sampson, 1975). If the definition of what is reasonable (consistent) emanates not from the innate structure of mind but from an image of an external observer, it follows that the observer can vary in his/her judgements, depending upon the culture with which a researcher is dealing and upon the nature of the subject's individual experience.

But what external, objective observer is available and also, at the same time, likely to have his/her judgements internalized? Mead's generalized other has precisely these characteristics. As in his example of buying and selling goods, the way we develop an idea of what is a "reasonable" price or value of goods is what we see others regularly charging and/or paying for them. We have just seen that this is precisely the way in which Mead sees the generalized other developing.

This observation enables us to link equity and status attribution theory with Mead's theory of the self, for it is from the generalized other that individuals form an evaluation of self and, thus, of the worth of their "contributions." It is upon these evaluations, in turn, that judgements of equity are made in accordance with the principle of distributive justice.

So far we have achieved two major objectives. The first was to locate a common thread running through the macrosociology of writers as diverse as Marx, Mosca, and Parsons, with respect to their treatment of legitimation. This common thread is a relationship between legitimation and self-worth or, as we shall refer to it hereafter, self-evaluation. The second objective was to show that recent work in social psychology (specifically, equity theory and status attribution theory) is complementary, and that this work can be linked to Mead's theory of the self. Taken together, the social psychological works describe several aspects of the legitimation process. What remains now is to tie this in with macrosociology, in order to generate propositions about legitimation.

Before moving to the propositions themselves, the concept of self-evaluation must be explicated. The individual develops conceptions of self with respect to any number of possible characteristics. However, here we are concerned with those characteristics relevant to the individual's relationship with the institutions of the larger society. from which come rewards in the form of primary resources, specifically those characteristics enabling the individual to dominate or gain favor within these institutions.

The basic dependency of human beings makes impressive any ability to dominate the environment, either physically or socially. In the face-to-face context, leaders—those who are treated as most socially valuable and who are granted disproportionate rewards—are those who demonstrate their personal competence or, at least, those who do so before others can demonstrate theirs (Webster and Sobieszek, 1974). However, in large societies, the "demonstration" of the ability to dominate is mediated through a number of factors mentioned earlier in discussing equity theory. Dominance of the external world is most effective when it permits the formation of a *publicly defensible* positive evaluation of self—that is, an evaluation that is defensible before the widest possible audience. The extent of the audience is important as the apparent objectivity of societal reactions contributes so heavily to their power to convince. As objectivity is defined as intersubjective agreement, the wider the audience, then the more certain one can be of the objectivity of the assessment.[9] Thus, self-evaluation, as defined here, is the individual's perception of the social value that others attribute to him/her. Those who perceive that they are viewed as important by the widest audience, and particularly by others who are also viewed as important, have the highest self-evaluation. We are finally at the point where the diverse material presented so far can be pulled together and the propositions derived.

The Legitimation Process

The primary question to which this paper is addressed is, How do ideologies that justify structured inequality in the distribution of primary resources become part of the social consciousness of individuals? The main proposition of the theory states: *The level of primary resources that an individual sees as just for him/herself, relative to others, is directly proportional to his/her level of self-evaluation.* The individual's level of self-evaluation is developed through a process of comparison (Rosenberg and Pearlin, 1978). Thus, individuals with relatively high self-evaluations will see themselves as deserving of high levels of resources relative to others, whereas those with relatively low self-evaluations will see themselves as deserving of relatively little in comparison with others.

A corollary of this proposition allows us to deal with a related question—namely, Under what circumstances will the stratification system of any society enjoy relatively high or low levels of legitimacy? It states: *The strength of legitimacy of stratification in any society is directly proportional to the degree of congruence between the distribution of primary resources and the distribution of self-evaluations.* What follows is a discussion of the ways in which these propositions are derived.

Those possessing greater wealth and power in a society will tend to be perceived as having more of a whole range of other positive characteristics than those less fortunate or powerful. Through the status attribution process, those possessing greater amounts of primary resources come to be seen as actually being superior. At this point, the principle of equity takes over, and people believe that those who appear to be superior deserve to be more richly rewarded. This generalization, derived from previously reviewed laboratory studies, finds support in survey research as well (Fox et al., 1977; Lopreato and Hazelrigg, 1972).[10]

---

[9] Thus, for example, while the positive feedback of family and friends is affectively gratifying and is an important source of self-esteem, it would seem to lack the objective power of larger-scale reactions. Measures of self-esteem or self-concept used in sociological research and designed to test for a relationship between these variables and position in the stratification system (Rosenberg and Pearlin, 1978; Jacques and Chason, 1977) have used very general measures of self-concept (see footnote 4). Thus, their finding of a positive correlation leads me to believe that if a measure more specific to self-evaluation in terms of mastery of, and confidence in, abilities related to success in instrumental activity in social institutions were used the correlation would have been all the stronger.

[10] For example, both Fox et al. (1977) and Lopreato and Hazelrigg (1972) found that legitimacy and acquiescence to authority were *inversely* related to the authority level occupied by the subject. Thus, those closest to the top were *least* acquiescent. This is contrary to a simple conflict-oriented expectation that those who, themselves, had least authority would be least acquiescent. But these findings are compatible with the self-evaluation hypothesis as we would expect those occupying positions of relatively higher authority to have higher self-evaluations. Therefore, we would also expect them to be less

Of course, the attribution of superior characteristics to those with greater wealth and power implies that those lower in the stratification system will attribute to themselves relatively inferior characteristics, through comparison (Rosenberg and Pearlin, 1978; Jacques and Chason, 1977). Thus, if they are, in relevant ways, inferior, then they deserve to have lesser wealth and power. This is consistent with research on relative deprivation (Rushing, 1972; Runciman, 1966) in which members of different strata tend to compare themselves with others of their own stratum, rather than with those noticeably either richer or poorer than themselves. The latter type of comparison is meaningless precisely because those persons substantially higher or lower than oneself are obviously deserving of correspondingly greater or lesser rewards. The differences are simply taken for granted. It is the relatively small differences in rewards between oneself and those similar to self that excite feelings of deprivation.

Because of the circular nature of the process just described, a given distribution of primary resources tends to reproduce itself in a congruent distribution of self-evaluations which, in turn, reinforces the very status quo that generated it in the first place. While this describes the basic logic behind the main proposition, a closer study (of the mechanisms through which the process may be operating) is warranted.

Discussion of the status attribution process revealed that when ego meets alter and knows only one or two of alter's status-relevant characteristics, ego attributes other characteristics to alter—which, in the eyes of an imagined generalized other, are consistent with the ones ego knows. However, the work of Goffman (1959) strongly suggests that alter often behaves in ways that help the attribution process along. Highly placed individuals, by virtue of their greater wealth and power, are able to control or stage their encounters with subordinates in such ways as to impress them. For example, they may display their wealth in their personal appearance and in the very settings in which encounters take place. Also, the subordinate goes to his/her superior, not the reverse. Another staging device is the appearance of being calm and in control (Hall and Hewitt, 1970). The power to dictate explicitly, or better yet implicitly, where a meeting will be held is a convincing display of power. The subordinate's constant awareness of his/her asymmetrical dependence upon the superior serves this function (Emerson, 1962), as well as the superior's ability to make the subordinate wait (Schwartz, 1974).

Finally, the ability of superiors to stage their encounters allows them to shield their shortcomings from the view of subordinates. A good illustration of this is the fact that the deviance of the poor is more often performed in public places and is, thus, more visible than that of the rich (Johnson et al., 1977; Chambliss, 1973).

The process that generates differential self-evaluation does not operate in a vacuum but, rather, within the framework of social institutions—especially institutions such as the school and the workplace which are instrumental in determining one's place in the distribution of primary resources (Bowles and Gintis, 1976). Differential placement within these institutions, resulting from both competitive achievement and ascription, generates, within individuals, conceptions of where they stand in the larger society.[11]

---

likely to accept the legitimacy of the authority above them than would those with lower self-evaluations.

[11] In the case of schooling, Clark (1965) and Rosenthal and Jacobson (1968) have argued cogently that children who are treated as unworthy and incapable of learning are likely to internalize these judgements and fulfill the negative prophecies about themselves. Brookover and his associates (Brookover and Erickson, 1975; Brookover et al., 1964) have shown the strong impact that the school's evaluation of students' academic performance has upon their conceptions of their own ability, even when I.Q. is held constant. And Rosenbaum (1975) has shown how even the placement, itself, of high school students in "tracks," helps to determine I.Q.

In terms of the workplace, Kohn (1969) has shown how demands for conformity at work shape the individual's conception of his and his children's place in the realm of authority and obedience. We have seen how, from gradations of pay and the symbolic perquisites of office (Whyte, 1957) to the respect (or lack of it) with which one is treated on the job (Sennett and Cobb, 1972), the individual is confronted with seemingly objective and powerful messages about him/herself. At the negative extreme, the ef-

We have seen how the possession of greater primary resources allows dominants to control (through social institutions) the character of relationships between themselves and subordinates. One result of the establishment of these controlled relationships is the development of a generalized conception within the culture of the superiority of those who are highly rewarded and, by implication, the inferiority of others. This generalized conception develops out of communication among status-homogeneous groups. This is important because dominants maintain a certain degree of social distance between themselves and subordinates, which means that encounters with any one subordinate may not be frequent. Sharing of experience through communication creates a generalized set of expectations surrounding such relationships, expectations that become internalized through their embodiment in the generalized other. Through this process, the individual develops an evaluation of self with respect to the larger society. When the self-evaluations are congruent with actual command over primary resources, legitimacy emerges—as our corollary states. Through the resulting ideology, the circular logic of the legitimation process reinforces the stratified status quo.

If this description of the legitimation process is accurate, then the inverse of the corollary should also be true—namely: *The more incongruent the distribution of resources and self-evaluations, the more likely is the delegitimation of stratification.* This last point cannot be emphasized too strongly. Simply because I have referred to the legitimation process as self-reinforcing does not mean that "might becomes right," automatically. It is only when the distributions of resources and self-evaluations are congruent that it appears to do so. However, it is important to realize that, under most circumstances, the condition of congruence holds very well. This is precisely what accounts for the seemingly automatic character of the legitimation process, which may well have (mis)led functionalists into seeing it as universal. However, I maintain that incongruence between the two distributions can be produced by a number of forces—both internal and external to a society.

In order to round out the exposition of self-evaluation theory we must return to a question raised earlier—namely, How can the legitimation of stratification coexist with extensive intergroup conflict, and even revolution? The first step toward resolving this apparent paradox is to refer to our discussion of the four (system) levels at which legitimation can exist: (1) the position of the individual or group within a stratified order, (2) the particular regime in power, (3) the system of political economy, and (4) stratification itself. The specification of these levels shows how it is logically possible for legitimation to exist on some levels while conflict might prevail on others. This suggests that theories based upon conflict and those based upon consensus need not be incompatible but, rather, may simply be applicable to different system levels, but it fails to explain why this occurs or at which levels legitimation or conflict could be expected to be the dominant pattern.

Note also that these four levels fall along a continuum ranging from the more concrete to the more abstract. There appears to be a pattern in which conflict prevails at the more concrete levels while legitimation remains on the more abstract levels. For example, Marx and Engels (1959) note the tendency of workers to focus their discontent over poverty, harsh working conditions, and economic insecurity upon what appears to them to be its most immediate source—their employers or the machines being introduced into the factories. Similarly, Lenin (1963) observed that, left to their own devices, workers would not go beyond "trade union consciousness."

More contemporary writers have echoed that theme. Mills (1956) argued that people tend to be absorbed almost totally within their own limited milieux and are seldom able to connect private troubles with public issues. Both Mann (1970) and Parkin (1971) have pointed to the importance of a radical ideology which enables people to see the linkage between

---

fects of being locked into a cycle of menial jobs (Liebow, 1967) or, worse, prolonged unemployment (Bakke, 1940), can be nothing short of devastating.

everyday discontents and their systemic causes. Giddens (1973) has gone furthest in specifying a rather exacting set of conditions that must be fulfilled if workers are to proceed beyond a mere struggle with employers over economic issues (conflict consciousness) to the point where the legitimacy of the capitalist system is called into question (revolutionary consciousness).

Additional support for the existence of this pattern can be cited. Liebow's (1967) observations of unemployed blacks, and Sennett and Cobb's (1972) interviews with blue-collar workers both revealed, on the one hand, considerable resentment over material conditions and the low regard in which society holds them and, on the other hand, a virtually total failure to bring the legitimacy of the system itself into question. Needless to say, in no instance was the legitimacy of stratification itself ever challenged. Similar observations are reported by students of the Hindu caste system (Dumont, 1970; Mandelbaum, 1968).[12]

On the basis of this evidence I might frame a second proposition: *The probability that legitimation will prevail is directly related to the system level of abstraction.* That is, the higher the level of abstraction, the more likely a self-reinforcing legitimation process is to be found. At the very highest level—which is the focus of this paper—it has been nearly universal while, at the lowest level, conflict manifest in various forms has been the rule. Examples of those forces that might promote delegitimation and, therefore, signal the applicability of conflict theory at the highest level are now discussed.

Summary and Discussion

In recent years, conflict theory has gained an important place in American sociology and has shed much light upon the way in which stratification systems are initially established. However, conflict theories are much less effective in explaining exactly how stratification becomes legitimated; they offer concepts such as false consciousness and political formula but fail to describe the mechanisms through which the legitimation process operates (Marx and Engels, 1947).

Functional theory, which assumes the existence and internalization of a common value system among all strata of the population, has always purported to explain how an ongoing stratification system is legitimated. However, it has done so in a manner that is incompatible with the considerable achievements of conflict theory; for it has all but ignored the role of power and conflict. Moreover, it has assumed the inevitability of stratification and its legitimation and, therefore, precludes a priori the search for the conditions under which it might not exist (Gouldner, 1970).

The self-evaluation hypothesis is fully compatible with a conflict orientation in both its radical and elitist varieties. Like most conflict theories it, too, goes beyond the conception of stratified societies being held together exclusively by either force or the threat of force. However, it does more than simply allude to the role of ideology or ruling ideas in legitimating stratification. It describes legitimation as the outgrowth of social psychological processes operating within the confines of asymmetrical relationships embedded in major social institutions. A major strength of the self-evaluation hypothesis is that it can account for the coexistence of both legitimated inequality and a self-interested struggle over resources on the part of all strata in society.[13]

---

[12] In the Indian case, discontent most often took the form of a desire for upward mobility of the entire jati, not the lone individual or nuclear family. But acceptance of the caste system was in all cases implicit.

[13] This presents a grave problem for a theory such as Lenski's, for example. Lenski (1966:25–32) takes as one of his basic assumptions the idea that *man is essentially selfish*. However, given this assumption, he has difficulty explaining why most people who have been on the short end of grossly unequal social arrangements have, even so, accepted them. To solve this problem, Lenski advances the further assumption that man is a creature of habit and, for that reason, routinely accepts such unequal arrangements.

But he cannot have it both ways! *Which* individuals will behave selfishly or be slaves to habit at what points in time and under what conditions? In terms of

Unlike functionalism, the self-evaluation hypothesis does not *assume* the existence of a common value system. It achieves compatibility with functionalism by describing a process through which an ideology which justifies stratification comes to be commonly accepted by all strata—even the poor, in apparent contradiction to their self-interest. It also proposes an explanation of why this process *appears* to be inevitable and universal. In this sense, it takes seriously functionalism's insistence upon the existence of a common, objective standard of evaluation that is widely internalized (Kraus et al., 1978), in a way that conflict theory never really has been.

The self-evaluation hypothesis has also shown its ability to interpret a range of empirical data from both surveys and observational studies. While direct tests of the propositions stated here have not yet been made, their compatibility with so many theoretical orientations and existing findings suggests that they merit serious consideration.

One of their most promising features is their ability to explain why so many disadvantaged persons hold beliefs concerning stratification seemingly contrary to their "objective self-interest" while the views of the privileged seem to be more consistent with their interests (Cheal, 1979; Feagin, 1972).[14] Among the privileged, in terms of the propositions, self-evaluations coincide with self-interest. They tend to have high self-evaluations based upon their advantaged circumstances and success in dealing with the world. Such evaluations lead to their feelings that they *deserve* what they have. Among the disadvantaged, however, their self-evaluations are inconsistent with their interests. Having relatively low self-evaluations, they don't see themselves as *deserving* equality with those "better" than themselves (at least in terms of power and wealth). If the propositions are correct, the exceptions who are egalitarians ought to be precisely those individuals, among the disadvantaged, who have especially high self-evaluations (Feagin, 1972).

However, no claim is made that this is an exhaustive theory of mass support for inequality. As I pointed out from the start, factors other than self-evaluation are very likely to generate such support—even among people whose self-interest would seem to dictate support for equality. Only by taking all of these factors together can the maintenance of stratification in modern society be explained.

No discussion of legitimation would be complete without a consideration of the conditions under which stratification might be delegitimized.

Delegitimizing Stratification

It is important that we recognize the "dual nature" of the legitimation process.

---

legitimation, these two orientations are diametrically opposed.

The self-evaluation hypothesis resolves that problem by differentiating system levels at which legitimation (habit) and conflict (selfishness) orientation prevails. The theory states that: While low self-evaluation fosters acceptance of a lowly position (as incongruence between self-evaluation and self-interest leads to ambivalence) it also recognizes that people at all levels will react negatively to what they regard as threats to their self-interest.

[14] Cheal (1979) argues that Conservatives in Britain have a highly consistent ideology that favors the perpetuation of existing class relationships. Labourites, on the contrary, have a confused ideology that is in some ways opposed to existing arrangements but, also, in numerous ways supportive of them. *This,* Cheal (1979) argues, is a major reason why the disadvantaged have not been able to organize to alter, fundamentally, the existing system of class privilege (see also Schulman et al., 1976).

In terms of our hypothesis, the confusion in the ideology of the disadvantaged stems from the lack of coincidence between self-interest and self-evaluation among this segment of society.

It is Cheal's (1979) contention that the existence of a radical party is capable of reducing the confusion in the ideology of the disadvantaged. For him, as well as for others (Parkin, 1971; Mann, 1970), the radical party is able to provide cognitive structures that point out the linkages between the conditions of their lives and the principles upon which the present system is organized, linkages that provide people with a version of an alternative social order. While not taking issue with this approach, I suggest that the party provides another equally vital function—namely, to raise the self-evaluations of the disadvantaged. Marxist parties, for example, do this by promulgating the idea that the working class has a pivotal role in history, no less than that of ending oppression itself. The party can also make itself a powerful source of positive self-evaluation by actually being successful in wringing concessions from the system.

On the one hand, as I have argued repeatedly, it is self-reinforcing. Any given distribution of primary resources has a strong tendency to produce a congruent distribution of self-evaluations through a set of very basic social psychological mechanisms. On the other hand, the process is not totally automatic. In a thousand little ways it must be maintained and reconstructed, anew, on a daily basis (Berger and Luckmann, 1966).

Maintenance of legitimation involves the staging process in which social distance must be maintained and people must be duly impressed. The generalized conception (within the culture of elite superiority) must be reinforced directly through the mass media; control of subordinates and manipulation of their sense of self-worth must be continued within major social institutions through the exercise of hierarchical authority; channels of upward mobility must be kept open to the most talented members of subordinate strata.

While isolated cases of failure to maintain any of these facets of the system are unlikely to be fatal, a large-scale pattern of failure could initiate a chain of events which, under appropriate conditions, might undermine the legitimation of stratification. Since, theoretically, the delegitimation of stratification is possible, under what conditions might it occur?

I have hypothesized that delegitimation comes about when incongruence develops between the distribution of primary resources and that of self-evaluations. Though there are many logically possible ways in which incongruence may develop, I will focus on only a few here. In the first instance, the evaluation of the elite is lowered in the eyes of the populace so that, for most, the gap between the evaluation of self and that of the highly rewarded is narrowed, without any concomitant narrowing of the gap in terms of resources. In this case it is also possible that highly rewarded persons, reacting to the incongruity, would lower their evaluations of themselves to a point at which they feel overrewarded and experience a "loss of nerve."

One way in which such an eventuality might come about is through a failure of the dominant stratum to continue to keep the economy running smoothly and/or to fail to maintain order (Mankoff, 1970; Gurr, 1970). In either case, an objective failure on the part of the regime would weaken the ability of leaders to present themselves as possessing superior competence.[15]

In the second instance, the actual extent of inequality of resources is suddenly shown to be much greater than was previously suspected. This could occur either through changing ecological patterns that force rich and poor to observe at close hand the way each other lives, or through media exposure.

While both of these instances result in incongruity, it is of a negative sort—brought on by disenchantment with superiors. Elites, as leadership groups, are seen as those who are needed to perform society's most vital functions and make its most important decisions. Negative reactions to elites, with no concomitant rise in the self-evaluations of the masses, are very likely to simply initiate a search for more worthy elites to take the place of the fallen ones. Stratification still remains.

This leads to the third instance. Here, incongruity is generated through a rise in the self-evaluations of the disadvantaged. As a result, the privileged no longer seem especially worthy by comparison. In this instance, the disadvantaged come to feel more confident about their ability to shape their own destiny in the larger world.[16]

---

[15] None of this is meant to imply that a breakdown of the authority of elites in any society necessarily leads to radical change in that society's structure, let alone to an egalitarian society. Clearly it does not! On the contrary, it should be very clear at this point in our discussion that an egalitarian society might emerge only under a very carefully specified set of conditions that are extremely difficult to satisfy.

Sabotage and terrorism are tactics designed to precipitate such a breakdown. So, too, is the general strike. But for most people, disgruntled as they might be, the prospect of such drastic, dangerous, and illegal action inhibits them (Wilson, 1973). This, of course, makes reasonably easy the isolation of extremist groups who use such tactics, unless the state itself is already very weak or unless mass opposition is extremely strong, widespread, and well organized (Balbus, 1973). Another possibility would be a sustained exposure of elite misdeeds and/or incompetence through vigorous investigative reporting.

[16] There are a number of possibilities. First, there is the spread of literacy and, then, of higher educa-

While my main concern has been class stratification, one might argue that a hypothesis as general as the one advanced here should be applicable to other forms of stratification, as well, such as racial or sexual. But these forms of stratification involve only the first system level of abstraction, the placement of particular categories of individuals within a given stratification system. They can, theoretically, be eliminated while the society remains class-stratified—that is, members of previously subordinate racial groups, or women, can have an equal chance of high or low placement, with inequality itself being firmly entrenched. This would be the prototypical meritocracy. Thus, we should expect a much higher probability of conflict and a much lower level of consensus over the legitimacy of these forms of stratification than over the very idea of stratification itself. Yet it might be fruitful to explore the possible relevance of the relationship between the distribution of resources among racial groups and their self-evaluations, particularly the effect of suddenly elevated levels of minority self-evaluations or the high self-evaluations of members of minority elites whose opportunities for advancement are blocked. But these issues are much too extensive to be treated here and must be relegated to another study.

The self-evaluation hypothesis overcomes the static bias that afflicts not only functionalism but also the elitist types of conflict theory that treat stratification and its legitimation as being inevitable. By taking a dialectical approach (Ball, 1979) it opens up the very question of the conditions under which these two persistent characteristics of social life are likely to be present in varying degrees or, even, entirely absent.

tion. When the spread of such education exceeds the availability of jobs characterized by suitable status, autonomy, intrinsic challenge, and money, incongruence can develop. Perhaps the increasingly pronounced stratification of higher education (Bowles and Gintis, 1976; Karabel, 1972), competency testing, and other efforts having the effect of reducing the extent of "status inflation" through education (Milner, 1972) may have the effect of heading off this potential threat. In fact, there is evidence that the college enrollment rates, at least for whites, are declining (U.S. Bureau of the Census, 1979; 1971), thereby reducing this pressure. Nevertheless, if the self-evaluation hypothesis is valid, one cannot neglect the role of the spread of literacy as a force favoring greater equality (Lenski, 1966). Neither can one neglect the importance of the extension of citizenship rights to the masses (Anderson, 1977; Marshall, 1964). By placing additional political resources, however formalistic, in the hands of the people, one is likely to raise their levels of self-evaluation. Given the importance of social institutions in developing people's self-evaluations, it would seem that any move toward the democratization of these institutions—be they schools, workplaces, or families—would tend to create greater equality of self-evaluations, as people would actually experience greater control over, and responsibility for, their own lives.

Still another possibility of raising the self-evaluations of the masses is through getting people involved in some sort of organized activity in which success can be demonstrably achieved (Alinsky, 1971; Freire, 1970). As students of revolution have long recognized, it is those groups actually making gains who are emboldened to press further demands (Brinton, 1938). My introductory review, herein, of Marx's work showed that he was keenly aware of the central role of struggle in raising consciousness. More recently, Anderson (1977) has argued that massive support for socialism in Western democracies can come about only through the actual successes of working-class-dominated parties within those democratic structures. In the absence of successful involvement, one is faced with the formidable task of convincing people of their own worth without having compelling, objective back-up evidence. This, indeed, is the key problem.

RESEARCH NOTES

SUBURBAN STATUS INSTABILITY*

HARVEY M. CHOLDIN, CLAUDINE HANSON, AND ROBERT BOHRER
University of Illinois, Urbana–Champaign

American Sociological Review 1980, Vol. 45 (December):972–983

Contrary to conventional urban theory, recent studies have found "suburban persistence" in social status, over time. This concept is challenged here, in an examination of change in relative status of places. Three simple indexes of relative status are introduced and analyzed over time in a cohort analysis. It is shown that status typically rises for about two decades after a suburb is built and then it declines. Thus, like city areas, suburbs follow the neighborhood life cycle. Earlier studies which found suburban persistence are criticized for using panel designs in combination with correlational statistics, which were unable to detect the kind of change occurring in metropolitan areas.

Two recent studies of the social status of suburban communities conclude that such places tend to be stable over time, that "suburban persistence" occurs in United States metropolitan areas. In the first study, Farley (1964:38) observed, "Particular suburbs retain their peculiar socioeconomic characteristics for long periods of time and even rapid population growth does not produce substantial changes in a suburb's socio-economic characteristics." Likewise, Guest (1978:262) concluded: "Amid the massive suburban growth of post-World War II America, most suburbs retained a very high stability of relative ranking in social status." These findings are inconsistent with previous theories of urban development, which state that residential areas tend to change and decline over time.[1]

A historical perspective on urban development, however, suggests that suburbs will change over time if they behave like previous types of high status residential areas. Certainly high-status places have changed in earlier periods. For example, a series of Chicago maps showing the locations of elite residential areas (Hoyt, 1939:83) showed that the upper class had shifted its location every 30 years. Indeed, once-elite areas later became slums. Why should sociologists presume that the current period is frozen and that local status in the metropolis is stable, knowing that status patterns have shifted and changed throughout United States urban history?

Unlike those who now see stability, previous urban theorists—viewing city neighborhoods rather than suburbs—emphasized evolution and change of residential areas. Perhaps the earliest sociological theory to this effect was "residential succession" (Burgess, 1925; 1928), which explained how a sequence of groups occupied a given city location. As a group rose in status it was likely to abandon its environment which would then be taken by new occupants of slightly lower status. "Filtering," the process by which residences are passed down to less prosperous occupants, is another concept of residential change (Lowry, 1960). A third expression of the general concept of

Bohrer's participation in this project was supported by the National Science Foundation under grant MCS79-02581. Alan Booth, Joan Huber, James Klugel, and Daphne Spain helpfully criticized an earlier draft of this report.

[1] Other sociologists (Logan, 1976; 1978; Stahura, 1979a; 1979b; Collver and Semyonov, 1979; Marshall and Stahura, forthcoming) have recently studied suburban status with varying interpretations of change.

subcommunity change is the "neighborhood life cycle" (Hoover and Vernon, 1962:183–98), which posits a series of stages in which residential areas start as new housing developments, mature, and decline into old, run-down, undesirable environments. All three of these concepts—succession, filtering, and neighborhood life cycle—consistently portray downward change, not stability, among residential areas.

Recent suburban trends imply that local socioeconomic status may not be stable. The oldest suburbs, built in the first decades of the twentieth century, now have old housing, noncompetitive business districts, and concomitant local problems. The suburban zone is absorbing many central city functions such as apartment housing and various types of employment (Zimmer, 1975). These change processes call for an increased understanding of recent developments in social status among suburbs.

The question of suburban stability versus change and decline has ramifications in urban sociological theory as well as in public policy. If suburbs do not change while their central cities do, this shows that the metropolis is not simply an expansion of the large city as previous theories stated (Banfield, 1970). Thus, the older theories of community growth and change are undermined because suburban stability equals nonchange in a major segment of the metropolis. In the policy realm, stability implies that the suburban belt will not suffer the long-run problems attendant upon status decline. Presumably central cities could continue to age and deteriorate and, perhaps, to become slums, while suburban persistence would guarantee a rosy future outside the city.

We suspect that recent studies found status persistence among suburbs because they employed deficient research designs. The first two suburban stability studies were based on panels of suburbs which appeared in the 1920 census (Farley, 1964; Guest, 1978). Using regression and correlation, Farley examined the bivariate relationship between high school enrollment in 1920 and adult educational attainment in 1960. Guest developed multivariate regression equations to examine the relationship between 1920 high school enrollment with 1950 adult educational attainment and the relationship between the 1950 variable and its 1970 counterpart. In both studies the educational indicators were used to represent community social status. The test of stability in these studies was the magnitude of the correlation coefficient between the status measurements at any two time points. The authors interpreted high correlations between scores at different times as representing status stability. The panel design excluded from consideration the massive suburban growth of recent decades. The panel design could not incorporate the growing new suburbs, including many high-status ones. Neither could it reflect the differential growth of new and old suburbs. Possibly the entire panel of 1920 suburbs was declining gradually in status, leaving room for new suburbs in the upper echelons. Thus, a better research design would consider population growth of existing places and include new suburbs.

The use of correlation coefficients within a panel also had a distorting effect in the Farley and Guest studies. Correlation does not offer the most revealing way to study suburban status over time. In a panel design the correlation coefficient cannot reveal upward or downward changes of the entire distribution. A downward trend of all the suburbs would be the same as subtracting a constant, and if the ranks were unchanged the correlation over time would be high. Two recent studies (Collver and Semyonov, 1979; Stahura, 1979b) introduced more complex regression techniques but, staying within panel designs, were subject to the same constraints as the earlier investigations. Furthermore, since status changes among subcommunities are likely to be small and gradual, a more sensitive measurement technique is required to detect them.

Another methodological deficiency in the literature is that city areas and suburbs are almost never studied together, even though the metropolitan community as a whole is a single status field. The social status of suburbs is related to the status of places in their central cities as well as to that of other suburbs.

The study which follows was designed

to test the hypothesis that the neighborhood life-cycle principle applies to suburbs as well as to city neighborhoods. We examined change in social status among suburbs in metropolitan Chicago, from 1940 to 1970. We devised an index of relative status for each census year and applied it in a cohort analysis to compare young and old suburbs. The index reflects changing city status, differential suburban growth, and the addition of new suburbs. The simple index, which can be presented graphically, reveals status change for individual places within the metropolis. The results show that status levels among subcommunities change constantly, although not necessarily rapidly, and that suburbs do pass through the neighborhood life cycle.

METHODS

An Index of Relative Status

Because social status among residential areas is relative it is best measured relatively. Individual members of the population of a metropolitan area have statuses and their localities have statuses based on the characteristics of their residents. These locality statuses are recognized within the population at large, as demonstrated by Felson's (1978) survey which showed that most individuals are able to rate suburbs in their own metropolitan area. This aspect of the suburban zone has long been recognized in sociological writings, certainly as far back as Whyte (1956), who noted that the young corporate employees in Park Forest aspired to more prestigious suburbs as they rose in their organizations.

By measuring status relatively, the analyst can make valid comparisons over time. Even if a place rises absolutely, say in educational attainment, if the general level of educations rises more, that place will fall in relative status. If a place stays constant in absolute status, it also falls relatively. A relative ranking also makes it possible to define cutting points consistently for strata or classes. For example, one might define the middle stratum as the middle third or the central two quartiles at each point in time and then look at the locational pattern of that segment. It becomes possible in this way to compare the location of the middle stratum at two different points in time.

Furthermore, as the status of localities exists relative to the old places, it is also affected by the statuses of newly emerging suburbs and by the differential sizes of places. Thus, if several new high-status suburbs are built, this changes the rest of the distribution. Likewise, if new, large middle-range suburbs enter the system or grow substantially, this affects the status distribution. So, a good measure of the relative status of places should take into account all the localities in the metropolis, and their population sizes, at the time of measurement.

We have devised a relative status scoring technique which treats city and suburban residential areas on an equivalent basis and takes account of the growth of the entire metropolitan system. It measures change in relative socioeconomic status of individual subcommunities and reflects shifts in the social status profile of the entire metropolitan area. Being weighted by population, it takes account of the differing sizes of residential areas and yields a single percentile score for each place at each time. Finally, the technique takes account of the addition of new suburbs and the differential growth of subcommunities within the metropolitan community.

We introduce three measures of status rank for each place. They are based on educational attainment of the adult population, the percentage of white-collar workers, and the median income of families residing in each place. Educational attainment has been used widely in urban ecological studies as an indicator of subcommunity socioeconomic status (Schnore, 1964; Farley, 1964; Guest, 1978). Schnore (1964) consistently used educational attainment as a proxy for socioeconomic status in his major studies of city-suburban status differences. Family income and occupational level are also conventional indicators of subcommunity status (see, for example, studies by Anderson and Egeland, 1961; Guest, 1974; Hunter, 1974a; 1974b; Rees, 1970; Timms, 1971). In the table and graphs which follow, the score based on educational attainment is called EDRANK; the income score is called INRANK; and the occupational score is called OCRANK.

Scores are generated by a cumulative percentage distribution in which each subcommunity receives a number between 0 and 100 indicating the percentage of the metropolitan population living in subcommunities scoring no higher. The N subcommunities are sorted so that the place with the lowest absolute status score (educational attainment, percentage of white-collar workers, or median family income) appears first in a list. The place with the highest absolute status score ends the list. The rank assigned to the M^{th} lowest subcommunity is:

$$\text{rank}_M = 100 \times \frac{\sum_{i=1}^{M} \text{Population}_i}{\sum_{j=1}^{N} \text{Population}_j} \qquad (1)$$

where Population_i is the population of the i^{th} lowest subcommunity.[2] Because formula (1) is weighted by population, it generates a percentile score for each place representing the percentage of the metropolitan population living in areas of equal or lower status. The weighting of places by population is necessary in the study of suburban social status because of the widely unequal sizes of suburbs and the mathematical effects of these differences. In metropolitan Chicago, for example, there are several small elite suburbs. Obviously such a cluster of cases with extreme values, unweighted, would distort the calculation of a mean across all suburbs. Similarly, a group of outliers would distort the calculation of a correlation-regression statistic.

The intuitive clarity of a single percentile number to represent the social status of a place at a point in time may be shown in an example. In 1940, Oak Park had a median educational attainment of 12.0 years, giving it a relative status score of 89.6, meaning that 89.6% of the metropolitan population lived in subcommunities with lower scores. By 1970, its median educational attainment was 12.8 years, which, in a study of absolute status would have appeared as a rise. But, as the educational level of much of the metropolitan population was rising rapidly, and as there was differential gain in status among places, Oak Park's relative status score dropped to 84.5.

Relative status, as defined in formula (1), computed for each decade, has several advantages for measurement and conceptualization. The educational and income levels of the entire metropolis rose from 1940 to 1970. Thus, a neighborhood with an unchanging absolute level of educational attainment necessarily fell behind other places. Relative status also permits a clear, convenient way to view different levels within the overall metropolitan community. One may define strata in some consistent manner—by deciles, standard deviations from the mean, or whatever—and then monitor particular subcommunities or particular strata over time.

In sum, the entire metropolitan area (Urbanized Area) is treated as a single field over which social status is distributed. New suburbs are added to the data base and relative status scores are computed for all suburbs, each decade. Community areas[3] and suburbs in each census year are ranked from bottom to top, regardless of city or suburban location. Each subcommunity receives a unique score at each time, which, because of its construction, can be compared with other places or with itself at some other time.

Cohort Analysis

In addition to measuring status, it is necessary to incorporate *time* into the analysis in order to evaluate the neighborhood life cycle model. It is necessary to measure the statuses of subcommunities at different points in their own growth cycles. This is readily accomplished by examining status at each census year. But, in order to cover the life cycle completely, it would be necessary to follow the status of each place for the better part of a century after it was built. This task would be exceedingly difficult and so the researcher must employ a design which simulates this history. Cohort analysis of subcommunities facilitates the examination of groups of places at different points in their histories and permits comparisons of the changes occurring among young and old places.

---

[2] Actually, an approximation or rounding error is introduced implicitly here when we represent the entire subcommunity by its median score. This is eliminated in part by replacing Population_M by $\frac{1}{2}\text{Population}_M$ in the application of formula (1).

[3] A Community Area is a district within the City of Chicago which has defined boundaries and a name. During the 1920s, Burgess and his students at the University of Chicago examined the city looking for areas with social homogeneity, common history, and boundaries. They divided the city into 75 community areas; data published in the Local Area Fact Books conform to these areas.

Research Site

Viewing the metropolitan community as an ecological entity composed of central city plus suburbs (Schnore, 1967), we defined the scope of the study as the 1970 Chicago Urbanized Area. We treated city Community Areas and suburbs as equivalent units of analysis (subcommunities), following the procedure introduced by Rees (1970). The population of the Urbanized Area grew substantially during the three decades studied; and the number of suburbs increased, as well. Data for the first year, 1940, included all 75 community areas and 57 incorporated suburbs with populations of 2,500 or more. City subcommunities are Community Areas, as defined by University of Chicago sociologists in the 1920s (Wirth and Furez, 1938; Kitagawa and Taeuber, 1963; Hunter, 1974b). In 1970, the city is divided into 76 such areas[4] which, in turn, are composed of census tracts. While the number of community areas remained constant, the number of suburbs grew; we added smaller or younger suburbs at later points in time when they reached 2,500 population and appeared in the census. By 1970, the Urbanized Area included 147 suburbs, with an aggregate population[5] of 2,579,802.

The basic data source is the United States census which provides small area statistics at ten-year intervals. Equivalent status measurements for city tracts and suburban places are not available for periods before 1940, so the time frame for the study is 1940 to 1970. Demographic measurements—such as numbers of persons by age, sex, and race—are available for all periods since 1920 but socioeconomic status variables do not appear until the 1940 and 1950 censuses.

TWO REPLICATIONS

Correlation within a Panel

It should be noted that our data set and status indicator could have been used to make an argument for suburban stability, had we employed the same type of analysis as did Farley (1964) and Guest (1978). Among Chicago suburbs, considering only the 57 suburbs in the 1940 census, the Pearson's correlation between relative educational statuses in 1940 and 1950 is .95; between 1940 and 1960 is .90; and between 1940 and 1970 is .89. Within the same panel of suburbs, the correlations for occupational rank are .96, .92, and .85, respectively, and for income rank are .78 between 1950 and 1960, and .68 between 1950 and 1970. These coefficients are extraordinarily high and might easily lead to a stability interpretation. The coefficients are approximately equal to those reported by Farley and Guest for postwar 20-year intervals. Those sociologists interpreted the high correlations to mean that the statuses of suburbs are stable over time.

But the remainder of our analysis shows that this is not the correct interpretation because most places are declining most of the time and because there are several types of movement taking place.[6] The correlation method of the earlier studies showed only that, relative to each other, the suburbs in the panel—which had to be older ones—retained their relative rankings. Within the entire suburban system they were not necessarily stable. Their ranks were not compared to newer localities in those inquiries. Furthermore, the movement, such as peaking and falling, entailed in status careers, could not be detected by the correlational method.

---

[4] The 76th community area consists mostly of O'Hare International Airport. In 1970, there were less than 1,000 residents of this area. We have omitted it from our analysis.

[5] Aggregate population in 1970 consists of the total population of all 147 subcommunities in this study. It is, therefore, less than the total population of the Chicago SMSA or the Chicago Urbanized Area.

[6] By examining series of status measurements for individual suburbs over time, we detected six types of sequences. A place may be stable, rising, falling, peaking, recovering, or zigzagging. Peaking places rise initially, hit a high point, and fall thereafter. Recovering places fall initially, then begin to rise in status. Zigzagging places continually switch directions.

Decomposition within a Panel

Collver and Semyonov (1979) have suggested that suburban social status has three dimensions rather than just the one—education—analyzed by Farley (1964) and Guest (1978). Collver and Semyonov measured change in income and occupational level in addition to educational attainment and concluded that there are different patterns of stability and change for each. In particular, they emphasized differences between income changes and changes in the other two dimensions.

While we were able to reproduce their findings among Chicago suburbs using unranked data, we found that income conformed more closely to the general pattern than it did in Collver and Semyonov's (1979) analysis of 89 Long Island suburbs[7] (see Table 1). We surmise that income appeared to be an anomalous variable in Collver and Semyonov's study because their measure failed to accommodate the fact that generally rising income levels necessarily brought increased variance in income among places.

Table 1. Components of Status Changes among Chicago Suburbs, 1960–1970*

Components	Median Years of School	Percentage White Collar Workers	Median Family Income
Change of mean	.140	.018	.875
Change of dispersion	.014	.000	.104
Positional change	.010	.052	.155
Dispersion and positional change	−.016	−.001	.071
Total change	.237	.070	1.205
N=	121	120	121

* This table replicates Table 3 in Collver and Semyonov (1979:484).

A factor analysis of our three status indicators among the Chicago suburbs revealed a nearly perfect correspondence among them (see Table 2). Furthermore, as will be explained later, the patterns revealed in Figure 4 show that all three dimensions of status behave quite similarly over time by cohort. Like the New York calculations, these factor loadings do show a somewhat lesser connection of income to the main factor, but even income has a very high loading which increases during each decade and reaches .92 by 1970. Thus, we conclude that, even though there are slight differences among the status indicators, the coincidence among them is so great that they are interchangeable.

---

[7] More specifically, our use of the Collver and Semyonov (1979:480–6) equation was as follows. We calculated the 1960–1970 total change and its components for the 121 suburbs of Chicago (there were only 120 for percentage white-collar). The measures of status were: Median years of school completed for the adult population (25 years or older), the percentage of the male population greater than 14 years of age employed in white-collar occupations, and the median family income in 1959 and 1969, in constant dollars. Our analysis shows about half the amount of total change Collver and Semyonov found in 89 Long Island suburbs. The four components of change—which sum to the total change—are also about half for our measure of occupational distributions. Chicago suburbs show several important deviations from the Long Island pattern. Educational attainment showed greater change in dispersion in Chicago than on Long Island by a factor of about 20.

Change in the mean is by far the largest component of change in median family income for both Chicago and Long Island suburbs. However, in Chicago it constitutes a larger proportion of total change (73%, compared to 58% in Long Island). The change in dispersion is small (9%) for Chicago but sizable for Long Island (32%); and positional change is moderate in Long Island (12%) but small in Chicago (4%). This paints a picture of a greater trend toward shared property in Chicago's suburbs.

The greatest similarity between Long Island and Chicago suburbs can be seen in the distribution of education. Here, the Chicago data showed almost exactly the same pattern of components of change as Collver and Semyonov found, although the Chicago figures are about half as large as the Long Island calculations.

Table 2. Factor Analysis of Status Indicators for Chicago Suburbs for 1950, 1960, and 1970*

	Loadings on:		
	Status 1950	Status 1960	Status 1970
EDRANK	.953	.925	.969
OCRANK	.989	.974	.958
INRANK	.831	.896	.921

* There is no factor called "Status 1940" because we have only two rankings for that year. Data on family income was first available for 1950.

RESULTS

Relative Status

Figure 1 shows the distribution of the relative educational status scores of a sample of places in 1940. Each black dot represents a suburb and each dash a city district.

Figure 2 shows the relative status scores for all the localities in the Urbanized Area 30 years later. Note that the educational level of the entire population rose (the "curve" shifted right) and that 90 suburbs were added to the system. The score of one of the examples, Oak Lawn, rose by 10.9 points, while Elmhurst and Berwyn lost 2.1 and 22.5 points, respectively, by 1970.

A comparison between Figures 1 and 2 shows that city areas which were in the middle and upper ranks in 1940 had drifted downward by 1970. Although there were numerous middle-level and a few upper-level city places in 1940, they had all lost status by 1970. Almost all of the popula-

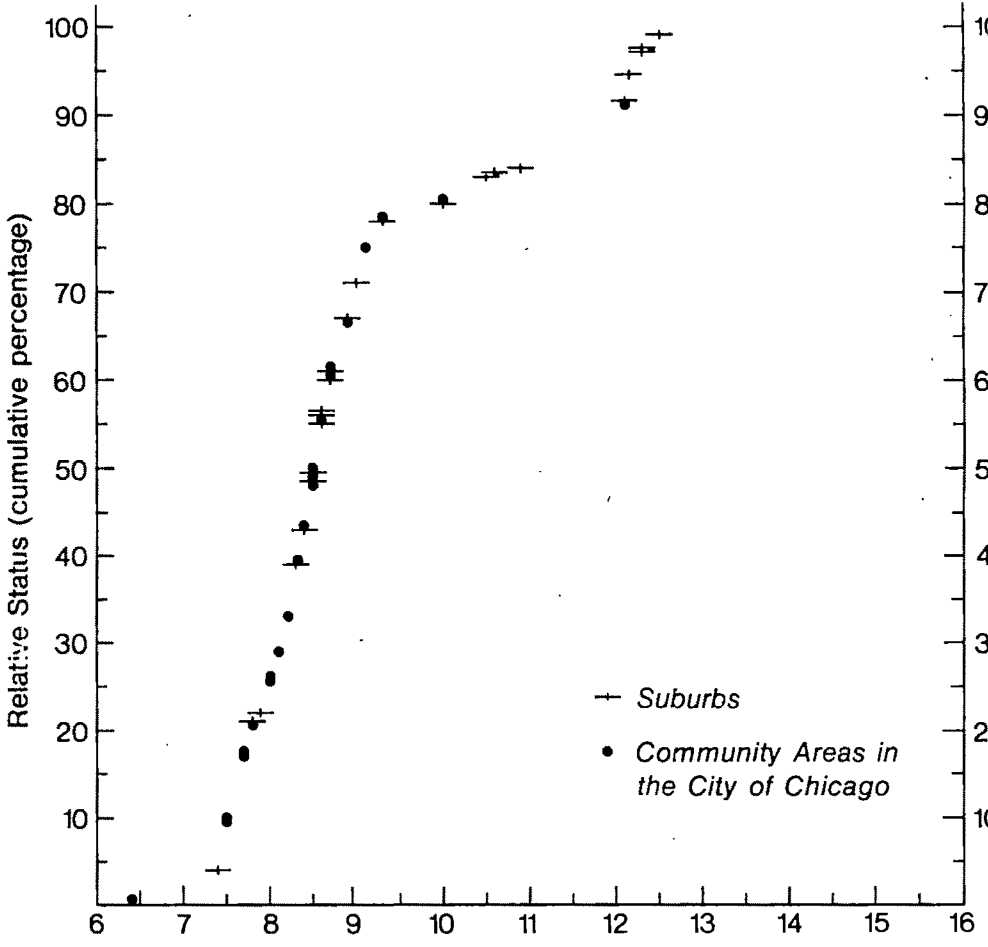

Figure 1. Educational Status Scores of a Sample of Chicago Area Subcommunities, 1940

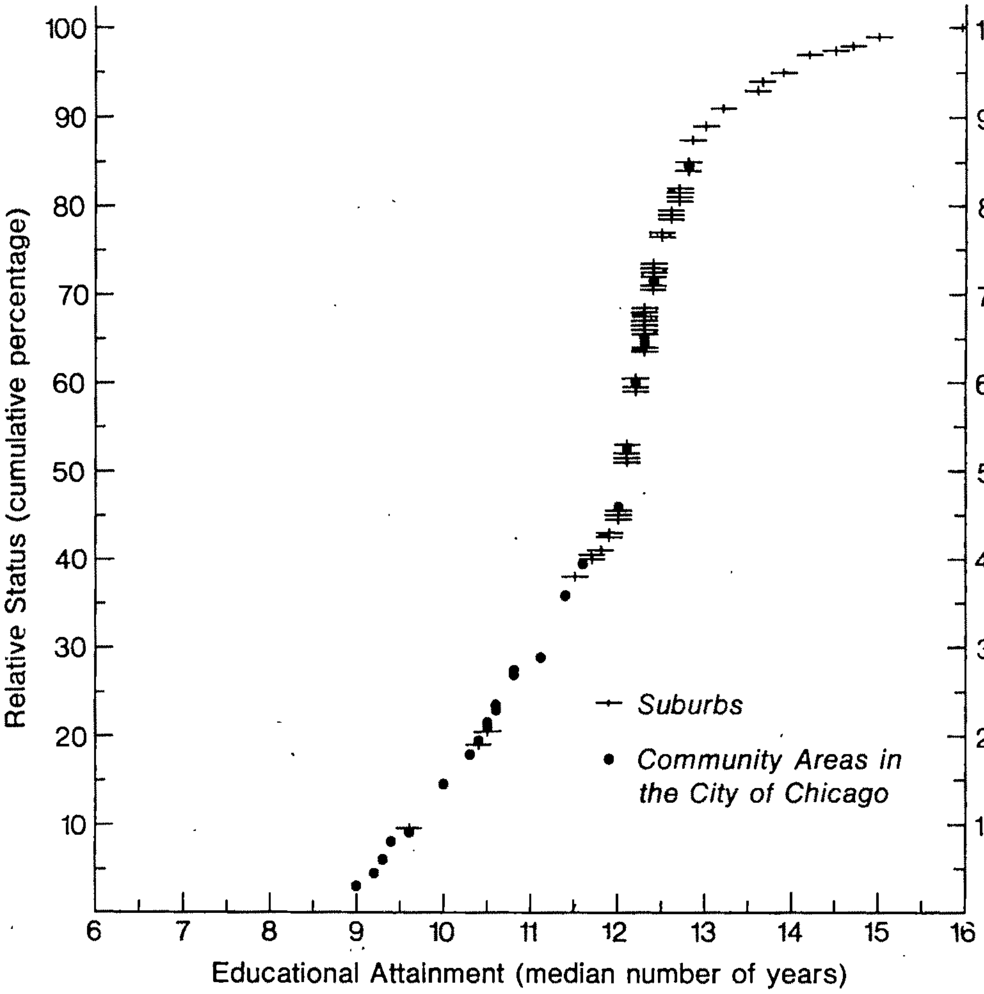

Figure 2. Educational Status Scores of a Sample of Chicago Area Subcommunities, 1970

tion of the upper strata and most of the middle strata lived in suburbs in 1970. In sum, Figure 2 shows that in 1970 most of the middle-strata places and all of the elite places in the Urbanized Area were suburbs.

Another way of seeing the status shift during this period is to compare the average scores for city areas and for suburbs in each census year. Table 3 shows that, in 1940, the average suburb had considerably higher status than the average city area. This was true for all status dimensions. This differential increased over the following decades as the city average dropped. The only exception was that suburban income status, already much higher than the city's, failed to rise in the 1960s.

Cohort Analysis

Placing the subcommunities in cohorts allows a different interpretation of the high status suburb and low status city area split. Sixty-three of the 75 city neighborhoods are in the cohorts born before 1940, while nearly all (48 of 57) of the suburbs were born after 1940. Plotting the mean weighted rank scores of the six cohorts of suburbs from 1940 to 1970 reveals the typical life cycle pattern of rise, peak, and decline (see Figure 3).

To conduct a cohort analysis, we first determined the time at which each subcommunity was built[8] and assigned each

---

[8] Duncan et al. (1962) and Guest (1973) use a criterion of two dwelling units per acre to indicate when a census tract was built. (This would have been a

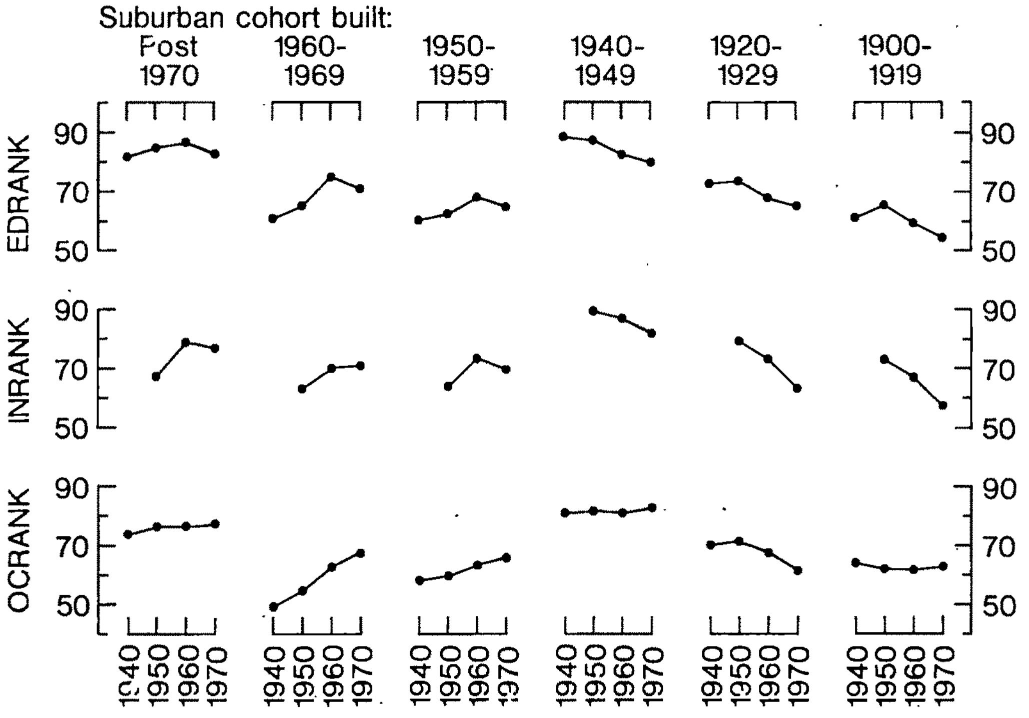

Figure 3. Mean Rank Scores among 6 Cohorts of Suburbs

place to a cohort, similar to a birth cohort in demographic analysis. We measured the relative status of each subcommunity at four census years and combined these scores into means for cohorts. We then followed the status changes of cohorts. This allowed us to compare the 30-year changes of old subcommunities with those of young subcommunities, to see both types behave as the life cycle model would predict. Our cohort analysis follows the procedure recommended by Guest (1974:230–1). There are six cohorts among the Chicago suburbs: those built before 1920, those built in the decades of the twenties, forties, fifties, sixties, and those which had not crossed the specified density threshold by 1970.

Table 3. Weighted Mean Rank Scores, Chicago Community Areas and Suburbs, 1940–1970

	EDRANK		OCRANK		INRANK	
	City Areas	Suburbs	City Areas	Suburbs	City Areas	Suburbs
1940	46.2	68.4	47.1	64.2	—	—
1950	44.6	70.6	46.0	65.3	44.3	70.2
1960	38.0	73.7	41.7	66.3	38.0	73.7
1970	33.9	70.8	35.7	68.9	32.7	72.4

Notes: Each entry represents the mean score for localities, either within the city or the suburban zone. The means were computed after the localities were weighted by their own populations. For example, the table shows that in 1960, the mean EDRANK for all city community areas was 38.0. The combined weighted mean rank score for city and suburban localities, pooled, is always 50.

There is no INRANK score 1940 because the census did not give family income then.

Suburbs of the two oldest cohorts, built prior to World War II, peaked in status in 1950 and declined gradually in each of the successive decades. They followed this pattern in each dimension of status: educational attainment, occupation, and income. Suburbs of the 1940s followed the same pattern as the prewar places except that their educational status peaked earlier.

---

dwelling-unit density of 1,280 per square mile.) We approximated their procedure with larger areal units, using a criterion of 1,200 dwelling units per square mile.

Cohort was coded by the last two digits of the year in which the place crossed the density threshold. For example, places built up between 1920 and 1930 are coded "20" and places born between 1950 and 1960 are coded "50." Areas built up in the nineteenth century are coded "01." This coding scheme means that young places have high scores and old places have low scores.

Table 4. Mean Weighted Rank Scores of Chicago Suburbs, 1940–1970

	Cohort built:						
	1900–1919	1920–1929	1930–1939	1940–1949	1950–1959	1960–1969	After 1970

1960	66.9	73.1	—	86.7	73.4	70.3	79.2
1970	57.3	63.5	—	82.0	69.8	71.6	76.5
Number of suburbs:	2	7	0	4	15	14	15

Younger suburbs, on the other hand, rose in their early decades. Those built in the fifties and sixties tended to peak by 1960 and then to decline somewhat in educational and income status. They did, however, continue to rise in occupational status through the 1960s.

The overall pattern, over time, in each of the status dimensions, is that of the neighborhood life cycle. This can be seen by reading each of the horizontal panels in Figure 4 from left to right. Older cohorts of suburbs tend to decline in status while young cohorts of suburbs tend to rise.

DISCUSSION

We found that suburbs do change in status over time, typically moving gradually downward. This change is a function of the age of place. The general pattern of change resembles the neighborhood life cycle.

Methodologically, we have demonstrated a way to compute status scores for subcommunities, incorporating city districts and suburbs within a metropolitan area. These scores facilitate comparisons over time. We have used this technique to reveal changes in suburban status as the housing stock in the suburb ages.

Had we simply followed a panel of suburbs and correlated their absolute status scores over time as Farley and Guest did, we would have found high correlations, as they did. But the new scoring procedure clearly shows change in suburban status.

Thus, we reject the persistence-stability hypothesis in favor of the neighborhood life cycle. This conclusion is consistent with older sociological theories of subcommunity change. We conclude that the suburban analysis does not show status stability and that the great majority of suburbs is subject to the neighborhood life cycle. Suburban housing ages like city housing and, as this happens, the relative status of places declines. The only reason the life cycle has not become obvious outside the large cities is because most suburban environments are relatively young. Nonetheless, we are convinced that suburban communities are not immune to the ravages of time. Like other urban subcommunities, they must discover ways to renew themselves or give way to processes of decline. A casting-aside of the persistence-stability hypothesis allows us to look directly at the macroscopic urban community changes in progress and at their implications for urban theory.

As the metropolitan areas of the midwestern and northeastern United States enter a new era of nongrowth, the dominant models of urban growth and structure need major revisions, especially insofar as they attempt to explain change at the subcommunity level. For perhaps 20 years after World War II, urban population growth continued apace, as peripheral suburban growth overbalanced central-city losses. By 1970, though, many central cities had small net losses. Thus, the era of growth had ended for them. The succession and neighborhood life cycle models were predicated upon physical growth of the community so that as the occupants of a neighborhood rose in social status, they could move on to a newer, more desirable residential environment.

Now, however, there are developments which promise to curtail the construction of new peripheral residential areas. Proponents of the "no-growth" ideology often successfully prevented residential expansion (Frieden, 1975) and city planners generally oppose continued "suburban sprawl." The national constraints on energy consumption are also likely to prevent further suburbanization because of the high automobile usage in such areas. Therefore, metropolitan communities are likely to be spatially confined to their current areas.

If this occurs, the continued operation—on its old terms—of the neighborhood life cycle will be impossible and some alternative will emerge. This could take the form of a status freeze whereby areas are maintained at current levels, contrary to the historic pattern. The new model might include high-status redevelopment in old city centers, also contrary to the United States historic model. Or, it might result in some pattern which is simply not now anticipated.

GENERATING NEWSWORTHINESS: THE INTERPRETIVE CONSTRUCTION OF PUBLIC EVENTS*

MARILYN LESTER
University of Nevada

American Sociological Review 1980, Vol. 45 (December):984–994

Everyday life is not organized a priori as discrete public events which can be simply mirrored by newsworkers. It does not differentiate itself into newsworthy events for reporting and publication. News is a product of reality-making activities and not simply reality-describing ones. A critical sociological task is to examine newsworkers' transformations of the everyday world into published or broadcasted events-as-stories (Molotch and Lester, 1974; Tuchman, 1972; 1973a; 1973b; 1976; Glascow University News Group, 1972; Cohen, 1972; Cohen and Young, 1973). This paper details one core aspect of this process, the routines newsworkers use to identify and display the newsworthy character of occurrences and events.[1] Historically, newsworthiness has been viewed as a property of events in an external social order. Relying on primary and secondary data collected in several news organizations, an alternative conceptualization, consistent with basic tenets of ethnomethodology, is provided in this paper. Here, newsworthiness is an actively generated feature of events.

CASE MATERIALS

The principal data for this project were collected in 1972 while I was a participant observer at a large national and international newspaper, referred to as "*The Interpreter*." Its owner is an international organization, referred to as "Organization," which is based in a major metropolitan area.

The major components of *The Interpreter* are American News and International News. Each has an Editor and support staff in the newsroom while subordinate Bureau Chiefs and reporters are geographically dispersed throughout the world. The local news bureau, here called "Regional Bureau," is officially part of American News.[2] In conjunction with great stipulations, I was assigned to Regional Bureau as an intern reporter. Apart from the practicality of focusing data collection there, it was observationally strategic in that it was the only bureau with a full complement of staff in the newsroom. Additional sources of data at *The Interpreter* included: the American News desk where I spent two weeks; outside the newsroom, tracking camera crews and both City Hall and Suburbs reporters on their work routines; the City in general—covering stories, conversing with news sources and newsworkers from other media; and attending official meetings of the whole Organization staff.

While there was variation in the type of materials collected at *The Interpreter*, a single case is insufficient for developing durable theory and specifying the conditions under which various features of a process occur and/or assume different forms (Glaser and Strauss, 1967; Bigus et al., 1978). Therefore, in the summer of 1974, further observations were collected in seven media organizations in a midwestern city: the only daily newspaper,

The Russell Sage Foundation assisted in the support of this project and obtained my entry into a major newspaper. I wish to thank Carolyn Mullins for her editorial assistance, Allen Grimshaw, Stuart C Hadden, Candace West, and several anonymous reviewers who read earlier versions of this paper and gave helpful comments.

[1] Throughout this paper I adopt Molotch and Lester's (1974:101–3) conceptual distinctions between happenings, occurrences, and events.

[2] Officially the Regional Bureau Editor is delegated his authority by American News. In practice he operates semiautonomously. Regional Bureau has control over its own pages in the Regional Edition of the paper, although some local stories are selected for publication in other regional editions, in which case the American News Editor has control of the story.

the University News Bureau, an "alternative" weekly paper, two AM radio stations, one FM radio station, and a local television station.

A third source of data is used: other sociologists' ethnographic descriptions and analyses of newswork routines, particularly the work of Tuchman (1972; 1973a; 1973b; 1974; 1976).

TRADITIONS IN THE STUDY OF NEWSWORTHINESS

Newsworkers view their work in terms of *selecting* the most important events, and portraying those in an interesting and informative way. Journalists' conceptions are paralleled by the dominant sociological perspective—gatekeeping (cf. White, 1950; Gieber, 1956; Carter, 1959; Schramm, 1960; Buckalew, 1974; Harless, 1974; Janowitz, 1975; Whitlow, 1977)[3]—which suggests that events are successively filtered through a set of news gates. Official and unofficial (but, nonetheless, literal) values, norms, and rules constitute a template against which events sui generis and stories portraying those events are measured for their newsworthy character. A number of scholars (Halloran et al., 1970; Glasgow University News Group, 1972; Cohen and Young, 1973; Galtung, 1973; Hall, 1973a; 1973b; Phillips, 1973; Young, 1973) have modified this perspective by showing that political ideologies and historical circumstances form an inferential structure for selecting and interpreting events.

However, in both its limited and broader forms, gatekeeping is a substantive application of a paradigm which views social action as primarily deriving from actors' orientation to, internalization of, and enactment of values, norms, and rules (see Wilson, 1970; Wieder, 1974). To be more than merely sensitizing—that is, to be empirically accurate and logically adequate, the "news gates" must be clearly identifiable and available for *literal* description in the career of an event. Moreover, their meaning and applicability would have to be specifiable prior to use as a template for gauging newsworthiness.[4]

If these conditions are not met, a core variable other than gatekeeping is required to explain the process by which journalists identify the newsworthy character of occurrences, events, and stories. My research points to the availability of such an alternative: an ethnomethodological perspective on the process of identifying and displaying newsworthiness which I term "generating newsworthiness."

GENERATING NEWSWORTHINESS

Talk about newsworthiness is a commonplace newsroom activity. From newsworkers' and gatekeeping theorists' standpoints, such talk merely reports on or reflects social reality.

However, when the talk-world dichotomy is analytically suspended, an alternative perspective is made available to the sociologist.[5] Accounts of newsworthiness do not present reality; rather, they forge it. They are one crucial set of practices for *managing* newswork routines.

Articulating particular occurrences, events, and stories with accounts of newsworthiness is not a literal application of a priori rules or news norms to specific situations. Whatever the inherent structures of occurrences might be, what they will have come to as newsworthy events are socially and situationally organized. Generating newsworthiness is a *reflexive* process whereby: (1) accounts of newsworthiness organize and give meaning to occurrences as events and stories;

---

[3] In fact, the central concern of sociologists since World War II had not been with newswork processes at all but, rather, with either the content of media or the consequences thereof. It is quite possible that the fundamentally ambiguous—and even conflicting—findings about media bias and effects are due to a flawed (or at least highly oversimplified) view of news production (see Shibutani, 1966:130, 169). Essentially an input-output conception (cf. Lasswell, 1971; Wright, 1959) has operated in the majority of research.

[4] Wieder (1974) discusses similar analytic requirements for behavior in general to be viewed as rule-governed.

[5] For important discussions of the distinction between topic and resource, see Garfinkel (1967), Zimmerman and Pollner (1970), and Hadden and Lester (1976).

(2) accounts of occurrences, events, and stories elaborate the meaning of accounts of newsworthiness; and (3) the preceding items (1) and (2) are used to display newsworkers' professional and rational methods for doing their work.

Generating newsworthiness is always grounded in some particular news project. So, as practical projects change, so do the form, content, meaning, and practical consequences of accounts of newsworthiness. Moreover, when newsworkers generate competing accounts of newsworthiness, they are not, in fact, constructing competing accounts of the selfsame social object. The following excerpt from field notes (Lester, 1974) at *The Interpreter* is one example:

> (I) In the first week of my research, I was asked to cover a protest against the Vietnam War staged by school teachers at the site of local war industries. The story was written as an "interpretive" article where the particular occurrence illustrated a basic change from a student-centered national movement to local-centered protest by nonstudents. When the story was completed and scanned by the Editor, herein called "Rex," he took me and my story to the People Reporter (a news "beat" within Regional Bureau) who usually does most of the "protest reporting." She said *The Interpreter* had done several pieces on the war. What I should do, she said, was focus on the question, "What is business's response to war protestors?" Then she said there already were articles which reported change in the protest movement—its decline. I claimed we were talking about two different kinds of change. Rex told her that material about business belonged in a separate article, that this story deals with the meaning attached to the protest by the protestors themselves.

Rex's initial project, informing the People Reporter about a story he perceived to lie in her area, faded when seemingly incompatible accounts of newsworthiness were employed. In so doing, the newsworkers actually created multiple events[6] (for example, declining protests, transformation in protest form, the subjective meaning of protest).

Organizational Variation in Generating Newsworthiness

Accounts of newsworthiness constitute a dominant focus for newsroom interaction and are central to an explanation of newswork routines at *The Interpreter*. Yet, they are not detailed in other research on newsmaking processes. Instead of simply assuming oversight by others, I compared others' ethnographic descriptions of research sites and published reports with my own data to discern the organizational features and/or newsworker orientations which might constitute conditions under which generating newsworthiness is a central *newsroom routine*.

I found two patterns in the relationship between organizational features surrounding newswork and the general way in which generating newsworthiness occurs, displayed in Tables 1 and 2.

At issue in this comparison is not *whether* generating newsworthiness occurs but *where* it occurs as a routine interactional focus—that is, "on the beat" vs. "in the newsroom." For personnel working in media organizations oriented to break occurrences, accounts of newsworthiness are constructed routinely among those sharing a beat and in the newsroom only where *particular* cases are *typified* as problematic. At other times, with an orientation to "quickening urgence," workers identify their paper simply as "a newspaper," "a paper of record," "we cover important and interesting events"; or they categorize occurrences as certain types of events—for example, "hard," "soft," "developing" news, etc. (Tuchman, 1973a). When such categories

---

[6] That competing accounts proffer different social objects is not unique to newswork. Pollner (1970; 1974a), for example, examined how traffic court judges adjudicate accounts of District Attorneys, police, and defendants. The adjudication process constitutes the seen-but-unnoticed procedures through which mundane inquiry's commitment to "objective reality" is displayed and sustained. Similarly, Bittner (1967), Cicourel (1968), Zimmerman (1970a; 1970b) and Wieder (1974) point to a similar property of accounts in their respective analyses of how police on Skid Row, probation workers, welfare agency personnel, and residents and staff of a halfway house attend to, and make sense of, apparent contradictions in their rule use, and thereby simultaneously provide for their competent (for example, rule-governed) performances "for all practical purposes."

Table 1. News Media Organized to Cover Breaking Occurrences

Organizational Feature	News Orientation
1. Paper oriented to supplying news on breaking events (Tuchman, 1973a).	1. Principally *identifies itself* as supplier of metropolitan news. What counts as news is not made routinely problematic.
2. A majority of the paper is devoted to metropolitan news. Reporters write at least one, often several stories per day.	2. Reporters spend relatively little time on each story. "Quickening urgence" is the orientation to newswork (Tuchman, 1973a). Occurrences are typified on the basis of the need to manage the flow of work, in particular, to manage occurrences that are "specifically unforeseen." Newsworkers typify and distinguish "hard news," "spot news," "soft news," "continuing news," and "developing news."
3. Reporters have fixed "beats"—e.g., City Hall, Police. Some of these are subdivided into even more specific beats. Reporters spend most of their time at the location of their beats. Reporters from ostensibly competing media who share a beat spend both professional and informal time together.	3. The beat location is the primary site for generating accounts of newsworthiness. Accounts of newsworthiness are routinely produced as an *interorganizational* activity—i.e., among those sharing a beat. In the newsroom, generating newsworthiness occurs when a particular case is typified as problematic.

are assumed to have shared meaning, they are constantly available as a general gloss of newsworthiness to manage the flow of work. However, Garfinkel (1967), Zimmerman (1970a; 1970b), Cicourel (1974), Wieder (1974), and Hadden and Lester (1979) have shown that people in the world of daily life (including reporters and editors) perform cognitive and interactional work to sustain and display the sense, "I know what *that* (for example, an identification of newsworthiness) means" so that a specifically vague account is allowed to stand without notice or breaching while other practical projects are undertaken (for example, working on the beat, generating newsworthiness with reporters sharing a beat).

The orientation to quickening urgence is not the organizational basis for *Interpreter* newswork. Newsroom personnel did not use the same typifying scheme as did Tuchman's subjects for carving the world of occurrences into newsworthy and nonnewsworthy events, which contravenes any generic status for her (Tuchman, 1973a) conceptualization of newsworkers' typifications of news. Generating newsworthiness occurs routinely as an *intra*organizational activity. Glosses of newsworthiness are replaced by the *interactional* production and display of newsworthiness at multiple points in news production. Instead of hard vs. soft news, etc., the issues related to identifying newsworthy and nonnewsworthy occurrences-as-events and stories are of the sort: "What, in general, should we be looking at?" "Is it newsworthy?" "What kind of coverage should be given?" and "How can we make this story different from other medias' accounts and meaningful to the reader?"

One indicator of this variation is that several staff moving to *The Interpreter* from metropolitan media encountered difficulty in changing their work routines with regard to the specific organizational features described. A second source of verification of the different loci for generating newsworthiness comes from data (collected in other media organizations) which turn out to lie between the two ideal types depicted.

FRAMING THE ORGANIZATION, NEWS NORMS, AND STORIES

Generating newsworthiness can take three different forms: (1) Framing the

Table 2. The Interpreter: An Example of a Multifocused News Media

Organizational Feature	News Orientation
1. Stories on breaking occurrences typically appear at least one day later than in newspapers organized to cover breaking events.	1. No one definition of the newspaper's function pervades. What counts as news is made routinely problematic. The "real status" and "real meaning" of the paper, news, and newsworthiness are identified in different ways on different occasions.
2. A maximum of two pages of the Regional Edition of the paper is devoted to regional news, most of which is City-related. Reporters write no more than three stories per week.	2. Reporters spend a lot of time on each story—finding topics, discussing details with colleagues, etc. The newsroom has an ambience of casualness; "quickening urgence" is rarely an orientation. No one typifying scheme is used by workers to manage the flow of work.
3. "Beats" are generalized roles[7] (e.g., Environment, People, Suburbs) which change with *Interpreter* and Organization goals, personnel, and current news themes. The only conventional beat is City Hall, to which one reporter is assigned. Reporters spend much of their time in the newsroom. Due to the features outlined above, reporters have no counterpart in other media organizations and eschew such contact.	3. The newsroom is the primary site for generating accounts of newsworthiness. Generating newsworthiness occurs as an *intraorganizational* activity. *Interpreter* personnel are consistently available to each other for, and are oriented to, identifying and displaying newsworthiness as a routine feature of newswork.

Organization, (2) Framing News Norms, and (3) Framing Stories. Each form can be readily identified as an interactional focus in specific situations and each has distinct consequences for newswork.

Framing the Organization

Tables 1 and 2 show that organizational features and organizational context—as defined and accounted for by members of news organizations[8]—make a crucial difference in the news process. As such, persons' accounts of organization are an important component of generating newsworthiness.

These organizational accounts which I term "framing the organization" may, in a direct way, socially organize and give meaning to occurrences (for example, as newsworthy events or not) as well as assemble their specific features (for example, what will be taken as features of occurrences and their ordering into a coherent pattern). As such, this form of generating newsworthiness is integral to newswork—in fact, occurring within the stream of ongoing newswork activities. The following excerpt (Lester, 1972) illustrates this relationship between accounts of organization and newsworthy occurrences.

> (II) During a portion of weekly Regional Bureau staff meetings, methods for covering various occurrences are discussed. In one such session, the topic of water fluoridation arose which one reporter then abruptly closed: "The [Organization's] interest in fluoridation is declining. . . . The people behind antifluoridation are crazy. . . . I don't want to get involved. . . . The arguments are extreme."

Here, framing the organization is used as an embedded interpretive device for making sense of an occurrence. Reciprocally, the account of the occurrence elaborates the meaning of the organization as formulated.

---

[7] Hughes (1940) shows that specialized feature topics are also carved out as beats in metropolitan newspapers. The difference is that these were the primary type of role at *The Interpreter*.

[8] More generally, Bittner (1965) suggests that a person's "concept of organization" is used as an embedded organizational resource to manage work routines.

On other occasions the connection between framing the organization and the very practical routines for putting out the paper are more opaque. Accounts of organization often serve as a reminder to one's self about the status and meaning of otherwise "seen but unnoticed" newswork practices. Only upon such a reflective glance, entailing a shift of attention from the immediate practical task at hand, are social actions (for example, newswork strategies; either meaningful or discernible as a series of discrete activities (cf. Schutz, 1962). The next illustration (Lester, 1974) comes from the alternative newspaper in a midwestern city. In this case, a concept of organization in terms of intended readers is used to "make sense" of particular newswork strategies:

> (III) "We appeal to people in and around the University rather than to the general townspeople or to just students exclusively. . . . We appeal to students who aren't into all the campus activities. . . . The main thing that we do that is different is that we spend more time researching topics and more hours with the people we're writing about. Most papers don't have the time to get the real facts. . . . We usually do more than interview and try to follow a scene all the way through to find out what's actually happening."

Finally, framing the organization may occur outside any specific newswork situation and function to identify or formulate the organization per se. The illustration (IV), following, comes from field notes (Lester, 1972) taken at a formal meeting of all Organization workers (that is, *Interpreter* and all other Organization personnel).

> (IV) The Editor of *The Interpreter* spoke first. He said the paper as a whole including the editorial pages has a concern with healing: "If you could see a theme, it would be a responsiveness to good." Then he said the goal of [*The Interpreter*] was problem solving. He noted three phases in journalism: "(1) fact reporting, (2) interpretive reporting, and (3) what to do about the situation. And [*The Interpreter*] has led the last two phases of journalism." Another speaker was the Syndication Editor who selects *Interpreter* stories for sale to other subscribing media. He said the syndication activity is a "mission mandated by [the Founder of Organization] by virtue that [Founder] said. . . ."

Three distinct concepts of organization are provided: having a healing effect, leading the last two phases of Journalism, and syndication being an organizational mission. Each account offers a scheme of interpretation for understanding one's everyday activities and each elaborates the meaning of the others.

One additional feature of this form of generating newsworthiness is also frequently present, either explicitly or implicitly—subjective evaluation of the organization. The illustrations above could imply that framing the organization consists solely in accounts which proffer the "*good* sense of what we do." Though not occurring frequently in the data, there can, of course, be negative organizational accounts which have the same formal structure and practical consequences as other accounts, varying only in content.

Framing News Norms

Framing news norms is the situated identification and display of news criteria. Accounts of news norms are rules-in-use. They inform the organization of, and give meaning to, the situation at hand (for example, producing stories at some point or providing for the competent character of a particular newswork strategy, etc.). At the same time, the situation *as attended to* elaborates the news norm. An excerpt from field notes (Lester, 1972) taken at *The Interpreter* illustrates:

> (V) The Clerk for Regional Bureau typically assembles one part of the Regional Pages—a relatively large "box"[9] containing both original short articles and rewritten wire service material. While doing this one afternoon, she looked up and said, "You throw away car crashes, murders, throw away anything that has a really negative tone—like fires, accidents, things like that." At this point, Rex interrupted: "Some things can be newsworthy. *Keep the sensationally nega-*

---

[9] A "box" is a story set off on the page by enclosing the entire story or stories within 4 bordering lines.

> *tive*. When in doubt, you throw it to the Editor." While Rex went back to his work, the Clerk's conversation continued: "I throw the majority out. Certain times when I'm not sure, I save it and show it to the Editor."

In excerpt (V), the Clerk frames a news norm for doing one part of the local section of the paper—for example, throw away anything that has a negative tone. Neither she nor anyone else ever supplied a more specific set of criteria for gauging "negativism" (or any other news norm for that matter). Rather, we find her bringing substantive examples of the phenomenon ("fires, accidents, things like that")—to bear on the essence of the norm. Such examples do not merely illustrate a preestablished or clearly specified news norm. As a routine property of this form of generating newsworthiness, they are devices used by speaker and hearer to extract the situated essence—the substance, applicability and meaning—of the news norm in a particular situation. And, reflexively, the news norm as formulated identifies the situated essence of the examples—for example, fires are here assembled as instances of negativism. (Fires can also be attended to as instances of other kinds of occurrences.) The reflexive tie between accounts of news norms and examples provides persons with a resource to perform needed "ad hocing" work (Garfinkel, 1967:20–34), filling in unstated, but assumed, meaning that each can use to provide the sense, "we understand what newsworthiness is—for the time being."

A further analytic feature is illustrated in (V) above, the essential incompleteness of all news norm accounts. Rex apparently sensed the incompleteness and possible misunderstanding of the Clerk's first account of negativism, and he attempted to repair the situation ("*Keep the sensationally negative*.") However, this "exception" to the rule renders it no more a "news gate" than before, for it is itself specifically vague. As a repair, it sufficed only for the moment. Subsequently, the Clerk uses the Editor's "exception" as her resource to extend and, from her standpoint, to repair the previous formulation—for all practical purposes—for example, to display her competence as a newsworker, as well as to provide practical understanding for me. However, there can never be enough elaboration for the news norm to become a literal description of newsworthiness—that is, to clear up its indexical or context-sensitive nature (see Garfinkel, 1967:4–7). In none of these data is there a bottom-line, once-and-for-all framing of any news norm, only formulations that manage the practical circumstances at hand.

The reflexive pairing of news norm and examples is one method persons use to identify and display newsworthiness. A second method uses persons' accounts of the good and sensible "*reasons*" for a news norm. The following is illustrative:

> (VI) In a conversation (Lester, 1972) with Rex, he said reporters look for "an angle" or "a different context" for their reports.[10] That is, they have to "make the story relevant" because of the "time problem" (see Table 2: Organizational Feature, part 1). I asked him if he thought he missed important stories because of the time lapse between the occurrence and publication of stories. He said, "Yes," and immediately provided an example: "George Wallace was shot about 3:30 on a Monday afternoon. A small box was written by 4 p.m. The next day there appeared 'interpretive stories.' "

First, a general news norm is offered. Then, Rex details the reasonableness of the norm: structural contingencies inhibit timely coverage of breaking events. Generally, the data suggest accounts of structural contingencies to be a common type of "reason" offered for a news norm along with accounts of events in which values and personal tastes are imputed to both consumers and news organizations (in excerpt III, quoted earlier). It may appear that these reasons are merely justifying statements as described by Mills (1940) and Scott and Lyman (1968). While they may justify news norms, they are also important for newsworkers' identification and display of the essential meaning and practical uses of the news norm. When disparate accounts of "reasons" are provided, the content, meaning, and uses of a news norm are fundamentally different.

---

[10] "Making a story relevant" by "finding an angle" was an important news norm. In the absence of an alternative to focusing solely on hard news or "breaking events," a more serious trouble in self-identification as a news organization would result: old news is no news. Finding an angle is used as a practical, though fundamentally interpretive, solution to that quandary.

As an empirically and logically related matter, if the "same" occurrence is depicted through different news norms, multiple public events are thereby made available. For example, Rex did not frame the "negativism" in the assassination attempt on Mr. Wallace in case (VI) above. Rather, these occurrences were used to render the meaning of a different news norm (that is, "finding an angle"). As an observer, however, I saw potential contradiction with the "negativism rule" and questioned the Clerk (who had been present during the interaction in [VI] above:)

> (VII) He said, "[*The Interpreter*] doesn't cover negative things." I raised the point of the assassination attempt on Mr. Wallace. He said, "Yes, that got covered, but *in the context of gun control*" (emphasis added).

At this point, the Clerk totally reframes the occurrence and how it was covered—that is, the occurrence is now an event documenting the need for stricter gun control. In effect, his account neutralized a reasonable observation of contradiction and created consistency between the news norm (negativism) and a possible violation.

Framing news norms has analytic consequences, as well as practical effects, for any conception of newsmaking. A simple gatekeeping perspective requires, first, that rules be specifiable prior to their use as a template to gauge newsworthiness and, second, that rule application be fundamentally independent of the situations being attended to under the rubric of any particular rule. My data suggest that these requirements are not met empirically, nor can they be met. Occurrences are not prepackaged "out there" and then selected by a finite and literal set of news norms. Nor is framing news norms just an intermediary stage or "gate" in newswork: (1) here's the world of occurrences, (2) here's the news norms, and (3) here's the final events-for-reporting. Rather, this process essentially provides embedded instructions (see Wieder, 1974) for socially organizing and giving meaning to newswork strategies as well as to occurrences, events, and stories.

Framing Stories

The focus of framing the organization and framing news norms is the situated construction and use of schemes of interpretation for managing newswork. Complementing that focus, framing stories involves the use of accounts of newsworthiness to render *particular occurrences as public events*. As such, this form of the process has a thoroughly practical orientation.

Framing stories includes accounts which assemble the overall newsworthy character of particular occurrences. Or a newsworker may show how an occurrence is not a newsworthy event and will not result in a good story. These types of accounts are illustrated in excerpts (VIII) and (IX) (Lester, 1972):

> (VIII) The Clerk for Regional Bureau had been assigned to write a "wrap up" (summary) of college commencement exercises. He looked up at Rex and me at one point and initiated a conversation:
> Clerk: Commencements are so boring.
> Rex: Maybe work out a "box," what speakers are saying.
> Clerk: I don't think there's any common thing as far as I can see.

> (IX) The Suburbs Reporter came over to Rex's desk: "I don't think I have a story here. The City *always* rejects bonds for new schools."

Without knowing "the facts," Rex identified commencement exercises as one coherent event-for-reporting in (VIII) above. With an alternative account of newsworthiness, there may have been several separate stories. Or, without this interaction, there would have been no story since the Clerk identified commencements as "boring"—that is, nonnewsworthy. Each account frames "commencements" into a different patterned event-for-reporting—or nonpattern (that is, no "common thing") as in the Clerk's second account proffering the absence of a newsworthy story. However, when an account of some occurrence proffers too much typicality, it becomes nonnews. This occurs in excerpt (IX) where the rejection of a school bond initiative is seen as "just" an instance of a type which "everyone already knows" (see Schutz, 1962:3–34).

Framing stories is not a literal description of occurrences. Rather, it is an interpretive device for actually assembling the essence of the occurrence, as well as the written depictions thereof, as the next two excerpts (Lester, 1972) show.

> (X) Rex and a reporter had been talking about a state official vetoing a City redevelopment project. The reporter had talked about his plan to cover "both sides" (that is, State vs. City). Rex responded:
> Rex: I'm concerned with the whole philosophy of urban renewal, that what we're doing is leasing large parts of the city to large financiers.
> Reporter: Urban renewal is concerned with rebuilding the City. . . . This is the best Model Cities Program in the country. Maybe on a national level it should be looked at.
> Rex: When are you going to do it?

> (XI) During a Regional Bureau staff meeting several topics had been discussed. Then, Rex said he had two series he wanted done. One involved a five-part series on urban renewal. He said that [City] could be used as case-in-point and he expected American News to pick up the stories and carry them as well. He assigned various reporters to the five parts. (The discussion of the second series then commenced in a similar form, not shown here.)

In (X), the reporter begins by treating the State's rejection of a renewal project as a singular event. Rex then reframes the event: treat "this case" as part of a broad public issue ("I'm concerned with the whole philosophy of urban renewal. . . ."). The reporter offers an alternative account: City redevelopment is sound, but it may be a problem on a national level. Since the Editor did not deny the newsworthy character of the rejection of the City project, the alternative accounts were allowed to pass at this point. However, in (XI), Rex presents an elaboration of his previous event and story framing: City urban renewal typifies a national problem. He suggested a series with five major aspects to be covered. Formulating a series is a particular interpretive method by which otherwise discrete events (which could be reported as such) are transformed into a gestalt.[11] However, this particular account of newsworthiness is no more a literal or objective interpretation of "what's really happening" than other substantive organizing principles. In this case, (XI) for example, the American News Editor attended to the stories as isolated news reports *about* City rather than the City program as "a typical case." Consequently, the stories remained on the local pages of the paper's local edition.

Finally, generating newsworthiness often consists of retrospective interpretations of how an occurrence or written depiction was managed "after all" by reporters, editors, copyreaders, and other technical staff. What was "finally" done with a story is used as an interpretive scheme by newsworkers to identify their own competence, treatment of their work by other staff, etc. Here is one kind of example.

> (XII) A reporter had written a story about a program sponsored by the federal government in which people are trained to be bus drivers and bus boys, etc. His original lead to the story criticized the effects of the program—for example, so few got permanent jobs. The American News Editor (who selected the local story for national distribution) added a paragraph early in the story to the effect that there were "good things" about the program too. The reporter said that the American News Editor had misused his discretion by adding a paragraph "without the facts."

SUMMARY

This paper applied principal tenets of ethnomethodology to extend sociological understanding of a crucial part of the news process—that is, how occurrences become newsworthy events and stories. The ethnomethodological perspective is an alternative to the more structural explanations of the news process, especially as found in gatekeeping studies. Various facets of the news process are dependent on newsworker interaction to construct and interpret news criteria and the occurrences such criteria help to render.

---

[11] Framing series is not unique to *The Interpreter*. There is an analogue to this interpretive strategy. Fishman (1978) has done a thorough empirical study of crime waves as the news media's structuring of otherwise discrete occurrences. Here, media personnel not only treat particular occurrences as instances of a news theme, but proffering a theme is a scheme of interpretation for actively searching for instances—that is, occurrences as public events. The structuring and use of news themes is also discussed at length by Halloran et al. (1970), the Glasgow University News Group (1972), Cohen (1972) and Cohen and Young (1973).

Importance and interest are not endemic properties of occurrences, events, or even completed stories. The rules governing newswork are not simply given and available, but actually constructed, interpreted, and elaborated upon in the actual settings of newswork. Reflexively, through the process of generating newsworthiness, occurrences and events are framed in terms of their constituent features, meanings, and consequences. As well, accounts of newsworthiness render newsworkers' own work routines as rational, sensible, and competent. Finally, it has been shown that generating newsworthiness has a direct bearing on what appears or fails to appear in the newspaper.

COMMENTS

THE RELAY ASSEMBLY TEST ROOM: AN ALTERNATIVE STATISTICAL INTERPRETATION*

(Comment on Franke and Kaul, *ASR*, October, 1978)

INTRODUCTION

In what they call the "first statistical interpretation" of the data from the first Relay experiment (the most prolonged of the Hawthorne experiments), Franke and Kaul (1978:623–43) show that well over 90% of the variation in the average productivity of the workers involved can be accounted for by just three explanatory variables: two dummies of their own construction, which they interpret as "managerial discipline" and "economic depression"; and one experimental variable, scheduled rest time. They conclude (pp. 636–7) that "the lack of substantial unexplained variance . . . indicates that the unmeasured supervisory and social interaction variables were not very important economically."

In what follows, I shall show that this conclusion is not supported by the data. Specifically, I shall show that the data agree very much better with models in which average productivity increases gradually, with time, over the first three years of the experiment than they do with the model presented by Franke and Kaul (1978) in which most of the improvement over the first three years occurs in two abrupt jumps. Whether the gradual increase in productivity with time is to be attributed to "unmeasured supervisory and social interaction variables" or to unmeasured variables of some other sort is a question of interpretation on which statistical analysis has nothing to say.

ERRORS IN THE FIRST STATISTICAL ANALYSIS

Franke and Kaul (1978) investigated the output of the workers in the first Relay experiment by their analysis of two families of additive models: Model 1, in which the dependent variable is output per hour, and Model 2, in which the dependent variable is output per week, with hours per week as an additional explanatory variable. Since a reasonable additive model of output per week would have to contain a number of "interaction" terms[1] not included in their Model 2, I shall reexamine only the simpler Model 1.

All results will be based on the data used by Franke and Kaul (1978:639–40) and published in their Appendices; the reader is reminded that the outputs in these data are averages of weekly outputs within each of 23 experimental "periods" varying in length from 2 to 31 weeks. For brevity, the "first Relay experiment" will usually be called simply "the experiment"; "scheduled rest time" will be called simply "rest time"; "productivity" will be used as a synonym for "output per hour." The reader is assumed to be familiar with the discussion by Franke and Kaul, but it may be useful to recall the definitions of the two dummy variables which play so large a part in their explanation of the phenomena. "Managerial discipline" has the value 0 up to the moment when workers 1A and 2A were replaced by workers 1 and 2, the value 1 thereafter. "Depression" has, in principle, the value 0 up to the stock-market crash on October 24, 1929, the value 1 thereafter; it is set to .74 in the period within which the crash occurred. For a reason which will appear in due course, this variable will hereafter be called "crash" rather than "depression."

Serial correlation and the "passage of time." Taking the average productivity of the workers in the experiment as the dependent variable, the stepwise regression program used by Franke and Kaul selected the explanatory variables and produced the regression coefficients and value of R^2 shown in column 1 of Table 1, together with the value 1.58 for the Durbin-Watson statistic. Observing that 1.58 is significant at the .05 level, Franke and Kaul (1978:631) inferred that "passage of time and unspecified historical factors appear to have influenced the residuals," and proceeded to make a partial correction for serial correlation which yielded the coefficients and R^2 in column 2.

Because a continuing increase of productivity over time which cannot be attributed to

---

[1] For example, consider the effect of managerial discipline in a model in which the dependent variable is weekly output. If discipline affects output in each hour worked, then the effect of discipline on weekly output will be not a constant, but proportional to the number of hours worked; and, therefore, the model must contain an interaction variable which is the product of the variables, discipline and hours worked.

any measured explanatory variables is the only way in which the effects of unmeasured variables could manifest their presence in the data available to Franke and Kaul (1978), one might have expected them to investigate the effect of the passage of time a little more fully.[2] It may be, however, that the R^2 they obtained after partial correction for serial correlation was still so large that it simply reinforced their belief that the effect of time was unimportant—if, in fact, it existed at all.

Franke and Kaul's (1978) discussion of the effect of time rests, however, on a misunderstanding of the theory underlying the kind of correction for serial correlation that they applied. Such a correction is not appropriate when the "errors" or "disturbances" (u in the successive values of the dependent variable) are correlated with time. It is appropriate when the errors are *not* correlated with time (or any other potential predictor variable) but are correlated with each other because they are generated by a process such that

$$u_t = \rho u_{t-1} + \epsilon_t,$$

where the ϵ's are assumed to be independent and ρ is a parameter to be estimated just as the coefficients of the explanatory variables are to be estimated.[3]

Serial correlation is, thus, only very indirectly relevant to the real problem at hand, but, for future reference, it is worth remarking that if Franke and Kaul (1978) had analyzed the autocorrelated-errors model by least squares, and if they had then correctly computed the fraction of the variance of average productivity that was explained by the model, they would have obtained the results in column 3 of Table 1.[4] As one would expect, the value of R^2 goes up rather than down when the additional parameter ρ is added to the model, but the important thing to observe is that the changes in the regression coefficients resulting from full allowance for autocorrelation are completely negligible.

Analysis of residuals. Because Franke and Kaul (1978) thought that the residuals may have been "influenced by the passage of time" but really did nothing to determine whether or not they were in fact so influenced, the question remains open. The usual first step in the investigation of a question of this sort is simply to plot the residuals against time; and this is done in Figure 1 for the residuals of the Franke and Kaul model as originally fitted to the data, without any correction for serial correlation. Time is measured in weeks from the start of the experiment; each residual is plotted at the temporal midpoint of the experimental period to which it belongs. The two dashed vertical lines in the figure divide time into three intervals delimited by the imposition of managerial discipline at $t = 39$ (end of period 7) and the crash at $t = 131$ (shortly after the beginning of period 15).

What immediately strikes one on inspecting the plot in Figure 1 is not that the residuals are serially correlated but that they are strongly correlated with time within each of the three intervals which correspond to the "treads" or "flats" in the step function defined by the dummy variables, "discipline" and "crash." The three sloping lines in the figure represent the within-interval regressions of the residuals on time; the fractions of the within-interval variances of the residuals that are explained by the regressions are .538, .264, and .271.[5]

Explicit allowance for passage of time. Given so clear a set of relations between the residuals and time, the natural next step is to look to see what happens if a similar set of relations between productivity and time is allowed to appear explicitly in the explanatory model. If time t is measured in weeks from the start of the experiment, this can be done by introducing three new explanatory variables:

$$\begin{aligned} T1 &= \min\{t, 39\}, \\ T2 &= \max\{0, \min\{t,131\}-39\}, \\ T3 &= \max\{0, t-131\}. \end{aligned}$$

Taken together, these variables allow the effect of time on productivity to appear as a

---

[2] Had Franke and Kaul (1978) added either a measure of time or the serial number of the experimental period to the explanatory variables from which they asked their stepwise regression program to choose, the program would have chosen that variable in lieu of crash. Had they added a variable equal to time up to the crash and constant thereafter, this variable would have been the first variable chosen by their program and would, by itself, have explained 89.2% of the variance of average productivity.

[3] Franke and Kaul (1978:628) cite two papers by Durbin and Watson (1950; 1951) as references for their assertion that the "influence of other (generalized) historical factors as well as the passage of time can be measured as serial correlation," but I can find no trace of such a notion in these papers.

[4] Franke and Kaul took account of serial correlation by use of the approximate transformation called T2 by Johnston (1972:261) instead of the exact transformation T1; and instead of finding the least-squares estimate of p, which is .168, they used the guessed value .25. Their R^2 is the explained fraction of the variance, not of the dependent variable y, but of $(y_t - .25y_{t-1})$.

[5] In contrast, only .030 of the variance of the residuals is explained by the serial correlation which produced the value 1.58 of the Durbin-Watson (1950; 1951) statistic.

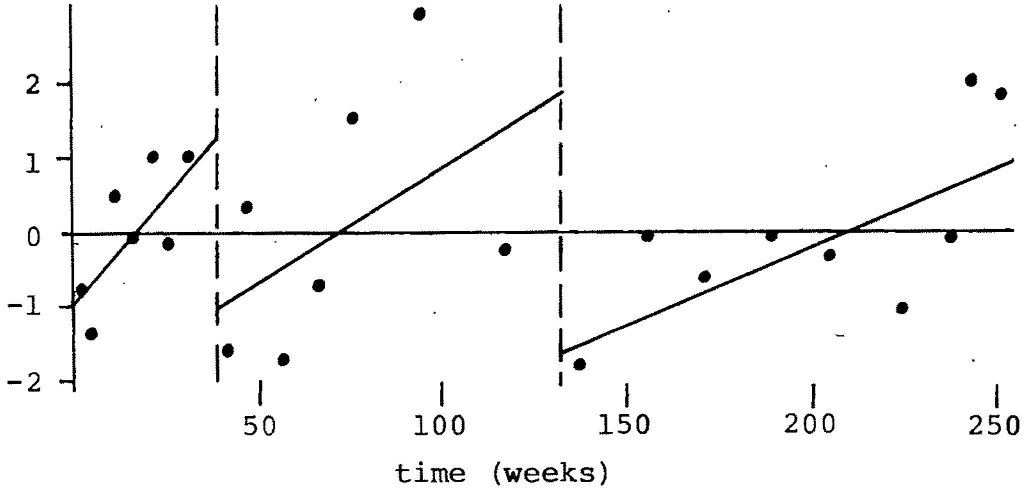

Figure 1. Residuals of Franke and Kaul Model

piecewise-linear continuous function with changes of slope at t = 39 and t = 131. The slope of each linear segment is equal to the regression coefficient of the corresponding T.

Regression of average productivity on these new variables together with the three original Franke and Kaul variables yields the coefficients and R^2 shown in column 4 of Table 1. Notice that, as suggested by Figure 1, the coefficient of T2 is less than that of T1 and the coefficient of T3 is less than that of T2. Productivity seems to increase with time—but at a decreasing rate.

Importance of explanatory variables and decomposition of R^2. Since the R^2 of the augmented model described in column 4 of Table 1 is only .012 greater than that of the original model described in column 1, Franke and Kaul would presumably argue that their conclusion has been confirmed. The effects of T1, T2, and T3 are so small that they are "not very important economically."

Table 1. All Workers; All Periods

	(1)	(2)	(3)	(4)	(5)
Discipline	8.64	8.26	8.50	5.64	5.60
Crash	6.18	6.34	6.27	3.07	.75
Rest time	.176	.164	.176	.113	.127
T1	—	—	—	.121	.103
T2	—	—	—	.026	.046
T3	—	—	—	.023	.029
R^2	.971	.945	.972	.983	.964

(1) Franke and Kaul (1978) Model 1.

(2) Attempted correction for serial correlation.

(3) Serial correlation estimated by least squares.

(4) Piecewise-linear trend added: changes in slope after discipline and crash.

(5) Observations weighted by lengths of periods.

It is interesting, however, to see what would have happened if the six variables in the augmented model had been selected—and their contributions to R^2 computed—by the stepwise regression program used by Franke and Kaul (1978). The variables would have been selected in the order T2, T1, T3, "crash," "rest time," and "discipline"; and the corresponding stepwise increments in R^2 would have been .788, .151, .020, .010, .009, and .005. The sum of the contributions of the three T's would, thus, have been .959; and, therefore, the kind of argument advanced by Franke and Kaul would have led to the conclusion that, because 95.9% of the variance of productivity can be explained by the passage of time, the three explanatory variables in the Franke and Kaul model were not very important economically.

The argument is fallacious, however, in either its revised or its original form. It is only when the explanatory variables are uncorrelated that R^2 or the variance of the dependent variable can be uniquely and, therefore, meaningfully decomposed into a sum of parts due to the several explanatory variables. When the explanatory variables are correlated ("multicollinear"), some quite different way of assessing relative importance must be found if relative importance is to be assessed at all. For example, one might compute that, in the model currently under discussion, passage of time over the 253 weeks of the experiment is responsible for 9.9 units/hour of additional productivity, discipline and the crash for 8.7 units/hour, and 25 minutes of scheduled rest time for 2.8 units/hour.

Heteroscedasticity; weighting of observations. One more assumption implicit in Franke and Kaul's (1978) analysis must be reexamined before trying to get a better understanding of the phenomena by means of least-squares regression. As is well known, fitting by (ordinary) least squares is not justified unless the variances of the random errors in the successive values of the dependent variable can be assumed to be at least roughly equal, but it is easy to see that the variances of the errors in the productivities analyzed by Franke and Kaul cannot all be of even the same order of magnitude.

If we had available the average productivity of the workers in each individual week of the experiment, the natural assumption would be that the variance of the unobservable errors in these weekly productivities was constant from week to week; and the fact that this assumption is, at least, a rough approximation to the truth is borne out by Whitehead's (1938) graph H42 of weekly average productivity. Then, because the productivities which are in fact available for analysis are averages of weekly productivities over periods varying in length from 2 to 31 weeks, it would require some very peculiar assumptions to avoid the conclusion that the variances of the errors in the available data range from about ½ to about 1/31 of the roughly constant variance of the weekly errors.

Unless proper account is taken of this extreme heteroscedasticity, estimates of regression coefficients will be subject to extremely large sampling errors; but, fortunately, it is easy to take the required account. All that is needed is to weight the squares and cross-products for each period by the number of weeks in the period, and this will be done in all regressions to be discussed from now on.[6] Coefficients derived by weighted regression for the six-variable model of Table 1 are shown in column 5 of that table, where one should notice particularly the effect of weighting on the coefficient of "crash" and the relative magnitudes of the coefficients of the T's. The weighted R^2 of the six-variable model is .964, as shown in Table 1; the weighted R^2 of the original Franke and Kaul (1978) model is .940.[7]

Serial correlation reexamined. That the weekly errors were not strictly independent is obvious from several of Whitehead's charts, and it follows that if the weekly data were available one would be obliged to investigate the error structure. The fact that the productivities actually available for analysis are averages over widely varying numbers of weeks means, however, that the model implicit in Franke and Kaul's (1978) correction for autocorrelated errors makes no sense in the present context. One cannot reasonably assume, for example, that the fraction of the mean of 31 weekly errors that is "due to" the mean of 4 preceding weekly errors is the same as the fraction of the mean of 2 weekly errors that is due to the mean of 4 preceding weekly errors. The same objection holds *mutatis mutandis* for any of the more complicated standard time-series error models, and, consequently, all that one can do is regret the fact that it is not possible to take proper account of interdependence of errors. One may, however, take some consolation from the facts that (1) coefficient estimates are unbiased even when no account is taken of autocorrelation of errors, and (2) correction for moderate amounts of autocorrelation often results in negligible changes in regression coeffficients, as is illustrated by the close agreement between columns 1 and 3 of Table 1.

DISCIPLINE AND DEPRESSION

Managerial discipline. As Franke and Kaul (1978:631) themselves recognize, the variable they call managerial discipline is a rather peculiar mixture which "includes better-performing replacement workers as well as the disciplinary example" resulting from the replacement of workers 1A and 2A at the end of period 7. The Hawthorne experiments were directed, however, not to the effects of what is ordinarily called personnel selection but to the factors affecting the productivity of a given worker or group of workers. What is needed for evaluation of these factors is an estimate of the effect of the "disciplinary example" on the average productivity of the workers who were *not* replaced at the end of period 7, namely workers 3, 4, and 5.

Even though worker 5 was temporarily replaced at the end of period 13, for a reason having nothing to do with discipline, we still have data available for the purpose at hand for workers 3, 4, and 5 from the start of the experiment, 39 weeks before discipline was exercised, to the end of period 13, 75 weeks after the exercise. Column 1 of Table 2 shows the results of weighted regression of the average productivity of these three workers on four of the six explanatory variables appearing in Table 1, the two omitted variables being irrelevant to the first 13 periods. The only striking difference between the regression coefficients in column 1 of Table 2 and those in column 5 of Table 1 is in the coefficient for managerial discipline, which was 5.60 for all workers (really, workers' "positions" or "slots") but becomes 1.76 for workers 3, 4, and 5 alone. This, of course, is just as one would expect, since the 5.60 includes the effect of the fact that workers 1 and 2 (particularly 2) were clearly faster than 1A and 2A.

---

[6] If the natural model is $y = \beta_0 + \beta_1 x_1 + \ldots + \beta_k x_k + \epsilon$, weighted analysis of the natural model is equivalent to unweighted analysis of the transformed model $y\sqrt{w} = (\beta_0 + \beta_1 x_1 + \ldots + \beta_k x_k)\, y\sqrt{w} + \epsilon^*$, where w is the number of weeks in the experimental period and the ϵ^*'s are assumed to be homoscedastic.

[7] How R^2 should be computed for a weighted regression—or, better, *what* R^2 should be computed—is a question without a unique answer. One may define R^2 to be the explained fraction of the variance of either $y\sqrt{w}$ (see previous note) or y; and in the latter case, one may compute the explained fraction of either the unweighted variance of y or the variance obtained when each y is weighted by the number of weeks it represents. The values of R^2 quoted in the present paper correspond to the last-named alternative.

If, however, one now examines the data on the productivities of workers 3, 4, and 5 in Franke and Kaul's (1978) Appendix 2—or, better, if one examines the graph of their weekly productivities in Roethlisberger and Dickson (1939:76)—it is hard to see any evidence of an abrupt increase in productivity at the end of period 7 which was maintained, unchanged, forever after. Rather, what one sees is an increase in period 8, when hours per day were reduced from 8¾ to 8¼; another increase in period 9, when hours were further reduced to 7¾; followed by a decrease in period 10, when hours were put back to 8¾. Inclusion of hours per day among the explanatory variables yields the regression coefficients in column 2 of Table 2, where R^2 has increased from .977 to .993 while the apparent effect of discipline has been reduced from 1.76 to .37 units/hour, or less than .7% of the average productivity of the concerned workers at the time the discipline was applied.

This result is not at all surprising. Workers 1A and 2A were not fired or punished in any ordinary sense of the word. They were merely taken out of the experiment and put back to work under ordinary conditions in "the department." What is more, they were not taken out of the experiment "because of their unsatisfactory attitudes in response to requests for greater diligence and more output," as asserted by Franke and Kaul (1978:627). They were removed because of behavior which risked disrupting the entire experiment, as evidenced by the fact that workers 3 and 4 refused to talk to them in period 7, and by the fact that both worker 4 and an auxiliary worker (called the "layout operator") "began to ask that either they or operators 1A and 2A be removed from the test room" (Roethlisberger and Dickson:55,169; Whitehead:117–9).

Table 2. Workers 3, 4, 5; Periods 1–13

	(1)	(2)	(3)
Discipline	1.76	.37	—
Rest time	.127	.114	.110
T1	.121	.134	.144
T2	.078	.102	.106
Hours/day	—	−3.33	−3.54
R^2	.977	.993	.993

One might well argue that the estimated effect of managerial discipline on workers 3, 4, and 5 is nothing but sampling error,[8] and, in any case, it is so small that elimination of discipline as an explanatory variable scarcely affects the coefficients of the other variables and leaves R^2 unchanged to 3 decimal places, as shown in column 3 of Table 2. Because attempts to construct an improved model of the effect of the passage of time would be seriously confused by inclusion in the list of explanatory variables of an adjustable step-function—which, at least for the moment, seems to explain almost nothing at all—discipline will be excluded from this list for the time being. Its effect will, however, be carefully reevaluated before any final conclusions are reached.

Dating of the depression. Column 5 of Table 1 implies that the crash on October 24, 1929, was immediately followed by an increase of .75 units/hour in the average hourly output of all workers, an increase which Franke and Kaul (1978) interpret as the result of job insecurity due to the depression. This result must be reexamined, however, because the crash in the stock market was not immediately and universally recognized as heralding a general economic depression. Exactly when the workers first began to fear loss of their jobs cannot be determined, but the first clear danger signal did not reach them until the start of period 17 on May 5, 1930, when both the length of the workday and the number of worksays per week were permanently cut back for economic—rather than for experimental—reasons.

The data uncontaminated by worker replacements which are available for reexamining the dating of the first effect of the depression consist of the productivities of workers 1, 2, 3, and 4 in periods 8 through 23. These data cover 92 weeks preceding the crash, 27 weeks from the crash to the cutback, and 95 weeks from the cutback to the end of the experiment. Data on worker 5 cannot be used because she was absent in periods 14–16, which include the crash and immediately precede the cutback.

---

[8] The stepwise regression program used by Franke and Kaul (1978) would reach this conclusion, since the (two-tail) P-level of the coefficient of managerial discipline is .144 in column 1 of Table 2 and becomes .634 when hours/day are introduced as an explanatory variable in column 2. The program would on the other hand accept hours/day as an explanatory variable because its two-tail P-level is .006.

The first two columns of Table 3 show the results of weighted regression of the average productivity of workers 1–4 in periods 8–23 on two very similar sets of explanatory variables. Both sets allow a linear trend in productivity up to the shock of the depression, a step at that point, and then another linear trend with altered slope. The only difference between the two sets is in the date of the step and the change in slope, which is October 24, 1979 ($t = 131$) in column 1, and the following May 5 ($t = 158$) in column 2. Formally, the three new variables in Table 3 are defined by

$$\begin{aligned} &T2^* = \max\{0, \min\{t,158\}-39\}, \\ &T3^* = \max\{0, t-158\}, \\ &\text{cutback} = 1 \text{ if } t > 158. \end{aligned}$$

The one noteworthy difference between the coefficients in columns 1 and 2 is in the coefficient of the step, which indicates an increase of .45 units/hour when dated to the crash, a decrease of 1.38 units/hour when dated to the cutback.

The difference between the .893 value of R^2 obtained with the step at the cutback and the .886 obtained with the step at the crash is much too small, by itself, to carry any weight—but there is very strong nonstatistical evidence pointing in the same direction. That the first effect of the depression should be dated to the cutback rather than to the crash is supported by the fact that no worker is reported by Whitehead (1938:148–9) as mentioning possible layoffs until immediately after the cutback. That the depression did not have a positive effect on productivity is supported by the fact that in all the subsequent conversations concerning layoffs reported by Whitehead (1938:149–51, 168–70, 178–85), there is no trace of belief by any worker that her job could be protected by increased output. That job insecurity actually had a negative effect on productivity is supported by evidence from outside the first Relay experiment. In the Mica experiment, the serious job insecurity which began to be felt in August of 1929, for a reason unconnected with the depression, was accompanied by a decrease in productivity, not by an increase (Roethlisberger and Dickson:153, 147).

Table 3. Workers 1, 2, 3, 4; Periods 8–23

	(1)	(2)	(3)
Rest time	.152	.149	.149
Hours/day	−.76	−1.02	−1.02
T2	.071	—	—
Crash	.45	—	—
T3	.005	—	—
T2*	—	.070	.070
Cutback	—	−1.38	−1.18
T3*	—	.004	—
R^2	.886	.893	.893

For all these reasons, the shock of the depression will be assumed in what follows to have really "hit" the workers in the Relay experiment with the cutback on May 5, 1930, at the start of period 17.

Changes in productivity after the cutback. The coefficient of T3* in column 2 of Table 3 implies that immediately after an abrupt drop due to the cutback, productivity increased very slowly—but continuously—up to the end of the experiment, 95 weeks later. It is impossible, however, to see evidence of such a trend in the data as presented either in Franke and Kaul's (1978) Appendices or in Whitehead's (1938) chart, H42. What inspection of the data does suggest is virtually constant productivity over the first 83 weeks (periods 17–21), followed by a sudden increase in the last 12 weeks (periods 22 and 23); and this visual impression is confirmed by the fact that regression of the average productivity of all workers on time during the first 83 weeks after the cutback yields a negative—rather than a positive—coefficient, −.009.

Although such a downtrend agrees with what was said earlier about the probable nature of the effect of the depression, its inclusion in the model would require the presence of not only the variable T3* but also a dummy with value 1 in periods 22 and 23 to prevent the downtrend from being converted into an uptrend. Since no causal interpretation of such a dummy has been offered, and since the total effect of the apparent downtrend amounts to only .009×83 = .75 units/hour over the entire 83 weeks that it may have persisted, the wiser course seems to be simply to drop the variable T3* from the model and leave all variation in productivity after the cutback "unexplained."

The effect of dropping T3* is shown in column 3 of Table 3, where there is a slight change in the coefficient of cutback but R^2 remains unchanged to 3 decimal places. The effect on the coefficients of the other variables is necessarily zero, since the presence in the model of the step-variable cutback, with a jump between periods 16 and 17, means that the coefficient of any variable other than cutback whose value is constant in periods 17–23 depends on neither the data for these periods nor the presence in the model of any variable other than cutback whose value is constant in periods 1–16.

MODELS FOR THE ENTIRE EXPERIMENT

Now that data on subsets of workers and periods have been used to decide some critical modeling questions, it is time to "put it all back together" by trying to explain the changing average productivity of all workers over the entire duration of the experiment. What makes the task "tricky" is the need to avoid confusing the changing productivity of workers with the effects of substitution of one worker for another.

Elimination of replacement effects. The only data covering the entire duration of the experiment that come to us uncontaminated by the effects of worker replacements are those for workers 3 and 4. Weighted regression of the average productivity of these two workers on the explanatory variables chosen for reasons already set forth yields the results in column 1 of Table 4.

To bring worker 5 into the analysis, one must replace the productivities of her very inferior substitute, 5A, in periods 14–16, by values which will let the contributions of these periods to the analysis depend on only the productivities of workers 1–4. Such values can be found by, first, regressing worker 5's productivity on the productivities of workers 1–4 in periods 8–13 and 17–23 and, then, computing regression "estimates" of the productivities of worker 5 in periods 14–16. The estimates thus computed are 58.8, 62.0, and 64.4; and, after the series for worker 5 has been patched with these values, regression analysis of the average productivity of workers 3, 4, and 5 over all periods yields the results in column 2 of Table 4.[9]

Finally, the data on workers 1A and 2A can be spliced with the data on 1 and 2 by multiplying the productivity of the former pair by a factor representing the inherent superiority of the latter pair.[10] The required factor can be estimated by, first, computing (1) the ratio of the total output of workers 1A and 2A to the total output of workers 3–5 in periods 1–7 and (2) the ratio of the total output of workers 1 and 2 to the total output of workers 3–5 in periods 8–23, and, then, dividing the results of (2) by those of (1). That result is 1.133; and, after the average productivity of workers 1A and 2A in each of the first 7 periods has been multiplied by this factor, regression analysis of the average productivity of all workers over all periods yields the results in column 3 of Table 4.

Table 4. All Periods; No Replacement Effects

	(1)	(2)	(3)
Hours/day	−1.92	−2.75	−2.45
Rest time	.106	.090	.108
T1	.234	.189	.167
T2*	.073	.074	.079
Cutback	−3.20	−3.08	−2.39
R^2	.915	.952	.972

(1) Workers 3,4; natural data.
(2) Workers 3,4,5; data for 5 adjusted.
(3) All but 5A; data for 1A, 2A, and 5 adjusted.

A smooth model of the effect of passage of time. Since replacement of workers 1A and 2A at the end of period 7 has been shown to have had little—if any—effect on the productivity of the other workers, there is no longer any justification for representing the effect of the passage of time over periods 1–16 as a piecewise-linear function with an abrupt change of slope at the end of period 7. The effect is more naturally represented as a smooth function which increases at a decreasing rate from the start of the experiment up to the first shock of the depression, at $t = 158$, and then remains constant to the end of the experiment, at $t = 253$. In order both to minimize the number of adjustable parameters in the model and to make a smooth transition between positive growth of productivity with time up to $t = 158$ and zero growth thereafter, the effect of time will be assumed to be proportional to a quadratic variable Q1 whose derivative with respect to time decreases gradually to 0 at $t = 158$ and remains 0 thereafter. Formally, this new variable is defined by

$$Q1 = x - x^2/316 \quad \text{where} \quad x = \min\{t, 158\}.$$

When Q1 is substituted for the T1 and T2* of Table 4, weighted analysis of the adjusted average productivity of all workers except 5A

---

[9] A case can be made for patching the series for worker 5 with estimates based on the regression of her productivity on the total productivity of workers 1–4 rather than their individual productivities, but the choice is unimportant because the estimates derived by this alternative procedure (59.4, 62.3 and 65.3) would lead to results equivalent for all practical purposes to those obtained using the estimates quoted in the text.

[10] The nonexistent productivities of workers 1 and 2 in periods 1 to 7 could of course be dummied-up by the same device used for worker 5 in periods 14 to 16. The reason for not so doing is simply that there is some hope of extracting some useful information from the actual performance of workers 1A and 2A in a crucial part of the experiment, whereas there seemed to be no hope of extracting anything useful from the actual performance of worker 5A in periods 14 to 16.

Table 5. All Workers Except 5A; Adjusted Data

	(1)	(2)	(3)	(4)
Hours/day	−2.72	−2.89	−2.82	−2.74
Rest time	.119	.137	.128	.130
Incentive	—	—	1.27	1.05
Defectv rm	—	—	—	−.77
Q1	.178	—	—	—
Q4	—	.167	.165	.173
Cutback	−.63	−.88	−.78	−1.16
R^2	.972	.972	.974	.975

yields the coefficients shown in column 1 of Table 5.[11] R^2 is as great for the new model as for the old even though the number of adjustable parameters has been reduced by one.

Incentive compensation. An improved, small-group wage incentive was introduced at the start of period 3, but, in trying to evaluate this change, the experimenters feared that its effect—if any—might be confused with "Hawthorne effect"; and, therefore, even before the first Relay experiment was concluded they conducted a brief, second Relay experiment in order to get independent evidence. The evidence thus obtained was hard to evaluate for a number of reasons (Roethlisberger and Dickson: chap. 6), but, such as it was, it "tended to substantiate the hypothesis that [the incentive] was an important factor" in productivity in the first Relay experiment (P. 133),[12] and it also gave some reason to think that the effect of the incentive was immediate (that is, abrupt) rather than gradual (p. 159).

If—contrary to this very weak evidence—the incentive *did* have any gradual effect, this effect must remain a statistically unidentifiable part of the whole set of effects of unmeasured variables which, together, make up the "effect of the passage of time." It is quite conceivable, for example, that the incentive acted as a multiplier of the effects of other, unmeasured variables.

The immediate effect of the incentive, on the other hand, may possibly be captured by Franke and Kaul's dummy variable which has the value 1 starting in period 3, but not if this variable is included in a model which also allows for a continuing increase of productivity with time, starting at $t = 0$. In such a model, the value and even the sign of the coefficient of incentive are extremely sensitive to very slight changes in the representation of the effect of time and to the presence or absence of other explanatory variables.

To avoid, insofar as possible, crediting time—that is, the unmeasured variables—with any part of the immediate effect of incentive, incentive will be introduced into a new model in which productivity is assumed not to increase with time at all until the start of period 4 at $t = 15$. The model is constructed by substituting for the variable Q1 a new variable Q4 defined by

$$Q4 = z - z^2/286 \quad \text{where} \quad z = \max\{0, \min\{t,158\}-15\}.$$

Lke the derivative of Q1, the derivative of Q4 with respect to time decreases smoothly to 0 at $t = 158$ and remains 0 thereafter.

Substitution of Q4 for Q1 without adding incentive to the model yields the results shown in column 2 of Table 5, where it should be observed that the coefficients are not very different from those based on Q1 in column 1 while R^2 is unchanged to 3 decimal places. Addition of incentive to this model then yields the results in column 3. The apparent immediate effect of the incentive is an increase in productivity of 1.27 units/hour.[13]

Defective raw materials. In periods 14 and 15, an unusually large number of defective component parts (called "raw materials" by Franke and Kaul [1978]) seem to have been supplied to the workers, and the Franke and Kaul data include a dummy variable which has the value 1 in these two periods. That this variable may have had some effect on productivity is indicated by the fact, pointed out by Franke and Kaul in their Model 3, that it is closely related to the amount of time the workers had to spend in repairing defective relays. Weighted regression of repair time on this variable alone explains 76% of the variance of repair time and indicates nearly 22 minutes per day of extra repair time during the affected periods.

---

[11] Strictly speaking, this analysis assumes that average productivity in any period is proportional to the value of Q1 at the midpoint of the period, not to the average value of Q1 in the period. Since any model of the effect of time that can be invented will be at best only a rough approximation to the truth, averaging would be a meaningless refinement.

[12] Franke and Kaul (1978:636) cite no source for their assertion that it was "contrary to the views of the Hawthorne researchers" that the incentive had a "positive influence" on productivity.

[13] A naive estimate of the immediate effect of the incentive may quite possibly be better than one based on a model involving other explanatory variables. By simply subtracting productivity in period 2 from productivity in period 3 one gets 51.0 − 49.1 = 1.9 units/hour or 3.9% as the immediate increase due to the incentive. No method of estimation has been found which yields anything like the 12.6% increase which immediately followed the introduction of the incentive in the second Relay experiment (Roethlisberger and Dickson, 1939:132), and this may well have been one of the reasons why Roethlisberger and Dickson concluded (pp. 133–4, 158, 577) that the 12.6% increase was in part a result of factors other than the incentive. Carey (1967:409), who violently attacks Roethlisberger and Dickson for this conclusion, gives no hint at his own explanation of the apparently much smaller immediate effect of the incentive in the first Relay experiment.

Addition of "defective raw materials" to the explanatory variables evaluated in column 3 of Table 5 yields the results in column 4. The indicated effect of the defective parts is a reduction in productivity of .77 units/hour, substantially less than implied by the 22 minutes per day of extra repair time.

Days per week. One more explanatory variable in the Franke and Kaul (1978) data, days/week, would seem promising but will remain unused. This variable enters virtually any model of the entire experiment with the wrong sign +, essentially because of the inexplicably low productivity in period 14, when days/week were experimentally reduced from 5-½ to 5. Separate analysis of the data from periods 17 to 23 only, where most of the variation in days/week took place, indicates a negligible increase of .33 units/hour for a reduction of half a day.

Rest Time. For a reason of the same kind as the one which prevents proper evaluation od days/week in a model of the entire experiment, the one which prevents proper evaluation of fect of rest time is, in fact, not so well founded as it seems. It depends too heavily on the low productivity in the single period 12 when rest stops were temporarily eliminated. If this one period is eliminated from the data, the coefficient .110 in column 3 of Table 2 is reduced to .044, the coefficient .130 in column 4 of Table 5 is reduced to .077, and so forth. In other words, elimination of rest stops seems to have reduced productivity much more than their introduction increased it.

IMPORTANCE OF THE PASSAGE OF TIME

Implications of the quadratic model. Since the model evaluated in column 4 of Table 5 includes all variables which seem to have had any material influence on productivity, it can be used as a basis for a rough evaluation of the importance of the passage of time relative to the experimental variables under managerial control, namely hours/day, rest time, and incentive. For comparison with other models to be introduced later, the description of this quadratic model is reproduced in column 1 of Table 6, where the numbers in parentheses will be discussed later on.

Statistically, time is by far the most important explanatory variable in the quadratic model, judging by the only method of evaluation that makes sense when the explanatory variables are highly correlated. Elimination of Q4 from the model reduces R^2 from .975 to .763, whereas elimination of the variable which is next most important in this sense—rest time—reduces R^2 only to .950.

And, what is even more relevant, Q4 is by far the most important variable economically. Its coefficient .173 implies that over the 143 weeks from the start of period 4 at t = 15 to the cutback at t = 158, passage of time was responsible for a total increase in productivity of $.173\times(143/2) = 12.4$ units/hour. This is to be compared with the 1.05 units/hour attributed by the model to incentive, 2.74 units/hour attributed to a reduction of one hour in the length of the workday, and $.130\times25 = 3.25$ units/hour attributed to 25 minutes of scheduled rest time, all of which taken together add up to less than 7.1 units/hour—or to less than 57% of the effect of the passage of time.

Alternative models. To test the sensitivity of these results to the choice of the variable Q4 in modeling the effect of time, two alternative models are described in columns 2 and 3 of Table 6. In column 2, the effect of time is assumed proportional to the square root of t-15 from t = 15 to t = 158 and constant thereafter. In column 3, it is assumed linear in t-15 from t = 15 to t = 158 and constant thereafter. Two facts are to be observed:

(1) In regard to the total effect on productivity of the passage of time, the square-root and linear models imply a growth from t = 15 to t = 158 of 15.1 and 15.6 units/hour, respectively—or substantially more than is implied by the quadratic model.

(2) The linear model attributes considerably more importance to the effects of the other variables than is attributed by the quadratic model, but the total effect attributed by even the linear model to incentive, a one-hour reduction in the workday, and 25 minutes of rest time is only 8.6 units/hour, or 55% of the 15.6 units/hour it attributes to the passage of time.

Statistical significance. Since explanatory variables have not been admitted to any model unless they entered with a prespecified sign, one-tail tests of significance are presumably called for, and, therefore, one-tail P-levels are shown in parentheses in Table 6. Two remarks seem called for:

(1) In the linear model described in column 3, the coefficients of all variables except incentive are significant at the .01 level, and the coefficient of incentive is almost significant at

Table 6.

R^2	.975	.971	.983	.984

(1–3) All workers except 5A; adjusted data.
(4) All workers; unadjusted data.

the .05 level. I would argue, nevertheless, that this model is to be rejected out of hand because of the large value (−5.72) of the coefficient of cutback. Inspection of the data makes it obvious that productivity did not, in fact, drop by anything like this amount at the end of period 16. What is really certain is that by the end of period 16 the linear trend has seriously overshot the mark.

(2) In the quadratic model of column 1, the coefficients of incentive, defective raw materials, and cutback are nowhere near significant, evan at the .05 level. I would argue that the estimated coefficients of these variables are, nevertheless, the best available indications of what the data have to say; but it should also be noted that, if the offending variables are eliminated from the quadratic model, the implied total effect of time becomes 11.7 units/hour while the total effect of a one-hour reduction in the workday and 25 minutes of rest time becomes only 5.5 units/hour, or 47% of the effect of time.[14]

DISCIPLINE REEXAMINED

Early on, Franke and Kaul's (1978) "managerial discipline" was tentatively rejected as an explanatory variable with a promise that another look would be taken before any final conclusions were reached. As the first of two final checks, the *unadjusted* average productivity of all workers—exactly as it appears in the Franke and Kaul data—was regressed on the explanatory variables of the quadratic model plus "discipline." The results of weighted regression are shown in column 4 of Table 6.[15] The coefficient of "discipline" implies an increase in total output of only 5×1.49 = 7.45 units/hour, or less than the 12 or so units/hour one might have expected, as the direct effect of the replacement of workers 1A and 2A by the more rapid workers 1 and 2.[16] Of an effect of the "disciplinary example" there is no trace.

As a second check on discipline as an explanatory variable, the results of fitting the quadratic model to the unadjusted individual productivities of the workers are shown in Table 7. In columns 1 and 2 of this table, the pairs 1A,1 and 2a,2 are treated as single workers; in column 5, the results are based on the data for periods 1 to 13 and 17 to 23 only, excluding the periods during which worker 5 was absent all (or a large part) of the time. The direct effect of the replacement of workers 1A and 2A would appear to have been an increase of only 5.41 + 3.65 = 9.06 units/hour in total output—again, less than the 12 or so units/hour one might have expected as a result of the inherent superiority of workers 1 and 2. In regard to the other workers, the effect of the "disciplinary example" would appear to have been an increase of 1.86 units/hour in the output of worker 3, and decreases of .99 and 3.07

---

[14] When the three variables are dropped from the model, the coefficients of hours/day, rest time, and Q4 become respectively −.192, .143, and .163. R^2 is .971.

[15] In comparing the coefficients in column 4 with those in column 1, one must remember that in column 4 "defective raw materials" is picking up not only the effect of the defective parts but also the clearly inferior performance of worker 5A in periods 14 and 15.

[16] In discussing "Elimination of Replacement Effects," it was shown that, relative to workers 3–5, the total productivity of workers 1 and 2 was, on the average, 11.3% greater than that of workers 1A and 2A. Multiplying this percentage into the 107.9 units/hour produced by 1A and 2A in period 7 yields 12.19 units/hour as the increase in total units/hour one might have expected as the result of the replacement.

Table 7. Individual Productivities of Workers 1–5

	(1)	(2)	(3)	(4)	(5)
Hours/day	−2.59	−4.84	−1.73	−3.61	−6.20
Rest time	.135	.123	.144	.145	.052
Incentive	.07	−.03	3.42	.30	1.46
Defectv rm	−1.88	−1.08	−2.21	−.36	—
Q4	.177	.275	.106	.254	.187
Cutback	−.49	−2.58	−2.26	−3.73	−2.34
Discipline	5.41	3.65	1.86	−.99	−3.07
R^2	.951	.984	.924	.910	.939

units/hour in the outputs of workers 4 and 5, respectively, adding up to a net *decrease* of 2.18 units/hour.

It would, thus, seem to be established—about as clearly as such things can be—that managerial discipline, as distinct from personnel selection, was not a material factor in the history of the Relay Assembly Test Room. If one asks how a model in which time is replaced by discipline could yield a very high R^2 when fitted to the data, one need not seek far to find the answer. The coefficient of correlation between discipline and the smooth trend variable Q4 is .842. As Franke and Kaul included no smooth function of time among the predictor variables from which they asked their stepwise regression program to choose, the program took discipline as an excellent proxy and produced an excellent example of spurious correlation.

CONCLUSIONS

Despite uncertainty about the exact form of the relation between productivity and time, and despite very great uncertainty about the magnitudes of the effects of some of the other measured variables, there are two qualitative conclusions concerning the first Relay experiment that can be drawn, with considerable certainty, not from the models in Table 6 alone but also from the entire investigation which led to these models:

(1) The data agree very much better with models which include a smooth function of time as an explanatory variable than they do with models which do not. The exact form of the function is not at all critical. All that is required is that the function be capable of representing increase at a rate which becomes nearly (if not quite) zero, some time before the middle of the year 1930.

(2) Economically, the unmeasured variables for which time is a proxy will be, by far, the most important explanatory variables in virtually any model which allows their net effect to manifest itself in the way just described.

These two conclusions are, of course, nothing but restatements (in statistical jargon) of observations made by the original Hawthorne researchers more than 40 years ago. Digital computers and regression programs are not really needed to demonstrate the importance of "the effect of the passage of time," because mere inspection of Whitehead's (1939) chart H42 shows that the uniquely remarkable fact about the first Relay experiment is the almost continuous, "objectively" inexplicable growth of productivity with time over the first three years of the experiment. With the interpretation of this remarkable growth that was offered by the original researchers, other scholars are, of course, free to disagree; but they are not likely to find any plausible way of manipulating the data that allows them to deny its existence or its importance. The data, as such, are in all respects consistent with the conclusions reached by the original researchers.

WORKER PRODUCTIVITY AT HAWTHORNE*

(Reply to Schlaifer)

A remarkable industrial experiment involving workers and managers of a major manufacturing company was begun in April 1927 and was continued until May 1933. The interpretation that increased productivity resulted from improved social relations, presented in influential reports published between 1933 and 1939, has provided a foundation to the present social science of work. Insofar as worker productivity is a matter for concern today,[1] it is more than an exercise in the history of science to reappraise the evidence that led to the early "human relations" conclusions.

The experiment provided for changes in working conditions and for extended close observation of assembly workers in the large plant of the Western Electric Company at Hawthorne Station near Chicago. It began in the regular assembly room to provide base-line data and, during the third week, was moved to the partially isolated "first relay assembly test room." The Western Electric experimenters studied only five direct production workers at a time, but they collected weekly (and daily) records that provide hundreds (thousands) of measures of performance and attitude. Within each of 23 periods that ranged from 2.3 weeks (11.6 workdays) up to 31 weeks (166 workdays), and for a final but disrupted 24th period that lasted 60 weeks, experimental conditions were held as nearly constant as may be possible in a complex field setting. Experimental variables were aspects of physical work environment and work requirements, changes in management and supervision, and changes in social relations of workers. Also occurring were some unintended alterations in working conditions which could be measured or otherwise attributed to certain portions of the six years of the experiment.

In our (cf. Franke and Kaul, 1978:639,640) report two years ago, which was the first systematic statistical analysis of worker productivity in the Hawthorne experiments, we made the period-by-period data from the first relay experiment accessible so that others could carry our work further. It is gratifying that, in addition to the critical comments of Wardwell (1979), an alternative statistical interpretation has now been offered by Robert Schlaifer (1980). Both these reviews have contributed to the present response which contains further and necessarily more detailed analysis. To encourage additional investigations, the weekly experimental data and a guide to records by the actual experimenters are provided here in Appendices 1 and 2.[2]

In his Comment, preceding, Schlaifer (1980) develops a number of models to explain the among-periods variance in hourly output rate of workers in the first relay experiment. He argues that his models, all of which include one or more independent variables that contain functions of time, are improvements in that "the data agree very much better" with them than do the data with the model presented by us. Our (Franke and Kaul, 1978:631, 633) Model 1 sought, instead, to explain group and individual productivity exclusively by measured experimental variables, both advertent and inadvertent. Model 1 uses but 3 variables—managerial discipline, the economic depression, and scheduled rest time, all of which had positive effects—to explain 97.1% of the variance in hourly output among periods. Schlaifer's best models in terms of data agreement (variance explanation) for all

I am grateful for the comments by Ralph Alexander, Gerald Barrett, Arthur Gerstenfeld, Leonard Goodwin, and Leon Graubard and, especially, for the detailed suggestions by Elke Franke and Douglas Woods.

This work has been supported in part by National Science Foundation Grant No. IST-7916483 for the study of the critical review process.

[1] Edward Denison (1979) has noted a lack of growth in U.S. labor productivity since 1973. However, long-term stagnation in capital (or managerial) productivity seems a more basic problem than is the still substantial long-term growth of labor productivity in manufacturing (cf. American Productivity Center, 1980; Franke, 1979a; Nystrom and Franke, 1977). Beyond economics, Albee (1977) and Dooley and Catalano (1980) summarize psychological and social effects of economic decline and other change.

[2] In further research on the Hawthorne experiments, the extensive quantitative and verbal information available in the Western Electric records should be consulted, at least for clarification of such information as has been published. The analyses and interpretations by the actual experimenters in the first relay assembly test room are worthy of study in the original. The microfilm copies of most of these records are deposited at the Hawthorne Plant, University of Wisconsin–Milwaukee, Worcester Polytechnic Institute, and Harvard University. Additional copies for research may be obtained from William Roselle, Director of the Golda Meir Library, University of Wisconsin—Milwaukee. The original records have been on deposit in the Archives of the Baker Library at Harvard since 1977. (Cf. also Franke, 1979b:fn. 3.)

periods are equation (4) in his Table 1 and equation (4) in his Table 6, the latter of which is repeated in his Table 7 for individual workers. His equations (here labeled Model T-1(4) and Model T-6(4)) use 6 and 7 variables to explain 98.3% and 98.4% of the variance in average hourly output rate of the group. Since these models employ the same unadjusted data base as Franke and Kaul's (1978) Model 1, direct comparison is possible.

In addition to attempting to demonstrate that his models are better, Schlaifer (1980) expresses concern with several statistical attributes of our (1978) Model 1:[3]

> (a) possible high interrelationships among independent variables used, or (roughly) *multicollinearity;*
> (b) likely unequal variance of regression equation residuals over periods that differ greatly in length, or *heteroscedasticity;* and
> (c) difficulty of testing for a time pattern in regression residuals that might show lack of serial independence, or *serial correlation (autocorrelation),* given the presumed condition of heteroscedasticity.

The following response asserts to the contrary that our (1978) Model 1 is not much worse in its agreement with the data than are Models T-1(4) and T-6(4) and that, from several points of view, Model 1 is to be preferred. It is relatively parsimonious and conveys simple meanings. The Model 1 elements:

> (a) do not show multicollinearity,
> (b) are supported in circumstances without presumed heteroscedasticity (in calculations that follow), and
> (c) are shown significant after correction for serial correlation.

In fact, Schlaifer's models include composite variables that ultimately confound rather than explain the behavior in the experiment. While in some cases he has dealt indirectly with the issue of heteroscedasticity, his models T-1(4) and T-6(4) are highly multicollinear, further confounding interpretation. They are also serially correlated, so that the tests for significance attempted in his Tables 6 and 7 cannot be performed.

The question as to whether Schlaifer's variables—and, thus, his equations—are meaningful is treated in the Method section where it will be demonstrated that further effort to adjust for technical problems in the alternative models is unwarranted. Means for dealing with multicollinearity, heteroscedasticity, and serial correlation are described prior to applying them in the quantitative analyses of the Results section.

METHOD

Data for More Precise Analysis

Weekly productivity data for individual operators and for the group were obtained from the original Hawthorne records, and these are presented in Appendix 1. The data are also summarized in Table 1, with results for some periods being different from those in Appendices 1 and 2 of Franke and Kaul (1978). The differences are slight (as shown by the .998 correlation between the earlier and the present group means) and probably result from the "estimates" for holidays or absences that had been included in the calculations of the Hawthorne experimenters and, thus, in our earlier periodic data.

Also in Table 1 are slope coefficients from regression of productivity of the group upon time for the weeks in each experimental period. These slopes indicate the extent of within-period rise or decline per week in group productivity. There were 15 periods with rises in productivity and 9 periods with declines. Five of the rises and four of the declines are or appear to be statistically significant. In order to summarize the productivity data both among and within periods, the regression lines of productivity against time are plotted for each period in Figure 1. Those lines that appear significantly different from horizontal are heavily shaded. Figure 1 illuminates those "within-period changes . . totally obscured by a statistical technique based on mean outputs for each period" (Wardwell, 1979:860), as do the statistical analyses of the weekly data for all periods (see Results section, herein). Examination of Figure 1 also allows initial evaluation of Schlaifer's (1980) statements that there was "gradual increase in productivity with time," . . . "an almost continuous, 'objectively' inexplicable growth of productivity with time over the first three years of the experiment." For the moment, it is left to the reader to determine from Figure 1 whether changes in productivity were gradual or sometimes abrupt and whether growth almost continuously occurred, or was interspersed with decline, from period 1 to period 16 (over the first 3 years).

Development of Composite Variables for Alternative Models

In constructing alternative statistical models, Schlaifer analyzed the residuals from

---

[3] Model 1 (Franke and Kaul, 1978) showed possible serial correlation, as measured by the Durbin and Watson (1951) coefficient and their Table 4. The model is presented in original and variously corrected forms in Schlaifer's. Table 1, columns (1) through (3).

24[f]	71.4	(3.6)	73.0	(3.5)	64.9	(2.7)	69.1	(2.8)	62.0	(2.0)	68.1	(1.3)	−0.19[c]

[a] Period 1 (11.6 days) and period 2 (24.9 days) means were calculated for the days actually in the periods. For other periods, the means were calculated using weekly data only.

[b] Regression slopes are the units change from week to week in standard relays produced per operator per hour. For period 1, the first 1.6 days in week 3 (prior to the move from the regular relay assembly room to the experimental room) were counted as part of week 2. For period 2, which is after the move to the first relay assembly test room, only the last 3.9 days were counted here as week 3. However, the data reported in Appendix 1 are for the weeks as they occurred, without this adjustment.

[c] The relationship of productivity with time (weeks) within the period is significant ($p<.05$).

[d] The relationship of productivity with time (weeks) within the period appears significant ($p<.05$), but significance cannot be tested without correcting for the possible serial correlation indicated by Durbin-Watson test ($p<.05$).

[e] Operator 2 worked only one week during period 23, so the standard deviation among weeks could not be calculated.

[f] Data are only for the first 17 weeks of period 24 (weeks 254 and 270 of the experiment), before the first replacement of an experienced operator by an inexperienced one.

Franke and Kaul's (1978) Model 1 to arrive at variables that allow for the passage of time and explain some of the residual. As only 3% of the periodic variance in productivity was unexplained by Model 1, this analysis of the residuals could hardly, in itself, lead to inclusion of additional variables in models that improve much on Model 1's agreement with the data. Indeed, the residual analysis as carried out does not provide further explanation but, instead, incorporates most of Franke and Kaul's model into the new variables of the alternative models.

What is striking about Schlaifer's (1980) residual Figure 1 and his interpretation of it is that he has not chosen the boundaries and explanations shown by the residual plot but, rather, those suggested by Franke and Kaul's (1978) Model 1. The figure and his new variables, T1, T2, and T3, are apportioned into (1) the span until just before the imposition of managerial discipline, (2) the span between this and the onset of economic depression, and (3) the span after the beginning of the depression. Schlaifer finds that regressions of residuals on time (mid-period week) explain, respectively, 53.8%, 26.4%, and 27.1% of the residual variance within each of these spans. But during span (1), the small-group incentives that were introduced in period 3 could explain a higher 67.4% of the difference in residuals without consideration of time as such. For span (2), examination of Schlaifer's Figure 1 suggests that a much better plot against time would be

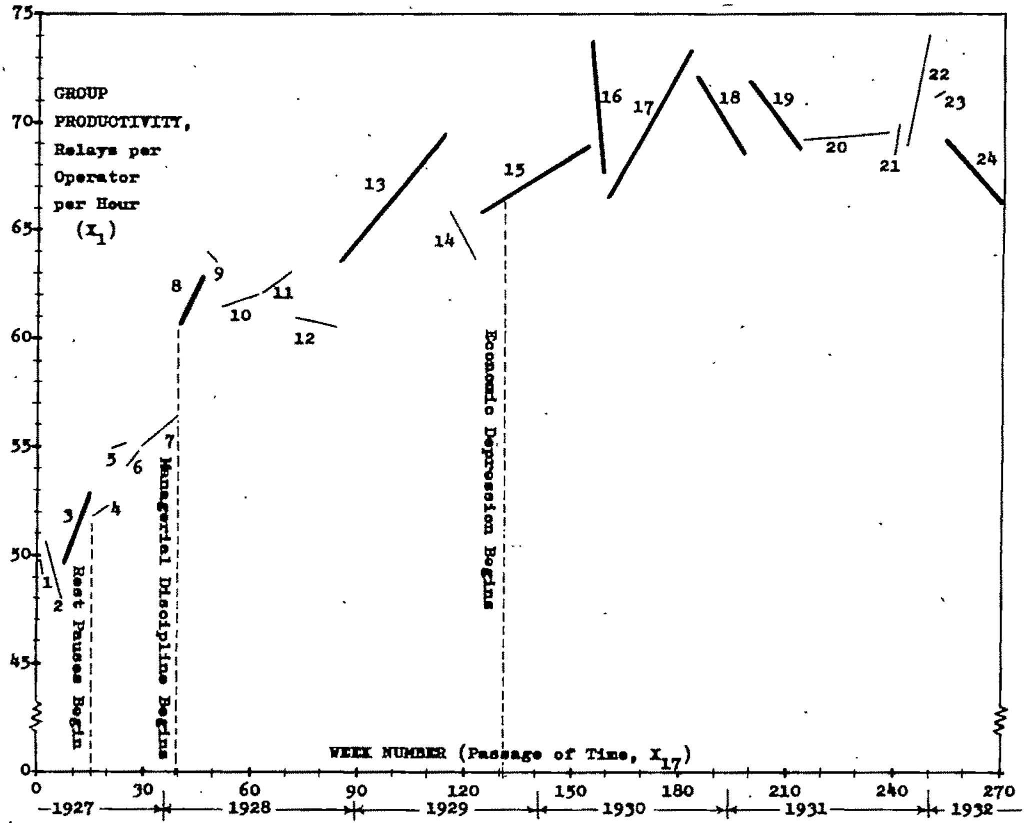

Figure 1. Worker Productivity Trends in Periods 1 to 24 of the First Relay Experiment at Hawthorne

Note: Within-period regression slopes of productivity on time are those presented in Table 1. Heavily shaded regression lines are or appear to be significantly different from horizontal.

from period 8 to period 13, which yields an r^2 of 71.2% as opposed to his 26.4%. (Schlaifer actually calculated his r^2 using periods 8 to 14; for period 8 through the first 26% of period 15—i.e., up to the depression—an r^2 of 42.5% would have been obtained.) For span (3) (apparently calculated by Schlaifer for periods 16 to 23, with a slight error) not much can be done, even if it is enlarged to include periods 14 and 15 and/or period 24. There simply is not much relationship of the residual with time (r^2 = 3.6% from period 14 to 24, 16.6% from period 15—last 74%—to 24, or 28.6% from period 16 to 23).

Instead of contributing much to explanation of productivity differences (and, after all, there was only 3% left to explain), the residual analysis, through its peculiar choice of boundaries, incorporates Franke and Kaul's (1978) managerial discipline and economic depression. This is shown in Figure 2, herein,[4] where variable T1 is composed not only of the passage of time but also of Franke and Kaul's (1978) first variable, as its rise halts abruptly with the imposition of managerial discipline and correlates .84 with it.[5] Even T1's time-increase segment may be part of a Franke and Kaul variable, as much of it parallels the experimentally introduced rise in rest time during span (1) (r = .68). Span (2)'s composite variable T2 also contains the passage of time, but it clearly begins with managerial discipline and ends with the start of the economic depression (r's with these are .72 and .81). In span (3), T3 begins with the depression and is correlated .77 with that categoric variable of Franke and Kaul. Finally (skipping over five of his intermediate and derivative variables), Schlaifer's most encompassing measure of "time," Q4, begins with the introduction of Franke and

---

[4] Figure 2 may be examined vis-à-vis Figure 1's productivity data for initial judgment whether growth in productivity was really "inexplicable," as concluded by Schlaifer (1980).

[5] Cf. Table 3, herein. The intercorrelation measures of multicollinearity presented are over all 257 weeks of work for the group. For those individual operators who worked some weeks fewer, the correlation coefficients may be slightly different.

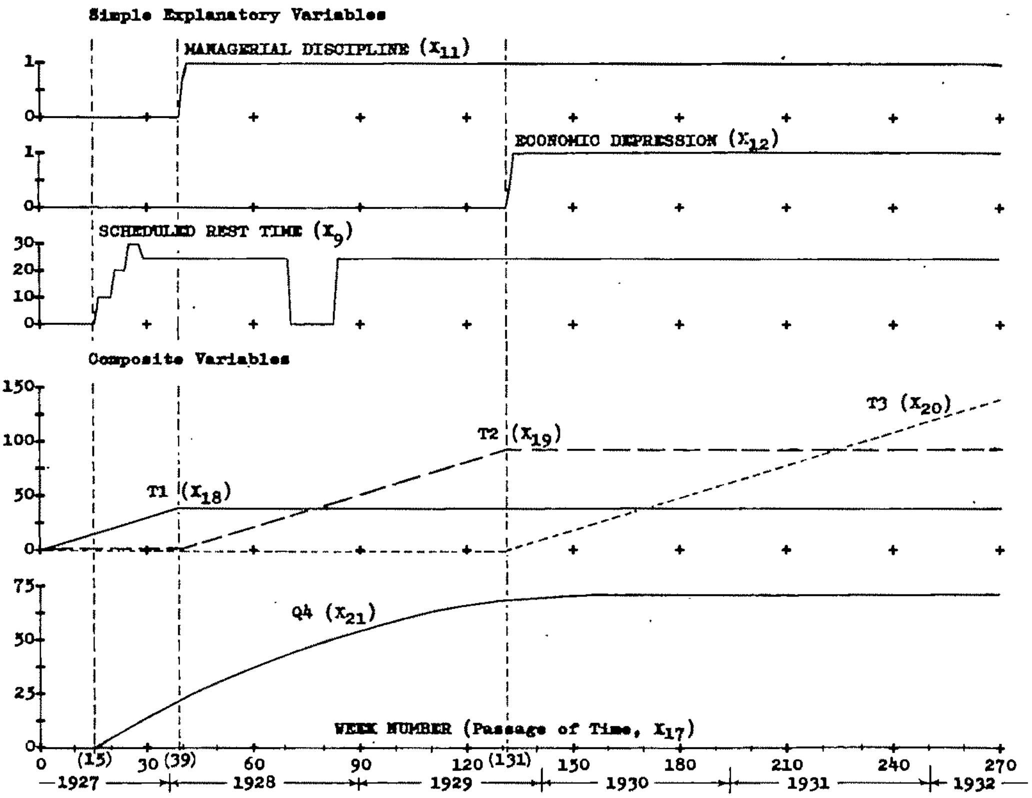

Figure 2. Relationships of Composite Variables to Simple Explanatory Variables

Kaul's (1978) third variable, rest time (r = .54), is shown to rise substantially following managerial discipline (r = .85), and comes nearly to completion (value of 69 vs. the maximum of 71.5) with the economic depression (r = .72). Because the three variables of our (1978) Model 1 intercorrelate from .38 to .46, the high correspondence of Q4 with all three variables is noteworthy.

As is shown statistically and (in Figure 2) graphically, the composite variables introduced seem to yield little additional information beyond that offered by the three variables of Model 1 (Franke and Kaul, 1978). Therefore, further consideration of these Schlaifer variables does not seem necessary. Nevertheless, the "passage of time," which Schlaifer's variables were intended to convey, might have effects which should be investigated further (cf. Schlaifer, 1980:fn.2). In addition, the logarithm of time suggested by learning theory[6] will also be added to Model 1 (Franke and Kaul, 1978) to ensure that the concerns of Schlaifer for the gradually decreasing influence of added time are not neglected.

Analytical Procedures for Time-Series Regression

There are at least three areas of technical concern in the use of statistics for the present endeavor: heteroscedasticity, multicollinearity, and serial correlation. Schlaifer (1980) adjusts data to reduce heteroscadasticity by weighting with the number of weeks in each experimental period, but he does not test any of his models for possible multicollinearity or serial correlation. He observes that the data would not show heteroscedasticity "if we had available the average productivity of the workers in each individual week of the experiment" and that "if the weekly data were available one would be obliged to investigate the error structure". Apparently unbeknown to Schlaifer, the weekly data are available in the original records. Use of them, however, requires some effort due to bulk (there are 313 weeks in all) and due to the need to calculate many of the weekly figures from daily records.[7] In the analyses that follow, only weekly data are used from the beginning of the first period of the first relay experiment in April 1927 through the 17th week of the 24th period in June 1932, after which the experienced operators (first 5A; then 1 and 3; 4; and, finally, 2) were laid off and replaced by inexperienced but more senior operators.[8]

---

[6] Cf. the standard-learning equation applied by Pitcher (1981) to the first relay data.

[7] Similar calculation was required to obtain productivity data for periods 21 to 23 in the study by Franke and Kaul (1978). The averages for periods 1

Clearly, heteroscedasticity can be avoided through assembly of data for about-equal time periods. Similarly, strategies can be used to avoid multicollinearity.[9] In stepwise multiple regression with forward inclusion, the first independent variable chosen is that with the highest t value for its slope coefficient of the dependent variable on it. Variables continue to be added so long as there is a t value (or partial correlation coefficient) that attains the significance level chosen. (In this study, a liberal t of 1.65 is used as lower limit, for $p < .10$, 2-tailed.) The addition of each variable can be restricted to a "tolerance"—the fraction of the variance of a potential variable that is not explained by other independent variables already entered. Tolerance may be set at or above .36 to avoid extreme multicollinearity (in the case of two independent variables, to maintain intercorrelation below .8), or at .75 to avoid moderate multicollinearity (for only two independent variables, to maintain intercorrelation below .5). In the following regression analyses, Model 1 (Franke and Kaul, 1978) is replicated using weekly data (Table 4), and then all meaningful variables including time are allowed to enter without controlling for multicollinearity (Table 5). Finally, meaningful variables are allowed to enter stepwise multiple regressions for the group and for individual productivity, but with control for multicollinearity at a tolerance level of .75 (Table 6). By means of comparison of the results in the final two tables—one without and the other with control for multicollinearity—we may check to see if the major findings are limited to either imperfect approach to the problem of interrelated explanatory variables.

The problem of serial correlation in time-series studies is not that bias is introduced into least squares regression equations, but that tests for significance of regression coefficients, such as those carried out by Schlaifer in his Tables 6 and 7, are inaccurate.[10] Thus, all

---

to 20 were available in the Western Electric progress reports. Daily and weekly data for period 24 are available in the original log books (cf. Franke, 1979b, fn. 3). Weekly data for periods 2 through 13 (to week 24) are provided by the progress reports, but other weekly data for periods 1 and 13 to 23 had to be calculated from daily data in those reports. The 270 weeks of the experiment solely with experienced relay assemblers include 257 weeks of work, 8 weeks of vacation for all operators, and 5 weeks of "days off schedule" due to lack of work. There were 251 weeks during which all five operators were at work.

[8] In his study of period 24 of the first relay experiment, Andrew Spaulding (1980) shows the importance of both learning and managerial discipline (a second episode) to the productivity of the initially inexperienced operators.

[9] Franke and Kaul (1978:629–30) noted, regarding multicollinearity, that "most intercorrelations of these independent variables are smaller than their correlations with the dependent variable." In the AAAS version of the report, they also provided an intercorrelation matrix of independent variables, allowing some further appraisal of multicollinearity (cf. Table 3, herein). In such matrices, intercorrelations above .8 (in absolute terms) are sometimes taken as evidence of extreme multicollinearity, while correlations below .5 indicate the lack of (or low) multicollinearity. Moderate or extreme multicollinearity can lead to unreliable regression coefficients which may change radically upon addition or deletion of a few observations (Elliott, 1973). Perhaps the most commonly employed remedy for multicollinearity is to drop one or more of the offending variables (cf. Dhrymes, 1978). Although this rule of thumb and corrective procedure are faulted (cf. Dhrymes, 1978; Farrar and Glauber, 1967), there seems to be lack of agreement as to more definitive measures and procedures (cf. Hanushek and Jackson, 1977; Kumar, 1975; O'Hagan and McCabe, 1975). Perhaps a better measure of absence of multicollinearity is "tolerance," the fraction of the variance of an explanatory variable that is not explained by prior explanatory variables in the regression equation. Tolerance can be used conveniently in regression with the Statistical Package for the Social Sciences to avoid multicollinearity beyond any set limit by restricting entry of additional independent variables (cf. Kim and Kohout, 1975:346).

[10] A widely used test for serial correlation is that of Durbin and Watson (1950). An equation is deemed possibly serially correlated and thus unworthy of testing for significance if the Durbin-Watson coefficient (DW) is below the upper limit provided by Durbin and Watson (1951:173) at $p < .05$. Then, the continuous dependent variable is adjusted by a factor roughly equal to $1 - DW/2$ (cf. Theil and Nagar, 1961; Wallis, 1972:94). In the experiment, as viewed weekly, none of the independent variables moves continuously; so there seems little point to adjusting them. (Trial correction of the independent variables as well as of the dependent variable shows little difference from correction of only the dependent variable.) Only the 251 work weeks for which all operators were present were used in correction. The process of correction is iterative, with successive estimation of correction factors by which (multiplied times values in time t-1) values in time t are reduced, until the corrected data yield an equation with nonsignificant Durbin-Watson coefficient. In response to Schlaifer's (1980:fn.3) concern over the meaning of serial correlation, note Durbin and Watson's (1950:410–1) focus on the violation of the least

Table 2. Experimental Correlations—Group and Individual Productivity[a]

[a] These Pearson product-moment correlations are for all weeks common to each pair of variables indicated (257 weeks for the group and for operators 1A+1, 254 for operators 2A+2, and 256 weeks for operators 3, 4, and 5+5A). Two independent variables treated in the earlier paper (Franke and Kaul, 1978) are excluded here: variable (7), weeks per period, and variable (10), voluntary rest time. (At least some of the information in weeks per period is conveyed through use here of weekly data. Voluntary rest time may be interpreted as a dependent variable which resulted from fatigue or perhaps from dissatisfaction. For the group over 23 periods, it is correlated −.84 with scheduled rest time.)

[b] Hours per day times days per week, minus scheduled rest time.

[c] Change indicated = 1, otherwise = 0.

[d] Operator 5 was replaced voluntarily by operator 5A from week 6 of period 14 to week 2 of period 17, and from week 2 of period 24 until operator 5A was laid off in week 18 of period 24. Operator 5 did not return again to the experiment.

[e] During experimental periods 16, 17, and 18, the operators' order of seating was changed from the usual 1-2-3-4-5 to 4-2-5-3-1. Judging from the operators' comments in the Western Electric records (cf. Franke, 1979b, fn. 3) and from the selections chosen by Whitehead (1938:I), this change substantially affected social relations and satisfaction. This variable was not included in the analysis of Franke and Kaul (1978).

equations to be presented in the three regression tables that follow are those uncorrected for serial correlation. But significance tests are performed on corrected equations, for whose regression coefficients t-tests and significance levels are reported. Variables are not entered in equations if they showed multicollinearity in the basic equations (when the tolerance re-

---

squares assumption that "successive errors are distributed independently of one another," and their question as to why they usually are not distributed independently using time series data. Clearly, the answer often is that there is some lack in model specification. Pindyck and Rubinfeld (1976:107) point out that positive serial correlation frequently occurs "because of the high degrees of correlation over time present in the cumulative effects of the omitted variables in the regression model." In response to Schlaifer's footnote 4, it may be noted that the approximate transformation called T_2 by Johnston (1972:261) provides "generally a close approximation" to the exact transformation, T_1, and is useful in an iterative process such as that described herein or by Johnston (1972:262–3).

striction is used); also, variables are not entered if they are nonsignificant (p > .10, 2-tailed) after correction for serial correlation.

I summarize—if I may—the methodological approach described here: Weekly data from the first relay experiment have been introduced in Table 1, Figure 1, and Appendix 1; the roots of Schlaifer's composite variables have been shown to lie within the experimental variables delineated by Franke and Kaul (1978); means of avoiding or correcting for the statistical problems of heteroscedasticity, multicollinearity, and serial correlation have been introduced for use in the analyses that follow. The stages of analysis that can now be undertaken will be those of the study by Franke and Kaul (1978, AAAS and American Sociological Review versions): Zero-order correlation of dependent variables with independent variables (Table 2); zero-order intercorrelation of independent variables (Table 3); and regression models that first replicate our Model 1 (Table 4), then allow entry of the "passage of time" and all other meaningful independent variables without controlling for multicollinearity (Table 5) and, finally, control for multicollinearity and attempt to maximize variance explanation using the weekly data (Table 6).

RESULTS

Zero-Order Relationships

The productivity measures over the 257 work weeks of the first relay experiment for the group and the five individual operators (with replacements) are correlated in Table 2 with each other and with all independent variables. Substantial (over 25%) variance explanations by single independent variables are provided by managerial discipline, the depression, and (except for operators 5+5A) by scheduled rest time. The depression lag of just over six months—named "cutback" as there was a reduction in working hours then to 40 hours per week—related better than the depression itself to the productivity of operators 5+5A, but less well for other operators. The simple passage of time and three of the four composite variables also related substantially to productivity.

The interrelationships of independent variables in Table 3 indicate little likelihood of multicollinearity for the independent variables of Franke and Kaul's (1978) Model 1 (variables 9, 11, and 12), but there are eleven instances of high intercorrelation for the two alternative models (involving, primarily, variables 18 through 21).

Replication of Model 1 with Weekly Data

Replication of Franke and Kaul's (1978) Model 1 period-by-period equations in Table 4 using the weekly productivity data yields slightly lower variance explanation—ranging from 71% for operators 3 and 4 up to 86% or 87% for the group and for operators 1A+1 and 2A+2 (for whom operator replacement in period 8 contributed to the strength of the "managerial discipline" effect). Serial correlation could be corrected for all individual operators and for the group, and effects of managerial discipline and the depression were significant. Regression coefficients for managerial discipline were considerably higher when weekly data were used than when periodic data were used, while effects of the depression were lower. Coefficients for the effects of rest time were generally not much different whether using data for weeks or for periods, but this variable was not significant for operators 5+5A. For the group as a whole, managerial discipline appears to have contributed about 10 additional units produced per worker per hour, the depression about 5 units, and rest time of 25 minutes per day about 4½ units, for a total of about 19 additional units per hour per worker. This accounts for 86% of the rise in group productivity from base period 1 to peak period 22 (see Table 1).

Addition of Time and Other Variables without Control for Multicollinearity

As shown in the intercorrelation matrix of Table 3, variable 17 (the passage of time, measured in chronological weeks of the experiment) is highly collinear with the depression (variable 12) and moderately so with managerial discipline (variable 11). Thus, in the expanded regressions of Table 5, which include time as well as variables 4 to 6 and 8 to 16 (see Table 2) without controlling for multicollinearity, time enters first in the equation for the group. For individual operators, however, other variables enter prior to time—managerial discipline is first in four cases and second in the fifth.

Through inclusion of further variables, variance explanation is increased for the group from 87% (Table 4) to 92% (Table 5), and increases for individuals are similar or greater. In all cases, the effect of time is significant, but the effects of managerial discipline (with one exception) and rest time remain, as well. Models were also attempted in which the logarithm of time was substituted for time, approximating the shape of learning curves in industrial situations.[11] For the group, and for each operator, the resulting variance explanation was lower than when the straight-line passage of time was included. (The model for the group only is presented in fn. b to Table 5.)

The high multicollinearity in each model of Table 5 makes interpretation ambiguous. Most models show sign reversal and diminishing of coefficients of early-entered variables as multicollinear later variables enter. Some control of multicollinearity would be useful in sorting out the statistics of the first relay experiment. However, there is no sure way to exert this control. Therefore, the following results are presented as a possible approach, for juxtaposition with the multicollinear results of Table 5.

Comprehensive Models without Multicollinearity

In these regressions, all work-schedule, rest-pause, and categoric-change variables are free to enter, subject to the limitation that they show a .75 tolerance and significance at $p < .10$ after correction for serial correlation. Time and, then, the logarithm of time were added to the potential explanatory variables in separate sets of runs. The resulting comprehensive models for the group and for individual operators are shown in Table 6. In no case did a model that included a measure of the passage of time provide the highest variance explanation.

For operators 2A+2 and 3, Franke and Kaul's (1978) Model 1 gave the greatest explanation. For operators 5+5A, an addition to Model 1 is variable 14: the replacement of operator 5 by the initially less-experienced operator 5A led to a drop of some 8 units per hour from the productivity rate of operator 5, and was reflected by a drop of 1-1/3 units in the average group rate. For operators 1 and 4, variable 16 is added to Model 1: the movement of operator 1's seat away from operator 2 (the group leader) seems to have resulted in a decrease of 2 units in operator 1's productivity, while the move placing operator 4 next to operator 2 led to an increase of over 4 units for operator 4. (This operator, who usually produced the lowest quantity of defective products, seems to have been stimulated even by the challenge of coping with poor quality raw materials, as shown by the positive entry of variable 13.)

DISCUSSION

In these correlations and regressions, the specific factors of Model 1 (Franke and Kaul, 1978) provided the most powerful and consistent explanations of productivity differences for the experiment with experienced assembly workers in the first relay test room. In other experimental situations at Hawthorne, similar specific factors could be identified as significant to productivity.[12] The demonstration of

		$(p < .001)$	$(p < .01)$	$(p < .001)$	Factor = 0.5	
4	51.39	$+ 10.03 X_{11}^{(1)}$	$+ 4.23 X_{12}^{(2)}$	$+ 0.23 X_9^{(3)}$	70.61%	0.78
		$t = 7.36$	$t = 4.61$	$t = 4.17$	(45.60%)	(2.01)
		$(p < .001)$	$(p < .001)$	$(p < .001)$	Factor = 0.5	
5+5A[e]	51.89	$+ 4.56 X_{11}^{(2)}$	$+ 6.36 X_{12}^{(1)}$	—	50.36%	0.30
		$t = 2.49$	$t = 6.18$		(21.77%)	(1.96)
		$(p < .02)$	$(p < .001)$		Factor = 0.7	

[a] These regression equations replicate week by week the period-by-period analyses of Franke and Kaul (1978:Tables 2 and 3). Superscripts in parentheses in the equations indicate order of entry of variables in stepwise multiple regression.

[b] All regression equations presented in this report use the time-series productivity data in Appendix 2 without correction, and all show significant serial correlation so that significance tests cannot be performed. The t values and significance tests shown are for the equations corrected using the factor indicated (cf. Franke and Kaul, 1978:628).

[c] After correction for serial correlation, this and all other Durbin-Watson coefficients presented show nonsignificant serial correlation. The equation after correction for serial correlation is used only to determine significance levels, which is possible because the data have been made serially independent. The corrected equations are not reported here, but their variance explanations and Durbin-Watson coefficients are shown in parentheses.

[d] Replication with weekly data of the independent multiple regression for Operator 3 in Table 3 of Franke and Kaul (1978) reverts to Model 1 after correction for multicollinearity.

[e] After correction for serial correlation, X_9 is nonsignificant. The replication with weekly data of the independent multiple regression for Operators 5+5A in Table 3 of Franke and Kaul (1978) yields:

		Defective Raw Mtls.	Economic Depression	Net Hours per Week	Managerial Discipline
$X_{1\text{-}(5+5A)}$	$= 57.29$	$- 7.75 X_{13}^{(2)}$	$+ 5.59 X_{12}^{(1)}$	$- 0.12 X_6^{(4)}$	$+ 5.71 X_{11}^{(3)}$
		$t = 9.80$	$t = 7.44$	$t = 1.71$	$t = 5.93$
		$(p < .001)$	$(p < .001)$	$(p < .10)$	$(p < .001)$

Variance explanation (R^2) = 76.21%, Durbin-Watson coef. (DW) = 0.70 (after correction for serial correlation using factor of 0.5: R^2 = 57.73%, DW = 1.81)

Note that the order of variables presented above is that for the equation using periodic data (from Franke and Kaul, 1978:Table 3), and is different from the order here using weekly data, indicated by superscripts in parentheses. (There is moderate multicollinearity—indicated by tolerance of 0.49—at the entry of the fourth variable, net hours per week. The variance explanation before that entry is 75.50%.)

(ii) in the illumination experiments—from illumination increases and from "social hysteresis," or reluctance to retreat from productivity levels once attained (Wiljanen, 1979);

(iii) in the second relay and mica splitting experiments—from small group incentives and from fatigue reduction (Franke and Kaul, 1978:fn.9); and

(iv) in the 24th period of the first relay experiment (with inexperienced operators who clearly had something to learn)—from the logarithm of learning time and from managerial control (Spaulding, 1980).

these tangible causes of worker productivity contradicts any suggestion that resorts to the possible effects of "human relations" or placebo mechanisms upon productivity.

A much more detailed set of data has been used here than was used in the first attempt to test statistically the effects of the major Hawthorne experiment upon worker productivity. As it is difficult to maintain as high a variance explanation for 257 weeks as for 23 periods,[13] it

[a] For the group and each (pair of) individual(s), the order of entry, model coefficients, and tolerance at entry are presented for the original model; t-test and significance level are shown for each independent variable that was significant at entry for the model after correction for serial correlation. Since variables are not restricted from entry even though multicollinear, there are some sign reversals and diminishing of earlier effects of independent variables as results of multicollinearity.

[b] Extreme multicollinearity for X_{12L} and X_4. Multicollinearity may be responsible for sign reversal of X_{12L}. The model when log of time is substituted for time is (in order of entry):

	$X_{1\text{-}G} = 58.91$	$+10.22(\log X_{17})$	$+3.61\ X_{11}$	$-2.25\ X_4$	$+0.17\ X_9$
Tolerance:		—	.36	.76	.66
t=		10.28	3.02	4.17	3.79
p <		.001	.01	.001	.001

	$-5.29\ X_{15}$	$+1.41\ X_{16}$	$+0.10\ X_6$	$-0.59\ X_8$
Tolerance:	.46	.60	.77	.25
t =	3.82	3.02	2.53	1.78
p <	.001	.01	.02	.10

$R^2 = 90.41\%$, DW = 0.96 (after correction for serial correlation using factor of 0.4: $R^2 = 81.36\%$, DW = 1.84).

[c] Extreme multicollinearity only for X_{12}.

[d] Extreme multicollinearity for X_{17} and X_{121}. Multicollinearity may be responsible for the diminishing of the effect of X_{12} and for sign reversal of X_{12L}.

[e] Extreme multicollinearity only for X_8. Multicollinearity may be responsible for its sign reversal.

[f] Extreme multicollinearity for X_{17} and X_8. Multicollinearity may be responsible for sign reversals of X_{12} and X_8.

[g] Extreme multicollinearity for X_{17}, X_{12}, X_{13}, and X_4. Multicollinearity may be responsible for the diminishing of the effect of X_{11} and for the sign reversal of X_{12L}.

is encouraging that for the group there is a drop if only 10% using the Franke and Kaul (1978) Model 1—from 97.1% to 87.2%. In the comprehensive models of Table 6, there are modest drops in variance explanation from those in Franke and Kaul's (1978) Table 3 for operators 1A+1, 2A+2, and 5+5A, a large drop for operator 3, and about the same explanation for operator 4—traceable to consideration here of the change in seating position. This move placing operator 4 next to the informal group leader for 10 months of the experiment appears to have contributed 4.41 units per hour to operator 4's productivity. Considering as a part of managerial discipline the continuing leadership of operator 2 as "straw boss," there is a total managerial discipline effect on operator 4 of 14 units additional hourly production, equivalent to the effects for operators 1A+1 and 2A+2 (where replacement or "personnel selection," as well as disciplinary example, was at work).

This reappraisal supports the earlier explanations of the changes in worker productivity at Hawthorne (Franke and Kaul, 1978; Franke, 1979b). The main factors affirmed here are managerial discipline, the economic depression, and the provision of rest pauses. While the potential of the last variable for reducing fatigue and increasing productivity has been well established—at least since the concept of scientific management enjoyed currency and "fatigue laboratories" existed in the early decades of this century—the mechanisms of the variables labeled managerial discipline and economic depression are less obvious.

Managerial Discipline

Managerial discipline in the first relay experiment (Franke, 1979b: 862-4) included threats and punishment by management and the provision of close "supervision" by the informal—but clearly dominant and domineering—group leader (replacement operator 2). It is not clear from the available literature just why managerial discipline was imposed on January 25, 1928, when both previously and subsequently other behavioral and productivity problems with various operators

---

titudes, health, weather, holidays, etc., further variance explanation could be expected. Indeed, it is apparent from looking closely at the weekly data that the proximity of certain holidays (especially Christmas) did have adverse effects on productivity, and Whitehead (1938) has reported some adverse effects from lack of sleep. Detailed consideration of these short-term factors would be especially important to statistical analysis of the day-by-day productivity data.

did not prompt major intervention by management.

The surviving records of the experiment might, however, provide an answer. Comments of operators 1 and 2, later relabeled 1A and 2A, as recorded for January 23, 1928, indicate that they were restricting their output—a common practice in many industrial facilities and, for that matter, elsewhere at Hawthorne (cf. Homans, 1950). In this experiment, though, restriction of output was viewed as a serious offense by management and led to summary removal of the offenders. This lesson obviously was learned by the other operators, and it is reasonable to assume that it accounts for much of the higher productivity levels attained during period 8 and later.[14] To substantiate this interpretation of the disciplinary intervention, the reader is referred to the documents that record the dialogue of the original operators 1 and 2 and the specific actions and opinions of management on January 23, 24, and 25, 1928.[15]

As discussed earlier (Franke, 1979b:862–3; Franke and Kaul, 1978), managerial discipline was not simply a matter of replacing two obstinate workers by two better ones. The intervention also provided a disciplinary example and closer supervision internal to the group. The day-by-day descriptions of the experiment in the original documents underpin this interpretation, which is given additional support by the regression coefficients for remaining operators 3, 4, and 5+5A in Tables 4, 5, and 6, above.[16]

Economic Depression

That the economic depression seems to have had early effects on productivity is puzzling, since workers might not have been expected to be particularly aware of the importance of the crash on October 24, 1929. However, two pieces of information help explain their sensitivity to this stimulus. First, as described by Whitehead (1938:I:137), the operators had been made aware in June 1929 that lessened volumes of work (for reasons that had nothing to do with the depression) might affect their schedules and earnings. Second, the Hawthorne records show that some of the operators in the test room as well as workers elsewhere in the plant were themselves participants in the stock market,[17] so that they could have been aware of the crash as an economically disturbing event. Thus, it is by no means implausible that the beginning of the economic depression had some influence upon the participants in the experiment. Nevertheless, the present analysis shows this influence on productivity to have been weaker than was indicated earlier (1978) by Franke and Kaul. In addition, as shown in the alternate comprehensive model for operators 5+5A in Table 6, the decrease in volume of work six months later may have been as important as was the beginning of the depression for operator 5A.

CONCLUSION

There was a 45% increase of worker productivity in the first relay experiment at Hawthorne. Most of the week-by-week differences in productivity rate during the experiment have been explained (for the group as well as for the individuals in it) by specific factors that are documented as having occurred during the experiment—managerial discipline, depression, and rest periods. Contrary to the conclusions reached by Schlaifer, one need not rely on "unmeasured variables for which time is a proxy" to explain productivity differences. In fact, the inclusion of time as a variable does not add to explanation once the few pertinent experimental variables are considered.

Since, in this case, digital computers and statistical methods systematically applied to voluminous experimental data do seem capable of contradicting long-held beliefs by providing a reliable description of what happened at Hawthorne, it is surprising that a statistical exercise such as Robert Schlaifer's could assert nothing more than "the importance of the effect of the passage of time." Rigorous testing with data for weeks as well as for periods, and for individuals as well as for the group, shows clearly that specific experimental variables did lead to the achieved increases in productivity.

[14] Cf. Figure 1 for the group and Table 1 and Appendix 1 for individuals.

[15] Cf. *Daily History Record,* microfilm reel 1, listed as box 2, folder 7.

[16] In Table 6, the regression coefficients under managerial discipline average 7.0 for the continuing three operators, as against 14.6 where replacement occurred in period 8. The disciplinary example and internal supervision effect of 7.0 is just under half the full effect for operators 1A+1 and 2A+2, suggesting that the magnitude of the disciplinary aspects as such nearly equals the effect of replacement where it occurred. Since the disciplinary aspects of managerial discipline could affect all of the operators, they then can be held to account for most of the impact of the variable at the group level.

[a] Independent variables included in the regression attempts are variables 4 to 6, 8, 9, and 11 to 17 (described earlier in Table 2.) The "passage of time" is included, but not the composite variables (18 to 21) which are based on two or more of the simple variables and, thus, are highly multicollinear and indistinct in meaning (cf. Figure 2 and Table 3, shown earlier). The equations presented in Table 6 are the results of (1) avoidance of multicollinear variables by entering variables only if their tolerances (variance fraction not explained by independent variables already in the stepwise regression) are 0.75 or higher and (2) avoidance or removal of remaining variables which, after correction for serial correlation, have regression coefficients which are not significant at $p < .10$ (2-tailed).

[b] This equation results from stepwise multiple regression without inclusion of the passage of time. Its variance explanation (86.34%) is greater than that with the passage of time included (79.98%), in which were entered variables 17, 9, 16, 15, and 13 (DW = 0.48). In the third step of the equation in Table 6, it is X_8 (rest stops) rather than X_9 (rest time) that enters, since the tolerance for X_9 is 0.74980—just below the 0.75 limit set. Because number of rest stops explains less productivity variance than does rest time, the total explanation of this model is slightly less than that of Model 1 in Table 4. (However, for all individuals, the variance explanations in Table 6 exceed those in Table 4. The Table 6 explanations are also greater than those by the equations in Table 5, if these equations are carried further to correct for multicollinearity as has been done in Table 6.) Further comprehensive model testing inserting the log of the passage of time in place of variable 17 yields variance explanation of 85.37%, higher than when using variable 17 but lower than the explanation using models not including a measure of time.

[c] This equation is superior in variance explanation to that run when variable 12L is used (which then enters in preference to variable 12). This independently arrived at but slightly inferior model is:

Comprehensive Model for Operators 5 + 5A:

Appendix 2. Guide to Hawthorne Records

This is a brief guide to the documentation of the Hawthorne studies. Complete microfilm records of the studies are preserved on microfilm at the Library of the University of Wisconsin–Milwaukee. The original Hawthorne documents were obtained from the Hawthorne plant of the Western Electric Corporation during the spring of 1977 by Richard H. Franke, James D. Kaul, Ruth Zubrensky, and George Carian. The documents were microfilmed as historical records by Stanley I. Mallach and Steven Smith of the Library, with particular attention to recording all penciled markings, paper-clipped notes, and the like, preserving in many instances evidence which seems never before to have been noted. Particularly important were the good offices of William C. Roselle, Director of the UWM Library, and of E. L. Byrom and Florence Hybl in the Western Electric Public Relations Department at Hawthorne. Copies of the microfilm are in the Gordon Library at Worcester Polytechnic Institute, the Baker Library at Harvard, and in the Hawthorne Plant.

The records are presented on seven reels of microfilm representing the seventeen original boxes of experimental data, reports, correspondence, meeting minutes, articles, interviews, and conversations. This appendix orders the records by topic, showing to the left the microfilm reel number and the original box number and folder number of each document, as specified on the microfilm. For a more detailed guide, see Mallach and Smith (1977).

LOCATION			TOPIC
Reel	Box	Folder	*Records*
			(1) ILLUMINATION
1	1	9	Effects of illumination on industrial efficiency—1920s.
			(2) FIRST RELAY
1	1	3	Progress Report 1, 12/3/27: rest and hours.
1	1	4	Progress Report 2, 2/25/28: rest and hours.
1	1	5	Progress Report 3, 8/15/28: rest and working conditions.
1	1	6	Progress Report 4, 5/11/29: rest and working conditions.
1	1	7	Progress Report 5, 1931, never completed: miscellaneous information.
1	1	8	Pennock's notes on the test group conference in 1927—goals outline.
1	2	1	Test-period schedule; piece rates; conversion factors—1927 to 1932.
1	2	2	Daily temperature and humidity record—1927 to 1930.
1	2	3	Vascular skin reaction readings: fatigue measurement.
1	2	4	Mayo report on blood pressure readings for operators.
1	2	5	Menus and meal records for operators—1927 to 1928

Appendix 2. (Continued)

LOCATION			TOPIC
Reel	Box	Folder	*Records*
1	2	6	Daily record of operators' living habits—1927
1	2	7	Daily history record of test room, vol. 1—1927 to 1933.
2	3	1	Stock list and bench layout—1931.
2	3	2	Operator comments—1927 to 1930.
2	3	3	Operator comments continued—1928 to 1930.
2	3	4	Summary of weekly activity in test room—8/8/31 to 12/6/31.
2	3	5	Personal histories of operators—1927 to 1930.
2	3	6	Relationship between hours of sleep and speed tests—1930.
2	3	7	Relationship between voluntary rest and output quality—1930.
2	3	8	Relationship between quantity and quality of output—1931.
2	3	9	Study of output quality—1930 to 1931.
2	4	1	Study of operator reactions to shorter work week—1930.
2	4	3	Temperature and humidity studies—1927 to 1931.
2	4	4	Attitude questionnaires from operators—1929 to 1931.
2	4	5	Operator 1 interviews—5/31 to 5/32.
2	4	6	Operator 2 interviews—5/31 to 6/32.
2	4	7	Operator 3 interviews—6/31 to 6/32.
3	4	8	Operator 4 interviews—6/31 to 5/32.
3	4	9	Operator 5 interviews—6/31 to 2/32.
3	5	1	Interviews with operators—1933.
3	5	2	Study of operator removed for health and attitude reasons—1928.
3	5	3	Test-room observations, vol. I–1/32 to 3/32.
3	5	4	Test-room observations, vol. II–4/32 to 6/32.
3	5	5	Comparison of 5 day vs. 4½ day week, study of rest periods—1930.
			(3) SECOND RELAY (also see FIRST RELAY)
2	3	11	Output data—1928 to 1929.
2	3	12	Reasons why workers restrict output—1931.
			(4) MICA SPLITTING
3	6	1	Daily output variations—1928.
3	6	2	Attendance irregularities comparison between regular department and test room—1927 to 1930.
3	6	3	Production comparison between test-room and nontest-room workers—1928 to 1930.
3	6	4	Operators' comments—10/28 to 11/30.
3	6	5	Report on time required for inexperienced operators to become efficient—1928.
3	6	6	Comparison between a.m. and p.m. hourly output—1928.
3	6	7	Daily routine of mica splitting and armature straightening operators—1930 to 1931.
3	6	8	Case study of an operator's removal from experiment—1929 to 1930.

WELSH POLITICAL MOBILIZATION: A COMMENT AND A NOTE*

(COMMENT ON RAGIN, *ASR*, AUGUST, 1979)

In a recent study, Ragin (1979) tested various hypotheses related to ethnic political mobilization in Wales. Using electoral results, he analyzed three different theories that could possibly explain such mobilization, with part of the analysis based on the inhabitants' identification with the traditional Welsh culture of the area as opposed to the English cultural alternative. The basis of his analysis rested on using voter support for two parties that have been active in Wales in various elections and a number of socioeconomic characteristics of the shires (counties) in the area. The key dependent variables used were support for the Liberal Party for the general elections from 1935 to February, 1974 (ten elections), and for the Plaid Cymru, the Welsh nationalist party, for general elections from 1950 to 1974 (eight elections). The nationalist party has had an obvious ethnic appeal for at least some of its supporters, and Ragin argued that the Liberals made efforts to present themselves as a party that favored Welsh interests. The Liberal Party's longstanding commitment to decentralization and even to federalism are factors that justify this view to at least some extent. Ragin's effort to test the relevance of the three (at times) competing theories for underlying ethnic mobilization has a distinct value, and there is no reason to disagree with the theoretical worth of his study. There are also no compelling reasons to question the statistical methods that he chose to use since they appear to be appropriate ones. There are, however, some serious questions in regard to the areal basis of his data and the resulting aggregation of information, and some questions related to missing observations and how they were handled. His data base is sufficiently weak in some ways so as to preclude uncritical acceptance of his results. The goal of this comment is twofold. First, the problems of data management in Ragin's study will be discussed, and the comments made may provide an additional perspective from which to view his results. Second, some further information in regard to the impact of Welsh culture on voting will be presented and, hopefully, it will prove useful for future studies of ethnic mobilization in Wales. Finally, a few observations will be offered on the new data that are presented.

In order to test the various hypotheses in question, Ragin (1979) used the 13 Welsh shires as his areal base. These proved to be the smallest areal units for which both voting results and socioeconomic statistics could be gathered. Voting results are available at the constituency level, but the socioeconomic data in the United Kingdom are reported for only shires and boroughs (cities or component parts of larger urban areas). Unfortunately, the 36 Welsh election constituencies do not adapt well to this type of format. While no constituency includes parts of 2 or more shires, the shires contain a highly variable number of electoral districts. One constituency consists of 2 relatively sparsely populated shires, while 5 other shires each constitute an electoral district. Four shires have 2 constituencies, 1 basically rural and the other primarily urban. The last 2 shires contain the bulk of both the population and of the constituencies. Monmouth has 6 while Glamorgan[1] alone has 16 of the total of 36. Thus, 1 shire accounts for almost half of the variation among the electoral districts but serves as only one observation. In regard to any analysis of ethnic mobilization, there may be as many phenomena occurring within Glamorgan as there are within Wales as a whole. While weighting measures in the regression analyses alleviates some of the difficulty in this regard, these multiconstituency shires present another problem for analysis in terms of the socioeconomic variables that Ragin used. Aggregating at the shire level for Glamorgan combines large urban areas such as Cardiff, smaller urban areas, the mining valleys of the south, and rural areas into one data observation. It is more than reasonable to expect differing characteristics for the different types of constituencies. Furthermore, the urban nature of some constituencies was enhanced by the practice, prevalent in Wales before 1950, of forming electoral constituencies out of nonadjacent urban communities in a given shire and leaving the remainder of the shire, basically rural, to form another electoral district. In sum, the use of the shires as the basic areal unit, however necessary from a data-base point of view, obscures a great deal of important variation, particularly given the hypotheses that were compared and tested.

There is another basic problem that arises in regard to the data (Ragin, 1979) used. As far as

I would like to acknowledge the help of members of the U.S. Bureau of the Census, especially Dr. Diana DeAre, in the collection of the data on Welsh speakers through the use of the library holdings in Washington, D.C. I also appreciate the extremely helpful comments of an anonymous referee.

[1] Shire and constituency names used are the old designations, not the new Welsh (Celtic) equivalents.

can be discerned, no account was taken of the fact that it has been many years since the Liberal Party contested all the constituencies in a general election. While a party's decision *not* to field a candidate might reflect a perceived lack of support in a given area, results for the Plaid since 1970 would indicate that there is at least a minimum level of support for the two parties in all constituencies as the party has always gotten some votes. Thus, if the lack of a candidate from one or both of these parties in some constituencies was deemed to indicate zero support, ethnic mobilization was understated, perhaps seriously in some cases. Using a zero value in the various statistical analyses, or having some values reflecting the inclusion of zeros for the aggregated shire totals, undoubtedly induced a margin of error into the statistical results. At the very least, it would be useful to know if this situation were considered and what steps, if any, were made to correct for it. The importance of dealing with this factor can be demonstrated by the 6 general elections between 1950 and 1966. In these elections the Liberals contested only 71 seats out of a possible 216 contests, only 32.9%. Thus, for over two-thirds of the seats in question, a Liberal candidate was not present. For these 6 elections the Plaid contested only 79 seats—36.6% of those possible—although the nationalists did contest all the seats from the 1970 general election, on.

In addition to the above consideration, tactical voting decisions on the part of Liberal supporters, for example, to vote for a nationalist candidate in the absence of their own candidate would clearly affect the level of support for the Plaid. The reverse of this situation could also have occurred prior to 1970 with nationalist sympathizers or potential supporters voting for a Liberal candidate if one were present and a member of their preferred party were not running. This possibility is important because the analyses (Ragin, 1979) using Liberal vote percentages and Plaid percentages were run separately, and the results of the regression analyses tended to support different hypotheses. Indeed, it might have proven enlightening to have joined the vote levels of the two parties, with corrections for the missing observations, for a third regression analysis—to see what relationships then existed. Again, using the 6 elections from 1950 to 1960 as an example, Liberal candidates and nationalist candidates overlapped in 32 cases, slightly higher than expected given the number of candidates of the two parties, but, in 86 cases, there was a candidate of only one of the parties (and, in 91 cases, a candidate of neither). Thus, there was ample opportunity for tactical voting to occur. It does remain likely, however, that such a third regression analysis might be ambiguous, by itself, as the Liberals and the nationalists might have been tapping different areas of support—particularly considering that the Liberal party has other bases of support, given its position as a party competing throughout Great Britain.

A few comments as to how the aggregation problem and the lack of candidates may have affected Ragin's (1979) findings can be ventured, although the lack of socioeconomic data at the constituency level will make them somewhat speculative. Ragin found agricultural employment associated with support for the Liberals. The 6 general elections used before can demonstrate at least one reason for this finding. Of the 10 large constituencies in the north and west which have an agricultural employment sector of some magnitude, the Liberals put up candidates quite frequently. They contested all 6 elections in 4 constituencies. One of them, Montgomery, had been a continuously held Liberal seat from 1900 until the general election of 1979. Of the 60 contests in these constituencies, Liberal candidates were present in 41 of them, 68.3% compared to their 32.7% average for Wales as a whole. By contrast, in these same elections they fielded only 11 candidates in the 96 contests in Glamorgan and only 3 in the 36 contests in Monmouth, the more urbanized and industrialized shires in south Wales. The lack of candidates in these areas of Wales might go a long way toward explaining Ragin's finding of a negative relationship between Liberal support and the peripheral industries of mining and heavy industrial manufacturing. To the extent that the party's choices as to which constituencies held the most support for them were correct ones, Ragin's findings may be in the appropriate directions, but they would undoubtedly be weaker.

The Welsh nationalists' selectivity in presenting candidates for the 1950 to 1966 period was somewhat different. Their candidates overlapped with the Liberals in the agricultural north and west, but they were more prevalent in Glamorgan, particularly in the mining areas in the northern part of the shire. The association of nationalist support with tertiary industry might reflect the aggregation of socioeconomic data at the shire level. In the 1970 and February 1974 general elections, the nationalists' greatest strength in Glamorgan was in the mining areas (Merthyr, Caerphilly, Aberdare, and Rhondda), but not in the urban areas and the semiurban areas in the south. It is thus possible that the nationalist support was more related to peripheral mining industries than tertiary industry.

In sum, the above data problems induce

Table 1

[5] 1970 constituencies.

some doubt in regard to Ragin's (1979) overall results. Perhaps these problems explain some of his relatively unexpected findings and support for different hypotheses depending upon which party's support was analyzed as their selective presentation of candidates varied so much in Glamorgan—and one shire contributing most to the regression results, given the weighting process used. It is also equally possible that the consideration of these factors might have changed some of the results. Thus, notwithstanding an excellent effort to test some important theories on ethnic political mobilization in the Welsh context, the results need to be viewed with caution.

The second object of this comment is to provide some additional information at the constituency level for one of the key indicators associated with the Welsh cultural tradition—the proportion of the population that speaks Welsh as, at least, a second language. The proportion of Welsh speakers in each constituency in the 1970s can be determined through the use of a special census publication of the government of the United Kingdom (Office of Population Censuses and Surveys, 1973) and from information on the components of the various constituencies (Craig, 1972). Similar information for the 1960s is already available in Philip (1975). The presentation of this information may prove useful for future tests or retests of the hypotheses on ethnic political mobilization. The breakdown of Welsh speakers in the constituencies for the 1970s is presented in Table 1. As is immediately obvious, there are very clear differences between some of the constituencies within the same shire. The more urban constituencies contain individuals who are less likely to know Welsh, while the nearby rural areas have a much higher proportion of Welsh speakers and writers. The wide variations among the constituencies in Glamorgan are particularly noteworthy. While none of the constituencies in Glamorgan have the highest levels in Wales, some are among the lowest.

The information presented in the table can be used, initially, to test the relationship of the identification with the Welsh cultural tradition as indicated by Welsh speaking ability and support for the Plaid. Ability to write Welsh, the inability to speak English, and the ability to speak Welsh are all highly correlated (r = .90 or better), so there is no significant difference between the three measures for a preliminary analysis. Welsh speaking proved to be highly correlated with support for the Plaid in the four most recent general elections—r^2 equals .52 for 1970; .40 for February, 1974; .55 for October, 1974; and .60 for 1979. Three constituencies (Caernarvon, Carmarthen, and Merioneth) account for a major portion of the high level of association. There are large numbers of Welsh speakers, and the Plaid has achieved its highest level of support in these three constituencies, winning two of them in February, 1974, all three in October, 1974, and two in 1979. These have been the only seats the party has won in general elections. The correlation of lower levels of Welsh speaking and support for the nationalists is weaker with these three constituencies removed. The variance explained drops to .19 for 1970; .31 for February, 1974; .43 for October, 1974; and .32 for 1979. Thus, the relationship is weaker but still present, particularly for October, 1974. In the final analysis, identification with Welsh culture (as indicated by language ability) is an important determinant of support for the Plaid, but insufficient alone. These findings would support the need for studies like Ragin's (1979) to discover other attributes associated with support for the Welsh nationalists and for ethnic mobilization, in general, and they also indicate the advisability of using better levels of spatial input when possible and avoiding the problems presented by missing observations.

AGGREGATION GAIN AND LOSS IN ELECTORAL RESEARCH*

(A RESPONSE TO LUTZ'S COMMENT)

While Lutz's comment on my article is almost entirely speculative, it does raise some interesting issues. This response to Lutz's comment gives me an opportunity to demonstrate techniques that remedy the problems Lutz mentions. Before presenting these analyses, I first discuss Lutz's statements concerning my article and point out some of the problems and weaknesses in his speculations.

Lutz first argues that the observational units (counties) I use in my analysis, however necessary from a data availability standpoint, are not adequate because they are larger than the fundamental British electoral unit (the constituency) and contain vastly different numbers of constituencies (up to 16). He suggests that my aggregation of constituencies to counties may have obscured important sources of variation since the different constituencies contained within a multiconstituency county are unlikely to be homogeneous. He notes, for example, that the county of Glamorgan, with 16 constituencies, "may" contain as much variation in socioeconomic conditions relevant to ethnic mobilization as exists in Wales as a whole (Lutz, 1980:2).[1]

---

[1] Lutz comments that aggregating at the county level for Glamorgan combines urban areas, semi-urban areas, rural areas and "the mining valleys of

While it is true that aggregation generally compresses or reduces variation, this result is in no way automatic.[2] The fact of variance reduction must be established in each separate case. In Wales, for example, there are whole counties that are almost entirely rural and agricultural, and, despite Lutz's protests to the contrary, the fact remains that Glamorgan is predominantly urban and industrial. Indeed, students of Welsh politics and society typically distinguish between the rural north of Wales, comprising a majority of the counties of Wales, and the urban, industrial south, comprising the counties of Glamorgan and Mommouth and parts of other counties. In short, there is a great deal of variation among the counties of Wales in terms of socioeconomic composition, perhaps as great as the variation among the constituencies. The argument that a particular aggregation has compressed variation must be established empirically, not by ad hoc speculation.

Lutz's argument concerning my use of county data also ignores the fact that my analysis was both cross-sectional and longitudinal. Even if important sources of variation were obscured by the aggregation of constituencies to counties, the fact remains that I examined longitudinal variations within counties by pooling cross-sectional and time-series variations. In the analysis of Liberal Party support, for example, each county is observed at 10 points in time (1935 to 1974); in the analysis of Plaid Cymru support each county is observed at 8 points in time (1950 to 1974). Dramatic variations in the socioeconomic conditions relevant to ethnic political mobilization occurred in these counties over this period.

The second point raised by Lutz concerns my handling of "missing" data (Lutz, 1980:1). Because minor parties are often strapped for funds, they frequently are not able to contest every constituency election. When there is no candidate in a constituency election, the party, of course, receives no votes, and in the statistical analysis the party is coded as having received 0% of the votes cast. Lutz argues that this procedure probably underestimates the support for a party in such constituencies for, if the party had fielded a candidate, it surely would have received more than 0% of the vote. Thus, Lutz speculates that this procedure introduced a margin of error in my analysis.

There are several problems with Lutz's argument. First, it should be noted that I did not use constituency results in my analysis; I used county results. One could speculate that the aggregation of constituencies to counties resulted in aggregation *gain* (see below) and removed possible biases introduced by using the 0% coding for failure to compete. Second, I should point out that Lutz's presentation of information—on the extent to which the Liberal Party and the Plaid Cymru failed to compete in Welsh constituencies—is extremely selective. He reports data on the 1950 to 1966 period (Lutz, 1980:4). During this period, support for the Plaid Cymru was slight and scattered. It was after the election of 1966 that this party experienced a period of real growth. In fact, in the elections of 1970 and 1974 the Plaid Cymru contested every constituency election in Wales. Also during the 1950 to 1966 period, the Liberal Party was almost eliminated from British politics. The Liberal Party contested few elections because its chances of winning any of them were so slim. Before 1950, of course, the Liberal Party contested almost all constituency elections in Wales, a fact Lutz fails to mention, and after the rebirth of Welsh nationalism in the late 1960s, the Liberal Party contested many more elections in Wales than it had in the 1950 to 1966 period. In 1974, for example, the Liberals contested 31 out of 36 constituency elections in Wales. Thus, Lutz's focus on the 1950 to 1966 period seriously distorts the available data on patterns of candidature, especially considering the fact that the post-1966 (Liberal and Plaid Cymru) and the pre-1950 (Liberal) periods were responsible for the largest portion of the variation in the measures of party support I used in my analysis.

Another problem with Lutz's argument is that he ignores features of the British electoral system that favor the 0% coding. Electoral laws in Britain force minor parties to compete only in constituencies where there is likely to be at least a minimal level of support for their candidates. Every candidate is required to put up a substantial monetary deposit in order to be listed on the ballot in a constituency election. If she/he fails to win at least 12.5% of the poll, then the deposit is forfeited. In effect, the law compels minor parties unable to finance deposits for their candidates in every constituency to assess the socioeconomic and political conditions of each constituency and to determine where the party's money might best be risked. The fact that minor parties, such as the Plaid Cymru and, since 1931, the Liberal Party, most often forfeit a majority of their deposits suggests that these parties put up deposits (and candidates) in every constituency where they

---

the south" (1980:3). It should be noted, to avoid confusion, that the mining areas are located in the northern part of Glamorgan.

[2] This discussion of variance reduction sets aside, for the present, the relationship between weighting and reduction.

have even an outside chance of reaching the 12.5% minimum. In the election of 1966, for example, the Plaid Cymru contested 20 constituency elections in Wales and lost 18 of their deposits. Their lowest poll was 1.9% (in East Flintshire). These data suggest that (1) a party's decision not to field a candidate in a particular constituency must reflect a perceived lack of support in the constituency, and (2) the 0% coding that the party receives in such cases may be a rough, though certainly conservative, estimate of the poll it would have received if it had actually contested the election.[3]

The third issue raised by Lutz concerns the matter of tactical voting. In some constituency elections, only one of the two minor parties (Liberal and Plaid Cymru) put up candidates. Thus, supporters of the Liberal Party may have voted for the Plaid Cymru candidate in the absence of a Liberal Party candidate, and *vice versa*. This is an important issue, especially considered in the context of the second issue raised by Lutz. In my original article I argued that, even though both minor parties claim to represent the interests of Wales as a whole, the bases of support for the two parties differ. Lutz suggests, however, that the combined effect of tactical voting decisions and uneven availability of candidates may have been to create artificial differences between these two parties in the analysis of the various bases of their support.

While this is an interesting speculation, there are several problems with it. First, it should be noted that the Liberal Party in Wales, especially since 1964, generally has contested a subset of the seats contested by the Plaid Cymru and that in most elections there is a weak, *positive* relationship between the presence of a Liberal candidate and the Plaid Cymru percentage of the vote. Thus, the Plaid Cymru tends to be more aggressive than the Liberal Party in putting up candidates, but it has not benefited from the failure of the Liberal Party to put up candidates in some Welsh constituencies. Another problem with Lutz's argument is that his presentation of data is, again, very selective. Lutz (1980:4–6) focuses on the 1950 to 1966 period, when in fact the real resurgence of Welsh nationalism and the support for these two parties came *after* 1966. In my analysis of the support for these parties the greatest contribution to the total variation in their support came from the 1970 and 1974 elections. In these two elections overlapping candidatures were by far the rule, not the exception.

One possibility not considered by Lutz is that aggregation *gain* may have resulted from my procedures. Suppose county A is composed of two constituencies, A1 and A2, and that these two constituencies differ in socioeconomic composition. In A1 Liberals think that they have a good chance of avoiding a forfeiture of their deposit and put up a candidate, while in A2 they perceive a probable lack of support and do not put up a candidate. Suppose further that the reverse is true for the Plaid Cymru, and they put up a candidate in A2 but not in A1. If tactical voting forces some Plaid Cymru supporters in A1 to vote for the Liberal Party and some Liberal Party supporters in A2 to vote for the Plaid Cymru, then Plaid Cymru support will be underestimated in A1 (0%) and overestimated in A2, while Liberal Party support will be underestimated in A2 (0%) and overestimated in A1. To aggregate these two constituencies together and compute county-wide percentages, however, may yield accurate measures of Plaid Cymru and Liberal support (at the county level) because the aggregate measures would combine overestimates and underestimates. Uncorrected for patterns of candidature, the constituency-level measures would produce distorted results. True, this line of reasoning is completely speculative, but it is no less speculative than Lutz's comment.

Speculative discussion, however, is no substitute for empirical research. Most of the issues Lutz raises can be addressed only with appropriate constituency-level data. Lutz laments their absence. Some constituency-level data have been made available, however, by Great Britain's General Register Office. While these data are only roughly comparable to the data I used in my study, they allow a reanalysis of the social bases of the support for the Liberal Party and the Plaid Cymru at the constituency level.

Before I discuss the nature of my reanalysis, I should point out the shortcomings of these data. (1) They are recent data, and they are available for only one point in time. Thus, in my reanalysis I examine only the elections of 1964, 1966, 1970 and 1974. (2) The data are not detailed enough to allow the construction of measures comparable to those used in my article. A key variable in that article was an occupational composition measure indicating the proportion of the labor force employed in advanced sector jobs in the tertiary and in modern industries (that is, nonperiphery industries). It is impossible to duplicate this measure with the constituency data supplied by the General Register Office. As a substitute for the measure of advanced sector employment, I constructed an estimate based on the relationship between tertiary employment and manufacturing employment.

---

[3] Another way to look at this issue is to consider any measure of party support that incorporates the 0% coding (for failure to contest) a compound measure. With the 0% coding two pieces of information are combined in the measure of party support: (1) whether or not the minor party perceived any possibility of support (0 versus any other number), and (2) the actual percentage of the vote received by the party if it perceived any possibility of support. Both pieces of information are relevant to party support; the compound measure may be even superior.

The reanalysis I present below answers all of Lutz's speculations. The fact that I use constituency-level data in the reanalysis obviously answers the first speculation, that my findings may have been shaped by the necessity of using county-level data. Lutz's second speculation, that the 0% coding of failures to contest elections may have biased my findings, is answered in two different ways. In one analysis I use two dichotomously coded variables (No Liberals and No Plaid Cymru) to control statistically for the absence of candidates. When the Liberal Party failed to compete in a particular constituency election, for example, No Liberal is coded 1. Otherwise, No Liberal is coded 0. A parallel procedure is used in the coding on No Plaid Cymru. These variables are used in the analysis to control for the effects of differential patterns of candidature. In another analysis I answer Lutz's second speculation by performing a separate statistical examination of constituencies with overlapping candidatures. In this analysis the number of observations is reduced from 144 (36 constituencies × four elections) to 69. Lutz's third speculation concerns the problem of tactical voting. The two solutions to the problem of the 0% coding of failures to contest elections answer this speculation. The question of tactical voting, however, also touches a larger issue only briefly discussed by Lutz. In his discussion of the tactical voting problem, Lutz suggests that the social bases of the support for the Liberal Party and the Plaid Cymru may be identical, or at least very similar. Given the fact that both parties claim to represent the interests of Wales as a whole, this fourth, implicit speculation warrants close examination.

Unfortunately, it is not possible to address this fourth speculation convincingly simply by adding the support for the Plaid Cymru to the support for the Liberal Party and running a third statistical analysis. This method does not really *test* the degree to which the social bases of the support for the two parties differ. As an alternative I propose using canonical correlation analysis. With canonical correlation analysis it is possible to examine the dimensionality of a set of interval scale dependent variables as they relate to a set of independent variables (see Cooley and Lohnes, 1962). Canonical correlation analysis proceeds in a stepwise fashion, extracting orthogonal canonical variates one at a time. An important feature of canonical correlation analysis is that it derives a linear combination from each of two sets of variables in such a way that the correlation between the two linear combinations is maximized, and canonical weights for independent and dependent variables can be computed. This feature of canonical correlation analysis makes it possible for the researcher to assess the interrelationships among a set of dependent variables *relative to* a given set of predictor variables and their interrelationships. Another important feature of canonical correlation analysis is that it allows the researcher to perform tests of statistical significance on the orthogonally extracted canonical variates. In an analysis of two dependent variables, for example, two canonical variates are extracted. If the second variate does not account for a statistically significant portion of the variance in the dependent variables, it is rejected.

In order to examine the hypothesis that the social bases of the support for the Plaid Cymru and the Liberal Party are identical, or at least very similar, I use measures of the support for these two parties as multiple dependent variables in canonical correlation analyses. With two dependent variables several patterns of results are possible. Only one pattern supports the argument that the social bases of the support for these two parties are similar. This argument is supported when just the first canonical variate is statistically significant *and* both measures of party support correlate strongly (and in the same direction) with the first variate. This is not the pattern I would predict on the basis of my earlier work, however. In my article I show that even though the parties compete for the support of similar sets of voters (see, e.g., Ragin, 1979:626, Table 3), there are several differences in the bases of the support for these two parties. The Liberal Party tends to do better in agricultural areas, while the Plaid Cymru tends to do better in areas where there is a greater persistence of Welsh traditionalism—for example, noncomformity or Welsh-speaking, in areas where there is higher percentage of the labor force employed in advanced sector occupations, and in areas that combine these two features. On the basis of the similarities and differences discussed in my article, I predict two significant canonical variates, one showing similarities in the support for these two parties and one showing differences.

I report the results of my test of these competing speculations in Table 1. The dependent variables in the canonical analyses are the percentage of voters in each constituency supporting the Plaid Cymru and the percentage supporting the Liberal Party. The independent variables are the percentage of the labor force employed in agriculture, the estimate of the percentage of the labor force employed in the advanced sector (mentioned earlier), the percentage of the population of each constituency able to speak Welsh (from Lutz, 1980), the multiplicative interaction of the advanced sector employment measure and the measure of Welsh-speaking (following the results reported in Ragin, 1979:631, Table 5), the dichotomous variables (described above) that act as controls for patterns of candidature, and dichotomous variables that control for the differences in the levels of support for these two parties across elections. (Election 66 is coded 1 if the party support measures are from the 1966 election and 0 otherwise, etc. The 1964 election is the omitted category.) The results of three separate canonical correlation analyses are reported. The first reports the results that are obtained when no controls for patterns of candidature are included. This analysis shows the consequences of accepting the 0% coding as a valid estimate of a party's support in constituencies where it fails to put up candidates. The second analysis includes the controls for patterns of candidature. The third reports the results of an analysis of constituencies with overlapping candidatures (see above).

In general, the results reported in Table 1 support those I presented in my original article (Ragin, 1979) and they provide additional support for my contention that there are important differences in the social bases of support for the Plaid Cymru and for the Liberal Party. The coefficients for the dependent variables in each analysis show that there are both similarities and differences in the support for these two parties. In each analysis the first canonical variate shows the similarities in their support while the second variate shows the differences. Also, in each analysis, both the first and the second canonical correlations are very strong and highly significant. The analysis that gives the least support to the argument that there are strong similarities in the support for these two parties is the second analysis. This analysis uses information on all 144 constituency elections and includes controls for patterns of candidature. The results of this analysis suggest that controlling for patterns of candidature may increase the statistically discernible differences between the two parties. This finding directly contradicts Lutz's speculation. The results of the third analysis, which includes only constituencies with overlapping candidatures, however, shows that the alternative solution to the problem of differential patterns of candidature presents somewhat different results. The similarities between the parties reported in the third analysis, however, may be the product of the selection mechanism that was used

Table 1. Canonical Correlation Analysis of the Effects of Welsh-Speaking, Agricultural Employment and Advanced Sector Employment on Liberal Party and Plaid Cymru Support, Constituency Data: 1966–1974

	CONDITIONS					
	I. No Controls for Patterns of Candidature (N = 144)		II. Controls for Patterns of Candidature (N = 144)		III. Constituencies with Overlapping Candidature only (N = 69)	
Variables	Canon. Var. 1	Canon. Var. 2	Canon. Var. 1	Canon. Var. 2	Canon. Var. 1	Canon. Var. 2
%Agricultural	.490	−.964	.420	−.380	.542	−.702
%Advanced Sector*	.003	−.373	−.061	−.147	−.102	−.148
%Welsh-Speakers	−.001	.436	−.307	.429	−.083	.839

%Liberal	.750	−.670	.888	−.473	.745	−.671
%Plaid Cymru	.586	.818	.375	.933	.727	.691
Canonical Corr.	.889	.602	.931	.745	.905	.724
Significance	.000	.000	.000	.000	.000	.000

* %Advanced Sector employment has been estimated; see text.

to define the subset of constituencies on which the analysis is based.

The size and direction of the canonical coefficients attached to the independent variables are fairly consistent across the three analyses and with my (Ragin, 1979) article. In each analysis: (1) %Agricultural has a strong positive effect on the similarities and a strong negative effect on the differences between Plaid Cymru support and Liberal support (%Plaid Cymru—Liberal), (2) %Advanced Sector has a weak, inconsistent effect on both similarities and differences, (3) %Welsh-Speakers has a strong positive effect on differences, and (4) the multiplicative interaction between Welsh-speaking and advanced sector employment (Interaction AS×W) has a strong positive effect on both similarities and differences. This last finding suggests that the joint effect of advanced sector employment and Welsh-speaking is to increase the support for both parties and to increase the lead of the Plaid Cymru over the Liberal Party. This seemingly contradictory pattern must be understood in the context of the fact that both of these parties are minor parties and that in some areas of Wales neither party does very well. In general, the findings support the interpretations of Welsh ethnic political mobilization I presented in my article.

Even though my reanalysis supports my original analysis and the decisions and assumptions on which it was based, in general the superiority of constituency data must be admitted. Unfortunately, adequate constituency data are not available for *historical* research. In my (Ragin, 1979), article my objective was to characterize ethnic political mobilization in Wales over the 1935 to 1974 period. Historical *county* level data were the only data available for this task; the crude constituency data that do exist are available for only one relatively recent point in time. I hope the results of my reanalysis encourage those willing to work with available historical materials to persist in their efforts to apply quantitative techniques to historical data.

ITEMS

■ With this issue I end my stint as editor of the *American Sociological Review*. Looking back over the three years, I realize that the objectives I had when I first began remained the same throughout my term. I wanted to publish papers that would have lasting value in many different areas of sociology. Theoretical and historical pieces were sought after as much as were papers using the most up-to-date quantitative techniques. The basic question remained: Is it important, does it matter?

I thought that we should make room for pieces that needed more than the standard thirty manuscript pages—hence, the twenty-page expansion; and I also wanted to encourage shorter, less developed or polished pieces—hence, the section on research notes.

The biggest reward I received as editor was that I learned a lot about the kinds of research sociologists are engaged in, the directions sociology seemed to be moving in, and what the major issues are. I discovered there is quite a bit of disagreement over what constitutes an important or competent piece of work and that those disagreements weren't limited to any particular subfields. I also learned that a great many busy people were willing to take the time to write detailed, thoughtful reviews from which authors were able to benefit even if their papers were not published in the *American Sociological Review*.

I want to acknowledge with appreciation and thanks the help that I received from several colleagues and staff members. Most of all I want to thank Linna McDade and Clark McPhail who stayed on as Managing Editor and Deputy Editor for the full three years. Linna did a superb job of managing the office, keeping the manuscripts moving, and responding to irate and upset authors with sympathy and understanding. Clark McPhail played an important role in assigning manuscripts to readers and in advising me on their final disposition. Joe Spaeth shared these tasks for the past year and I am very grateful for his help and sound advice. Rafe Stolzenberg served as a deputy editor during my first two years, and his time and efforts are appreciated.

We were fortunate in having the services of two first-rate copy editors—Mary Mander, for the first two years, and Elizabeth Neumann, in the third year, performed wonderfully under all kinds of time pressures. They managed to satisfy authors, editors, and printers.

Finally, I want to express my appreciation to my advisory editors, to all of you who reviewed manuscripts, and to Henry Quellmalz who somehow always managed to get an issue out faster than we thought possible.

■ PETER H. ROSSI (The Presidential Address) is Professor, Department of Sociology, and Director, Social and Demographic Research Institute, University of Massachussetts at Amherst. Among his fields of research are state and local political elites and the politics of land-use regulation: His *Handbook of Survey Research* (with Wright and Anderson) will be published in 1981 by Academic Press.

■ IVAN D. CHASE (Social Process and Hierarchy Formation in Small Groups) is Assistant Professor, Department of Sociology, State University of New York at Stony Brook. His current research combines empirical techniques and theoretical approaches from the social sciences and animal behavior to increase understanding of social inequality in both humans and animals; studies hierarchy formation further, using larger groups; and (using microeconomic methods) examines biological theories of "cooperative" behavior in animals.

■ RANDALL COLLINS (Weber's Last Theory of Capitalism: A Systematization) is Professor, Department of Sociology and Center for Advanced Studies, University of Virginia. He is comparatively analyzing social determinants of philosophy and mathematics in various historical societies. His books, *Sociology Since Mid-Century*, with Norbert Wiley (Academic Press, and *Non-Obvious Sociology: An Introduction to Sociological Thinking* (Oxford University Press) are forthcoming.

■ JOHN H. RALPH (Immigration and the Expansion of Schooling 1890–1970) is Assistant Professor, Department of Educational Studies, University of Delaware, where he is conducting a longitudinal study of school determinants in the United States with special attention to interest in political developments and school change at the turn of the century. RICHARD RUBINSON is Associate Professor, Department of Social Relations, Johns Hopkins University. He is studying processes of political transformation in the capitalist world economy in the nineteenth century, and is also conducting research in historical studies of educational expansion.

■ L. RICHARD DELLA FAVE (The Meek Shall Not Inherit the Earth) is Associate Professor, Department of Sociology and Anthropology, North Carolina State University. He is developing research to test empirically propositions set forth in the present article, as part of a larger project through which stratification is legitimated. Other research deals with the determinants of ethnic boundary maintenance. Also, he and Harold R. Kerbo have just completed a study of the concentration of stockvoting rights in major U.S. corporations.

■ HARVEY M. CHOLDIN (Suburban Status Instability) is Professor, Department of Sociology, University of Illinois at Urbana-Champaign. Current research centers on sociability and social change in suburbs and city neighborhoods. Forthcoming from Academic Press (and edited with Michael Micklin) is *Sociological Human Ecology*. CLAUDINE HANSON is a Ph.D. candidate, Department of Sociology, UIUC. She is researching determinants of urban subcommunity status as well as judgments of equity among poor, middle-class and rich Americans. ROBERT BOHRER is Professor, Department of Mathematics, University of Illinois at Urbana-Champaign. A mathematical statistician, he is working on simultaneous inference; statistical computing; and applications of time-series methods in psychophysiology.

■ MARILYN LESTER (Generating Newsworthiness) is Associate Professor, University of Nevada at Las Vegas. Other current interests include research and theoretical development in the field of properties of intimate experiences. ROBERT SCHLAIFER (Comment on Franke and Kaul) is William Ziegler Professor of Business Administration, Graduate School of Business Administration, Harvard University. He is currently researching Computerized Data Analysis.

■ JAMES M. LUTZ (Comment on Ragin) is Assistant Professor, Department of Political Science, Iowa State University. From Praeger (1978) came his book (written with Robert T. Green), *The United States and World Trade: Changing Patterns and Dimensions*. He is researching international terrorism and delving into the aspects of political/economic interactions (international level), including third-world dependency.

THE OLDER WOMAN

New!

Lavender Rose or Gray Panther

Edited by **Marie Marschall Fuller,** *Texas Woman's Univ., and* **Cora Ann Martin,** *North Texas State Univ., both of Denton. (41 Contributors)* The thirty-three articles in this anthology present a sociological view of the unique problems and needs of the older woman in today's society. Special emphasis throughout the book is on the recognition of individuality and on the evolving role of women.

Following a broad profile of older women in contemporary America, the book is divided into seven sections as follows:

Part One offers a statistical description of the older woman, including employment patterns, marital status, and numbers.
Part Two underscores the socialization process of women and their varying responses to changing times.
Part Three examines biological facts and fallacies related to sex, menopause, health, and mental health.
Part Four explores the social bonds that tie older women into meaningful interpersonal relationships. Marriage, widowhood, familial relationships, and friendships are discussed.
Part Five focuses on older women and traditional institutions of society—family, economy, politics, religion, and education.
Part Six discusses lifestyles that characterize the older woman.
Part Seven forecasts the position of the older woman in tomorrow's world.

'80, 368 pp., 19 tables, $16.75, paper

A Society in the Making

Hungarian Social and Societal Policy 1945-75

By Zsuzsa Ferge   Preface by S. M. Miller

"... a milestone in social policy analysis.... an enormously rich melding of social policy perspectives developed by writers like Marshall and Titmus with systematic Marxist analysis. Ferge's approach provides a rich paradigm for social policy analysts of the future."

$22.50 —*Lee Rainwater, Harvard University*

Neocolonial Identity and Counter-Consciousness

Essays on Cultural Decolonization

By Renato Constantino   Edited with an introduction by István Mészáros

"... the first fundamental assessment of cultural imperialism.... a major classic in the field.... (The author) has brilliantly explored the foreign-defined educational system and values that become the vehicles for cultural identity.... a major, brilliant effort..." —*Gabriel Kolko, York University*

$20.00

Socialist Population Politics

The Political Implications of Demographic Trends in the USSR and Eastern Europe

By John F. Besemeres

"... a bold and fascinating political analysis of the implications ensuing from the current and pending shifts in the population of the USSR, Poland and Yugoslavia.... Besemeres fills a gap between ideology, domestic and international politics, and demography with particularly interesting materials and speculation." —*Murray Feshbach, Fellow/The Wilson Center*

$25.00

Soviet Work Attitudes

The Issue of Participation in Management

Edited by Murray Yanowitch

"Important reading for anyone who wants to know what the Soviet Union is really like. It reports on major and reliable research by Soviet social scientists."

$15.00 —*Seymour Martin Lipset, Stanford University*

Chinese Approaches to Family Planning

Edited with an introduction by Leo A. Orleans

"A fascinating and important view of what Chinese leaders are telling their people to educate them about family planning.... a major contribution to increasing our understanding of China."

$18.00 —*Ronald Freedman, University of Michigan*

Scratches on Our Minds

American Views of China and India (Previously reprinted as *Images of Asia*)

By Harold R. Isaacs

"... a seminal book, and one which might profitably inspire a flood of similar inquiries into our ideas of other regions.... Mr. Isaacs' painstaking research should go far toward reducing misunderstandings arising from sheer ignorance and from uncontrolled emotion." —*The Annals of the American Academy of Political and Social Science*

DORSEY

Quality texts for 1981....

CONTEMPORARY SOCIAL PROBLEMS
Robert R. Bell, *Temple University*

Focuses on how social problems emerge over time and examines their various stages.

HUMAN RESPONSES TO SOCIAL PROBLEMS
Louis Schneider, *late of the University of Texas at Austin,* **Cookie White Stephan,** *New Mexico State University,* **Louis A. Zurcher, Jr.,** and **Sheldon Ekland-Olson,** *both of the University of Texas at Austin*

Unprecedented new text focuses on how people define, analyze, and attempt to deal with the issues and events in society which they consider to be social problems.

THE EMERGENCE OF SOCIOLOGICAL THEORY
Jonathan A. Turner, *University of California - Riverside,* and
Leonard Beeghley, *University of Florida*

Summarizes and analyzes the intellectual origins, profile and theoretical implications of 19th and early 20th century social thinkers.

Examination copies for adoption consideration available on request.
Please indicate course title and text presently used.

THE DORSEY PRESS

A NEW WAVE
of Sociology Texts for 1981

PROBLEMS OF AN INDUSTRIAL SOCIETY, 2/e
WILLIAM A. FAUNCE, Michigan State University
256 pages (tent.), $8.95 (tent.)

Within an historical and developmental framework, this new edition examines a wider range of problems found in industrial societies, including problems of the aged and resource depletion.

INTRODUCTION TO SOCIAL POLICY
ELIZABETH D. HUTTMAN, California State University, Hayward
420 pages (tent.), $14.95 (tent.)

This new text clearly presents social policy concepts and then applies them to particular social welfare areas, emphasizing the real-world function of social policy.

INTRODUCTION TO SOCIAL RESEARCH, 3/e
The late **SANFORD LABOVITZ**; and **ROBERT HAGEDORN**,
University of Victoria, Canada
176 pages (tent.), $8.95 (tent.)

This successful text provides a broad, integrated treatment of basic concepts and key research ingredients of social research.

THE URBAN WORLD, 2/e
J. JOHN PALEN, Virginia Commonwealth University
480 pages (tent.), $17.95 (tent.); Instructor's Manual

Substantially revised, the second edition features solid, readable coverage of recent trends in urban sociology and retains the cross-cultural perspective of the first edition.

MEN, WOMEN, AND CHANGE: A Sociology of Marriage and Family, 2/e
LETHA DAWSON SCANZONI and **JOHN SCANZONI**,
University of North Carolina, Greensboro
608 pages (tent.), $17.95 (tent.); Instructor's Manual

Solidly grounded in sociological theory, the new second edition provides a practical framework for understanding the dynamic process involved in premarital, marital, and alternative relationships.

SOCIOLOGY: The Human Science, 2/e
ELBERT W. STEWART
656 pages (tent.), $18.95 (tent.); Instructor's Manual; Test File; The Examiner System, a computerized test-generation system

A book for the 1980s, the second edition adopts social change as its integrating theme, addresses important new developments, and offers an excellent built-in Study Guide at the end of every chapter.

THE NATION'S FAMILIES: 1960-1990

George Masnick, Harvard University
Mary Jo Bane, Harvard University

Foreword by **David T. Kresge,** Director of the Joint Center
for Urban Studies of MIT and Harvard University

The Nation's Families: 1960-1990 identifies current population, household, and lifestyle trends and interprets their implications for future policy planning and institutional accommodation. The authors set aside several misconceptions about recently observed changes in the American family and suggest changes in store over the next decade. Among the factors of family life measured and projected are principal householders' marital status, household structure, women's participation in the labor force, contributions to household income, personal relationships, and lifestyles. Special attention is given to trends and differentials in the behavior of birth cohorts as they age over the life course. The text is highlighted by over 50 graphs and tables.

HARDBOUND EDITION, 1980 ISBN 0-86569-050-2 $17.95

The Annenberg School of Communications

The University of Pennsylvania
Philadelphia

A graduate program for new careers in communications scholarship, research and policymaking.

A select group of candidates for the Master of Arts and the Ph.D. in Communications learns the theories and methods of scholarship in interpersonal and mass communications; visual communication and cultural analysis; and media management and regulation.

The program is designed for the superior student in the humanities and social sciences. It provides the guidance of a distinguished faculty, academic resources of a major research university, and the financial aid needed to pursue full-time study. Recent graduates have assumed posts in scholarly and scientific institutions; government, business and industry; and media research and management.

For information write Admissions, The Annenberg School of Communications, 3620 Walnut Street, Philadelphia, PA. 19104 or call (215) 243-7041.

The Annenberg School of Communications at the University of Pennsylvania welcomes applicants without regard to race, color, sex, sexual or affectional preference, age, religion, national or ethnic origin or physical handicap.

Teenage Sexuality, Pregnancy, and Childbearing

Frank F. Furstenberg, Jr., Richard Lincoln, and Jane Menken, Editors

Examining the social consequences of teenage childbearing, the editors explain, in particular, the effects on adolescent parents themselves, their offspring, and their families. These essays search for the determinants of early parenthood, consider the means for preventing premature childbearing, and discuss ways of tempering its consequences.

This comprehensive and useful book reviews the new evidence on the economic, political, and social impact of teenage sexual activity on our society. Twenty-eight key reports provide a concise collection of reference material with an up-to-date bibliography at the end of each selection.

(Formerly New Viewpoints)

Feb. 1981 **Juvenile Delinquency and Juvenile Justice**

JACK KLEMPNER, Avila College, Kansas City, and RODGER D. PARKER, Univ. of Missouri, Kansas City. The authors, former probation officers, analyze the causes of increasing juvenile delinquency and the failure of the present juvenile justice system. They offer practical proposals for reforming the system and coping with the underlying social problems.

$13.95 (tent.) Hardcover 531-05419-5

Jan. 1981 **Aging in a Changing Society** *2nd Ed.*

ZENA SMITH BLAU, Univ. of Houston. Enriched by a new study of the needs of 60,000 Texans over 55, this widely acclaimed book shows that society has "as yet found no ways to use the qualities, talents, and skills of its aging citizens," and presents many new ways this can be accomplished. The first edition was "highly recommended" by *Choice* "for both undergraduate and graduate levels. A must for those involved in gerontological studies and teaching."

a sound introduction to . . .

THE SOCIAL WELFARE INSTITITUION:
An Introduction, Third Edition

Ronald C. Federico, *University of Cincinnati*
1980, Cloth, 416 pages, Instructor's Guide

This text continues to provide beginning students with a conceptual understanding of the scope and major components of the social welfare institution and the profession. The Third Edition examines the meaning of social welfare and the characteristics of social welfare as a social institution. An analytical framework aids student understanding of the approaches to social welfare services.

CRIMINOLOGY: Perspectives on Crime and Criminality

Peter Wickman, *State University of New York, Potsdam and*
Phillip Whitten with the assistance of Robert Levey
1980, Cloth, 640 pages, Instructor's Guide

Written for the beginning student in criminology, the text covers major perspectives, issues, and the diverse concerns and debates that characterize contemporary criminology. The balanced "humanistic" view of criminology that is critical as well as current is designed to stimulate the student's systematic study of crime, criminality and criminal behavior.

DELINQUENCY: A Sociological View

Gary F. Jensen, *University of Arizona*
Dean G. Rojek, *University of Georgia*
1980, Cloth, 416 pages, Test Item File

This text presents a systematic sociological analysis of juvenile delinquency with careful attention given to treatment and prevention. It examines the origins of adolescent misbehavior; appraises society's reaction to the problem; and discusses the success of the current system of juvenile justice in dealing with the problem.

A SOCIAL INSTITUTION . . .

New for 1981

Coming in February!

THE SOCIOLOGY OF DEVIANCE: An Introduction by Jack D. Douglas & Frances Chaput Waksler. Cloth/c. 512 pages/$16.95 tentative/with Test Bank. *Incomparably up-to-date,* this innovative new text is unique for its use of the "new perspective" (e.g., symbolic interactionism, labeling theory) as both an analytical tool and a unifying theoretical framework. Its *thorough coverage* of the key topics in deviance incorporates the very latest approaches, and it introduces a *wholly new subject:* cognitive deviance (e.g., religious cults, supernaturalism).

Coming in January!

INTRODUCTION TO CRIMINOLOGY, 2nd Edition, by Hugh D. Barlow. Cloth/c. 576 pages/$16.95 tentative/with Instructor's Manual. In its new edition, this *descriptive* introduction to theory and method in criminology, crime and criminal offenders, and criminal justice continues to stress the importance of social and historical context. Thoroughly updated, the Second Edition features two separate chapters on punishment, plus *all-new* sections on child abuse, spouse rape, victimization, self-report studies, biogenic theories, and prosecution and sentencing.

Coming in January!

CITY SCENES: Problems and Prospects, 2nd Edition, edited by J. John Palen. Paper/c. 320 pages/$9.95 tentative. Such key issues as poverty, urban regeneration and displacement, race and ethnicity, and planning for the year 2000 are the focus of this widely-admired urban sociology reader. *Expanded and updated,* the Second Edition features 12 (out of 22) new articles and two entirely new chapters: "Neighborhood and Community" and "Patterns in Developing Countries."

Coming in February!

SOCIAL PROBLEMS: The Contemporary Debates, 3rd Edition, edited by John B. Williamson, Linda J. Evans & Anne Munley. Paper/c. 512 pages/$9.95 tentative/with Test Bank. This widely-used text/reader explores 17 social problems in a debate format that directly juxtaposes proponents of differing perspectives (e.g., conservative/liberal/radical). Among the 7 *new issues* debated in this Third Edition are family violence, the death penalty, nuclear power, and the prospects for affluence in America's future.

Little, Brown Texts and Readers

Recently Published

SOCIAL PROBLEMS by Burton Wright & John P. Weiss. Cloth/556 pages/$15.95/with Study Guide and Instructor's Manual. This new introductory text examines 15 contemporary problems within a *unique integrating framework:* how societal conflicts arise, how they're perpetuated, and how they might be resolved.

FAMILY IN TRANSITION: Rethinking Marriage, Sexuality, Child Rearing, and Family Organization, 3rd Edition, edited by Arlene Skolnick & Jerome H. Skolnick. Paper/579 pages/$9.95/ with Test Bank. In its new edition, the most widely-used Marriage and Family reader features *70% new material,* including articles on love, divorce, divorce law, and remarriage.

SOCIAL GERONTOLOGY: An Introduction to the Dynamics of Aging by David L. Decker. Cloth/304 pages/$14.95/with Test Bank. This new text analyzes recent demographic shifts to explore the significance of aging as a social phenomenon and explores a range of problems facing older Americans.

THE SOCIOLOGY OF HEALTH: Principles, Professions, and Issues by Fredric D. Wolinsky. Cloth/449 pages/$15.95. A comprehensive, readable survey of health-related behavior, this new text focuses on the major concepts, careers, and debates in medical sociology.

CONSCIENCE AND CONVENIENCE: The Asylum and Its Alternatives in Progressive America by David J. Rothman. Paper/464 pages/$8.95. This sequel to the prize-winning work, THE DISCOVERY OF THE ASYLUM, traces Progressive reform efforts in the realms of criminal justice, juvenile justice, and mental health.

PRISONS IN TURMOIL by John Irwin. Paper/277 pages/$6.95 A scholar and former inmate offers a fascinating, *inside account* of how prisoners cope with life behind bars, including an analysis of prison social structures.

HOUSE OF CARDS: The Legalization and Control of Casino Gambling by Jerome H. Skolnick. Paper/382 pages/$7.95. This study of Nevada's casino industry focuses on administrative and ethical problems in legalization and licensing.

Still available in cloth

Chicago Press

Human Nature and History

A Response to Sociobiology

KENNETH BOCK. In recent years a number of biologists—E.O. Wilson and Konrad Lorenz among them—have expanded their theories to include explanations of human social behavior. A response to this sociobiological analysis of human societies, *Human Nature and History* argues that an understanding of man's social and cultural differences is best sought in the pages of history, and not in biology or comparative ethology.

"An eloquent defense of historical processes as movers and shapers of mankind.... [Bock] has carefully marshalled his material and presents a well-developed thesis.... Withal, a worthy addition."—*Kirkus Reviews*

$18.95

Programmed to Learn

An Essay on the Evolution of Culture

RONALD H. PULLIAM AND CHRISTOPHER DUNFORD. "The sociobiologist asserts that man's behavior is determined by his genetic heritage; the psychologist maintains that man's behavior is determined by cultural heritage. Pulliam and Dunford propose a synthesis, based on the combination of genetic theory and cognitive consistency theory.... The educated layreader will find the book timely, accessible, and very readable."—*Library Journal*

sociology

Journal of the British Sociological Association

Quarterly

Editor: Professor Philip Abrams

SOCIOLOGY, the journal of the British Sociological association, is widely recognised as the leading British journal in the field, the journal which covers all that is of importance in British sociology, publishing articles which report the results of significant research together with speculative and controversial contributions to major sociological debates.

As well as major articles, there are sections for DEBATES, extended REVIEW ARTICLES, BOOK REVIEWS and SHORTER NOTICES.

Contributors to past issues have included: Basil Bernstein; Stan Cohen; Norbert Elias; Tony Giddens; John Goldthorpe; David Lane; David Lockwood; Steven Lukes; John Rex; Margaret Stacey; Peter Worsley.

SOCIOLOGY is published by the BSA in February, May, August and November

sociology

— a journal of exceptional academic quality —

To understand all levels of society, students need the highest level of scholarship.

21 OCT 1981

Coming this Spring—
CAVAN & FERDINAND

JUVENILE DELINQUENCY *Fourth Edition*

This completely revised edition offers a complete, factual account of delinquency that emphasizes the sociological aspects and also covers much of the latest psychological research. New features include: • material on the rapidly emerging problem of female delinquency • an examination of historical evidence regarding the foundation of juvenile justice upon *parens patriae* and its meaning for modern day juvenile justice • recent material regarding the community and delinquency.

New! KENKEL

SOCIETY IN ACTION **Introduction to Sociology, *Second Edition***

Emphasizes evolutionary theory and integrates this theme into the family, sex roles, stratification, and economic institutions. Also included are new chapters on the sociology of sex roles and human groups, new boxed inserts on contemporary issues, and more cross-cultural references. Study Guide and Test Bank. Instructor's Manual.

New! COLEMAN & CRESSEY

SOCIAL PROBLEMS

Combining functionalism with the conflict and social psychological approaches, this text covers more social problems than any other text available. Twelve "debates" argue the pros and cons of vital social issues. Instructor's Manual.

New! ACUÑA

OCCUPIED AMERICA **A History of Chicanos, *Second Editon***

Still the only available history of Chicanos written by a Chicano, this comprehensive, well-documented text now includes many new primary sources and offers a closer look at the economic causes of the Chicanos' subjugation.

New! PERRY & PERRY

CONTEMPORARY SOCIETY

An Introduction to Social Science, *Third Edition*

Extensively revised, this unique text/reader features: • a new chapter on sexuality and sex roles • a greatly expanded economics section • more integrated treatment of Marxism, capitalism, and socialism • and all-new readings, marginal notes, and chapter summaries.
